Hypo-sulphites. VII. Rongalite and Salts of Amines. ARTHUR BINZ and TH. MARX (*Ber.*, 1910, 43, 2344—2349. Compare Binz and Isaac, *Abstr.*, 1908, i, 940).—The hydrochlorides of amines react with rongalite even in the absence of formaldehyde. It is suggested that the hydrochloride first condenses with the sodium salt according to the equation

$\text{RNH}_2\cdot\text{HCl} + \text{OH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{S}\cdot\text{ONa} = \text{RNH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{S}\cdot\text{OH} + \text{NaCl} + \text{H}_2\text{O}$, and that the substituted formaldehydesulphoxylic acid then forms a salt with the excess of the amine hydrochloride:

$\text{RNH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{S}\cdot\text{OH} + \text{RNH}_2\cdot\text{HCl} = \text{RNH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{S}\cdot\text{O}\cdot\text{NH}_2\text{R} + \text{HCl}$, and that it is this salt which is precipitated. In the case of ammonium chloride and of hydroxylamine hydrochloride, it has been found possible to isolate the intermediate product. The salts are decomposed by cold dilute sodium hydroxide solution, and practically half the amine used up in the formation of the compound is liberated.

Rongalite and *o*-toluidine hydrochloride yield the salt

in the form of colourless crystals, m. p. 101—104°. It turns a yellow colour on exposure to the air, and reduces warm indigocarmin solution. When an excess of rongalite is used, mixtures are formed.

Rongalite and anthranilic acid hydrochloride yield colourless crystals of the compound $\text{C}_{15}\text{H}_{16}\text{O}_6\text{N}_2\text{S}$, m. p. 143° (decomp.). When diazotised, it yields salicylic acid, and when oxidised with hydrogen peroxide or with sodium thiosulphate yields anthranilic acid. Rongalite and hydroxylamine hydrochloride in the presence of formaldehyde solution yield *hydroxylaminomethylsulphurous acid*, $\text{OH}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO}_2\text{H}$, owing to the oxidising action of the hydroxylamine. It can be crystallised from water, does not reduce indigocarmin, and has m. p. 191°.

J. J. S.

Preparation of Thiodiphenylamine and its Derivatives. FRITZ ACKERMANN (D.R.-P. 224348).—The preparation of thiodiphenylamines with the aid of sulphur and aluminium chloride has previously been described; it is now found that aluminium bromide or iodide, ferric chloride, antimony trichloride, cuprous iodide, sulphur iodide, or iodine can be employed equally well, and the methods of doing so with their extension to the preparation of thio- β -dinaphthylamine and thio-phenyl- β -naphthylamine are described. *Thio-p-tolyl- β -naphthylamine* was obtained as a greenish-yellow powder, m. p. 182°. F. M. G. M.

Action of Magnesium Alkyl Halides on Anilides and their Chlorides. MAX BUSCH and MARTIN FLEISCHMANN (*Ber.*, 1910, 43, 2553—2556).—Beis has shown that the interaction of acid amides

and magnesium alkyl halides leads to the formation of ketones and ammonia (Abstr., 1904, i, 15). When the aminic hydrogen atoms are replaced by alkyl groups, the authors find that a dual reaction occurs; thus, magnesium phenyl bromide (2 mols.) and benzoyl ethylaniline in ether yield ultimately benzophenone and ethylaniline (from $\text{OMgBr} \cdot \text{CPh}_2 \cdot \text{NEtPh}$), and also triphenylmethyl ethylaniline, $\text{CPh}_3 \cdot \text{NEtPh}$,

m. p. 92° (from $\text{OMgBr} \cdot \text{CPh}_3 \cdot \text{NEtPh}$ and PhMgBr), which easily decomposes in alcoholic solution into triphenylcarbinol and ethylaniline.

Magnesium alkyl halides react with imino-chlorides generally either at the double linking or at the reactive halogen atom, yielding the same product in both cases, but sometimes at both of these points of attack. Thus benzanilideimino-chloride and ethereal magnesium methyl iodide yield ultimately acetophenoneanil, $\text{NPh} \cdot \text{CPhMe}$, which cannot be isolated, but the presence of which is proved by hydrolysis with hydrochloric acid, whereby acetophenone and aniline are obtained. In a similar way the imino-chloride reacts with magnesium ethyl bromide to form ultimately an anil which yields aniline and phenyl ethyl ketone by hydrolysis, and with magnesium phenyl bromide to form ultimately benzophenoneanil, m. p. $113-114^\circ$; once in the latter preparation a considerable amount of triphenylmethyl aniline, $\text{CPh}_3 \cdot \text{NHPh}$, was obtained, but the conditions of its formation could not be repeated.

C. S.

Metathetical Reactions: Ether-thiocarbamides and their Relation to ψ -Ammonium Bases. TREAT B. JOHNSON and HERBERT H. GUEST (*J. Amer. Chem. Soc.*, 1910, 32, 1279-1285).—Cyclic quaternary bases (pyridines, quinolines, isoquinolines, and acridines) undergo isomeric change in aqueous solution, the hydroxyl group of the base migrating from the nitrogen to a carbon atom with formation of ψ -ammonium bases. The latter compounds react with alcohols at the ordinary temperature with loss of a molecule of water and production of alcoholates or ethers. When these alcoholates are warmed with alcohols, the alkyl group of the alcoholate is replaced by that of the alcohol. The mechanism of this change has been interpreted in different ways (compare Decker, Abstr., 1900, i, 522, and Gadamer, Abstr., 1905, i, 368; 1908, i, 322). In order to throw further light on these transformations, a study has been made of some ether-thiocarbamides.

The ether-thiocarbamides, $\text{OR} \cdot \text{CH}_2 \cdot \text{NH} \cdot \text{CS} \cdot \text{NHR}'$, were obtained by the action of certain thiocarbimidomethyl ethers, $\text{RO} \cdot \text{CH}_2 \cdot \text{NCS}$, on organic bases (Johnson and Guest, Abstr., 1909, i, 371). These substances are closely related to the cyclic alcoholates, as they contain the same complex, $\text{C} \cdot \text{N} \cdot \text{CH} \cdot \text{OR}$, and hence may be regarded as acyclic ψ -ammonium compounds. The ether-thiocarbamides would therefore be expected to undergo transformations with alcohols analogous to those which take place with the cyclic alcoholates, and such has been found to be the case. All the ether-thiocarbamides which have been examined react with alcohols on warming, with transposition of the alkyl groups. These reactions are reversible, and are not affected by

the b. p.'s of the alcohols or by the size of the alkyl groups involved. It is therefore possible to obtain a whole series of ether-thiocarbamides from one thiocarbimidomethyl ether. These transformations are most easily explained by assuming that unstable additive compounds are first formed, and that these decomposes with production of a new thiocarbamide and alcohol.

s-Phenylmethoxymethylthiocarbamide, $\text{NHPh}\cdot\text{CS}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{OMe}$, m. p. 133°, obtained by recrystallising *s*-phenylethoxymethylthiocarbamide or *s*-phenylisocamylloxymethylthiocarbamide from methyl alcohol, forms prismatic crystals. *s*-p-Tolylmethoxymethylthiocarbamide,

m. p. 129°, is obtained by the action of methyl alcohol on the corresponding ethoxy-compound.

E. G.

Replacement of Halogen by the Nitro-group. II. L. CHAS. RAIFORD and FREDERICK W. HEYL (*Amer. Chem. J.*, 1910, 44, 209—219).—It has been found previously (this vol., i, 373) that when 2:4:6-tribromophenol is treated with nitrous acid, a mixture of 4:6-dibromo-2-nitrophenol and 2:6-dibromo-4-nitrophenol is produced, but that 2:4:6-trichlorophenol is not affected by nitrous acid. In view of these results, it was considered of interest to study the behaviour of 2:4:6-tri-iodophenol. The work has also been extended to 2:4:6-tribromoresorcinol.

2:4:6-Tri-iodophenol has m. p. 158°, instead of 156°, as stated by Messinger and Vortmann (*Ahstr.*, 1889, 1150). The *acetate*, m. p. 154°, forms colourless needles. When sodium nitrite is added gradually to a solution of 2:4:6-tri-iodophenol in a mixture of glacial acetic acid and benzene at 12—15°, 4:6-di-iodo-2-nitrophenol is obtained, together with 2:6-di-iodo-4-nitrophenol, m. p. 155°, which forms nearly colourless prisms. It is probable that a small quantity of an iododinitrophenol is also produced in this reaction. On reducing 4:6-di-iodo-2-nitrophenol with stannous chloride in presence of hydrochloric acid, the *hydrochloride* of 4:6-di-iodo-2-aminophenol is obtained, which crystallises in long prisms.

When a solution of 2:4:6-tribromoresorcinol in glacial acetic acid is treated with sodium nitrite at 12—15°, 2:6-dibromo-4-nitroresorcinol, m. p. 143°, is produced, which forms maroon prisms or orange needles; its *ammonium* salt crystallises in deep yellow prisms. On reducing this nitro-compound with a solution of stannous chloride in hydrochloric acid, the *hydrochloride* of 2:6-dibromo-4-aminoresorcinol is obtained. 2:6-Dibromo-4-aminoresorcinol darkens above 135°, and decomposes above 175° without melting; it crystallises in prisms which are at first colourless, but soon become grey; the *picrate* begins to decompose at 220° without melting. 2:6-Dibromo-4-acetylaminoresorcinyl *diacetate*, m. p. 174—175°, forms colourless, hexagonal plates.

E. G.

Preparation of *o*- and *p*-Nitrophenols. R. S. HART (*J. Amer. Chem. Soc.*, 1910, 32, 1105—1106).—Phenol (50 grams) dissolved in alcohol (5 grams) is added drop by drop (30 drops a minute) to a solution of sodium nitrate (80 grams) in sulphuric acid (100 grams) diluted with 200 c.c. of water at 25°. The mixture is stirred vigorously

during the addition, and for half an hour afterwards. After an hour and a-half, the liquid is treated in the usual way, and gives a yield of 30 grams of *o*-nitrophenol and 13 grams of *p*-nitrophenol. W. O. W.

Phenyl Ether and Some of its Derivatives. ALFRED N. COOK (*J. Amer. Chem. Soc.*, 1910, 32, 1285—1294).—The ethers used in this investigation were prepared by distilling the aluminium derivatives of the corresponding phenols. Good yields were obtained of phenyl and *m*-tolyl ethers, but only small yields of *o*- and *p*-tolyl ethers. On rapidly distilling aluminium *p*-tolyl oxide, flashes appeared on the surface of the liquid. When some aluminium *p*-tolyl oxide which had been exposed to the air for about two months was distilled, *p*-cresol was obtained, but very little *p*-tolyl ether. The causes of these phenomena are being investigated.

Tetrabromophenyl ether, $\text{O}(\text{C}_6\text{H}_3\text{Br}_2)_2$, h. p. 280—290°/25 mm., 410—425°/760 mm., m. p. 83—84°, prepared by slowly adding an excess of bromine to a solution of phenyl ether in carbon disulphide containing a little iodine to serve as a carrier, forms large needles. It was not found possible to obtain a more highly brominated derivative.

*Dibromo-*m*-tolyl ether*, $\text{O}(\text{C}_6\text{H}_3\text{MeBr})_2$, h. p. about 250°/15 mm. and 340—350° (uncorr.)/760 mm., m. p. 43°, prepared by slowly adding the calculated quantity of bromine to a solution of *m*-tolyl ether in carbon disulphide, forms white crystals. *Tetrabromo-*m*-tolyl ether*, $\text{O}(\text{C}_6\text{H}_3\text{MeBr}_2)_2$, h. p. 260—270°/35 mm., is obtained by the action of an excess of bromine on *m*-tolyl ether in presence of a little iodine as a viscous substance which slowly crystallises. A more highly brominated derivative could not be obtained.

*2:4-Dinitrophenyl *p*-tolyl ether*, $\text{C}_6\text{H}_4\text{Me}\cdot\text{O}\cdot\text{C}_6\text{H}_3(\text{NO}_2)_2$, m. p. 93°, prepared by the action of potassium *p*-tolyl oxide on 1-bromo-2:4-dinitrobenzene, forms yellow crystals. The *sulphonic acid*,

$\text{SO}_3\text{H}\cdot\text{C}_6\text{H}_3\text{Me}\cdot\text{O}\cdot\text{C}_6\text{H}_3(\text{NO}_2)_2$, m. p. 150° (decomp.), crystallises in slender needles containing $1\frac{1}{2}\text{H}_2\text{O}$; its *barium* and *sodium* salts are described. When a solution of 2:4-dinitrophenyl *p*-tolyl ether in glacial acetic acid is warmed with chromic anhydride, it is converted into *p*-2:4-dinitrophenoxycarboxylic acid, $\text{CO}_2\text{H}\cdot\text{C}_6\text{H}_3\text{Me}\cdot\text{O}\cdot\text{C}_6\text{H}_3(\text{NO}_2)_2$, a yellow substance which does not melt below 200°; its *silver* salt is described.

2:4-Dinitrophenyl ether, $\text{C}_6\text{H}_3\cdot\text{O}\cdot\text{C}_6\text{H}_3(\text{NO}_2)_2$, m. p. 70°, h. p. 230—250°/27 mm., obtained by the action of potassium phenoxide on 1-bromo-2:4-dinitrobenzene, is a crystalline substance with a faint odour and a pungent taste. The *sulphonic acid*, $\text{SO}_3\text{H}\cdot\text{C}_6\text{H}_3\cdot\text{O}\cdot\text{C}_6\text{H}_3(\text{NO}_2)_2$, forms white, pearly flakes; its *barium* salt is described. *Trinitrophenyl ether*, $\text{C}_6\text{H}_2\text{O}(\text{NO}_2)_3$, prepared by dissolving 2:4-dinitrophenyl ether in concentrated nitric acid, crystallises in clusters of yellow prisms.

A bibliography of phenyl ether and its derivatives is appended.

E. G.

Organic Compounds of Quadrivalent Tellurium. CHARLES LEDERER (*Compt. rend.*, 1910, 151, 611—612).—Tellurium tetrachloride (1 mol.) reacts with magnesium phenyl bromide (5 mols.) in

dry ether. In addition to chlorobenzene, diphenyl, and diphenyl telluride, the product yields a sparingly soluble material when treated with a limited amount of water. On treatment with aqueous potassium iodide this furnishes *diphenyltellurium diiodide*, decomposing at 236—237°, and *triphenyltelluronium iodide*, TePh_3I . The latter crystallises in colourless needles, m. p. 247—248°, and on treatment with silver chloride or bromide gives the corresponding *chloride*, m. p. 244—245° (decomp.), and *bromide*, m. p. 259—260°.

Fixation of hydrogen chloride by diphenyltellurium leads to the formation of the *compound*, TeHPh_2Cl , m. p. 233—234°. W. O. W.

Preparation of Neutral Phenolic Esters of Diglycollic Acid. C. F. BOEHRINGER & SÖHNE (D.R.-P. 223305).—The phenyl esters of diglycollic acid are readily prepared by treating the acid dichloride with the required phenol or sodium phenoxide (substituted or otherwise) in the presence of an indifferent base, such as dimethylaniline.

Diphenyl diglycollate, $\text{O}(\text{CH}_2\cdot\text{CO}_2\text{Ph})_2$, forms colourless needles, m. p. 80°.

Disalicyl diglycollate forms colourless crystals, m. p. 173°; the α -*naphthyl* ester, colourless leaflets, m. p. 136°; the β -*naphthyl* ester, a colourless, crystalline powder, m. p. 160°; the *guaiacol* ester, colourless needles, m. p. 82°; the *o*-*tolyl* ester, needles, m. p. 101°; the *m*-*tolyl* ester, needles, m. p. 63°; the *p*-*tolyl* ester, needles, m. p. 89°; the *o*-*chlorophenyl* ester, needles, m. p. 129°; the *p*-*chlorophenyl* ester, slender needles, m. p. 130°; the *o*-*nitrophenyl* ester, colourless leaflets, m. p. 164°, and the *p*-*nitrophenyl* ester, a colourless, crystalline powder, m. p. 131°.

The solubility of these compounds in numerous solvents is fully described in the patent. F. M. G. M.

[Simple Formation of Benzyl Ethers.] JULIUS VON BRAUN (*Ber.*, 1910, 43, 2594).—Reply to Halban (this vol., i, 619). C. S.

The Addition of Bromine to Unsaturated Compounds. I. Allyl and Propenyl Derivatives of Benzene. GINO ARATI (*Gazzetta*, 1910, 40, ii, 89—94. Compare Abstr., 1909, i, 104).—A comparison of the velocity of addition of bromine in chloroform solution to chavicol and anethole, eugenol and *isoeugenol* and their methyl derivatives, safrole and *isosafrole*, myristicin and *isomyristicin*, and apiole and *isopiole*, show that the velocity is always greater in the case of the propenyl derivative.

The molecular refractive indices of myristicin and *isomyristicin* have also been measured, and are found to be M_d 89.44 and M_d 92.94 respectively. C. H. D.

The Xylenol from Dehydracetic Acid. EMILIO CARLINPANTI and A. GERMAIN (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 234—236).—The xynol produced when dehydracetic acid is distilled with calcium oxide is not *o*-4-xylenol, as stated by Tivoli (Abstr., 1891, 1455), but the 1:3:5-compound. The mistake is due to the fact that a substance is also formed which gives a reaction

with ferric chloride similar to that of *o*-4-xyleneol, and this impurity can only be removed by repeated crystallisation. When calcium acetate is heated with calcium oxide, a yellow oil, b. p. 215–225°, is obtained, which has no phenolic properties, but gives an intense coloration with ferric chloride. To explain the formation of *m*-5-xyleneol, the following mechanism is suggested. Dehydracetic acid under the conditions of the experiment yields acetyltriacetic acid, which loses carbon dioxide and is converted into diacetylacetone, which decomposes into acetic acid and acetylacetone; this then condenses with the acetone formed from the calcium acetate. In confirmation of this view, the authors find that *m*-5-xyleneol is produced when a mixture of the vapours of these two substances is led over calcium oxide at 400°.

5-Hydroxy-*m*-xyl phenylcarbamate. $C_8H_9O \cdot CO \cdot NHPh$, crystallises in shining needles, m. p. 148–149°. R. V. S.

Fluorenyl Ethers. ALFRED KLIEGEL (*Ber.*, 1910, 43, 2488–2496. Compare Abstr., 1905, i, 187).—Schmidt and Stützel (this vol., i, 29) on reducing fluorenoneoxime by tin and hot concentrated hydrochloric acid obtained fluoronyl ether, possessing a red colour, and quite different from the fluorenyl ether obtained by Barbier from fluorenyl alcohol. This red compound, the colour of which was attributed to the accumulation of benzene nuclei, is not in agreement with Witt's theory of colour.

By the action of silver oxide on 9-chlorofluorene, fluorenyl ether was obtained in colourless, lustrous plates, m. p. 238°, and it is further shown that the red compound of Schmidt and Stützel is in reality diphenylene-phenanthrene, m. p. 257°, coloured red by admixture with di-biphenylene ethylene, m. p. 187°.

The first product of the action of hydrochloric acid and tin, or, better, of stannous chloride, is a glistening, red, crystalline compound, which is a stannichloride of 9-iminofluorene, $\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix} > C:NH$. The picrate crystallises in lustrous, orange needles, and when decomposed with ammonia yields the crystalline base, which separates in pale straw-yellow, slender needles, m. p. 124°. On warming with water, it readily decomposes into ammonia and ketone. An egg-yellow and an orange oxalate and a similarly coloured sulphate were also isolated. The acetate crystallises in citron-yellow needles, m. p. 104°. E. F. A.

[*m*-Hydroxyphenyl Mercaptan.]. LADISLAUS VON SZATHMÁRY (*Ber.*, 1910, 43, 2485–2487).—Sodium *m*-benzenedisulphonate was converted into sodium *m*-phenolsulphonate, and this into the sulphonyl chloride, which was obtained as a viscid, oily, brown product having a pungent, disagreeable odour. It is reduced by tin and hydrochloric acid to *m*-hydroxyphenyl mercaptan. This crystallises when strongly cooled, but is oily at the ordinary temperature. It has a pungent, unpleasant odour, and with lead acetate yields an insoluble, stable, yellow precipitate of the lead salt, $Pb(S \cdot C_6H_4 \cdot OH)_2$. It shows no coloration with either sulphuric acid or sodium hydroxide. E. F. A.

Symmetrical Trithiophenols. JACQUES POLLAK and R. TUCKAHOVIĆ (*Monatsh.*, 1910, 31, 695—707).—*Trithiomethylphloroglucinol* [*toluene*: 2:4:6-*trithiol*], $C_6H_2Me(SH)_3$, prepared by reducing *o*-tolyl-2:4:6-trisulphonyl chloride with tin and hydrochloric acid, forms white needles, m. p. 49—53°, having a characteristic odour. It readily undergoes oxidation, either on exposure to the air or under the action of oxidising agents, with the formation of yellow to yellowish-red products. With lead acetate, it gives a yellow precipitate, which quickly changes to red. In glacial acetic acid solution, it is readily transformed into the original trisulphonyl chloride by the action of chlorine.

The *triacetyl* derivative, $C_6H_2Me(SAc)_3$, forms needles, m. p. 93—95°, and is readily obtained by heating with acetic anhydride and fused sodium acetate. The *trimethyl ether*, $C_{10}H_4S_3$, prepared by the action of diazomethane in ethereal solution, or of methyl iodide in alkaline alcoholic solution, forms slender needles, m. p. 61—63°; it cannot be obtained by the action of hydrogen chloride and methyl alcohol. Trithiomethylphloroglucinol consequently behaves as a non-tautomeric phenol.

The condensation product with chloroacetic acid,

has m. p. 197—200°; the *ethyl* ester, $C_6H_2Me(S \cdot CH_2 \cdot CO_2Et)_3$, has m. p. 30—35°.

The action of cold concentrated nitric acid (D 1.4) on the trimethyl ether gives rise to the *mononitro*-derivative, $NO_2 \cdot C_6HMe(SMe)_3$, yellow prisms, m. p. 84—87°. With hot concentrated nitric acid or cold fuming nitric acid, a *monosulphoxide* of the above-mentioned nitro-derivative is produced, $NO_2 \cdot C_6HMe \cdot (SMe)_2 \cdot SOMe$, which forms slender, yellow needles, m. p. 178.5—179.5°. The position of the sulphoxide group has not been ascertained. Hot fuming nitric acid also gives rise to a substance, m. p. 235—237°, which requires further investigation.

Trithiophloroglucinol (*Abstr.*, 1909, i, 761) has now been obtained in the form of white needles, m. p. 57—60°. The product,

obtained with chloroacetic acid forms white, silky needles, m. p. 179—180°, from which the *ethyl* ester was obtained as an oil. The trimethyl ether gives the *mononitro*-derivative, $NO_2 \cdot C_6H_2(SMe)_3$, with cold concentrated nitric acid; it forms dark yellow, slender needles, m. p. 148—150°.

T. S. P.

Cholesterol. II. LEO TSCHUGAEFF and W. FOMIN (*Annalen*, 1910, 375, 288—297. Compare this vol., i, 31, 479).—In addition to work already recorded, the paper contains the following results. *Ethyl cholesterylzanthate*, $C_{27}H_{45}O \cdot CS \cdot SEt$, m. p. 141.5°, and the *propyl* ester, m. p. 135°, have almost the same dispersion coefficient as the methyl ester. *Cholesterylzanthamide*, $C_{27}H_{45}O \cdot CS \cdot NH_2$, m. p. 227°, is obtained by digesting the methyl ester with about 10% alcoholic ammonia for many days.

The constitutions of α -cholesterylene, cholesterol, β -cholesterylene,

and cholestane are represented respectively by: $R \begin{smallmatrix} \text{CH} \\ \text{CH}_2 \end{smallmatrix} \text{CH}$,
 $R \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix} \text{CH} \cdot \text{OH}$, $R \begin{smallmatrix} \text{CH}_2 \\ \text{CH} \end{smallmatrix} \text{CH}$, and $R \begin{smallmatrix} \text{CH}_2 \\ \text{CH}_2 \end{smallmatrix} \text{CH}_2$, where R is
 $(\text{H}_2\text{Pr}^{\beta} \cdot \text{CH}_2)_{17} \text{C}_{17} \text{H}_{35}$

C. S.

Aromatic Fluorine Derivatives and Estimation of Fluorine in the Same. HANS MEYER and ALFRED HUB (*Monatsh.*, 1910, 31, 933—938).—The three fluorobenzoic acids can be prepared readily by the oxidation of the fluorotoluenes with permanganate (compare Hollemann, Abstr., 1905, i, 425). The *o*-acid has m. p. 122°. The corresponding fluorobenzoyl chlorides, $\text{C}_6\text{H}_4\text{F} \cdot \text{COCl}$, can be obtained by the action of thionyl chloride on the acids. They are colourless, strongly refractive liquids with an odour resembling that of benzoyl chloride. The *o*-compound has b. p. 204° and m. p. 4°; the *m*-compound, b. p. 189° and m. p. -30°, and the *p*-compound, b. p. 191—192° and m. p. 9°.

The methyl esters, $\text{C}_6\text{H}_4\text{F} \cdot \text{CO}_2\text{Me}$, have boiling points and melting points as follows: *ortho*, 207°, -20°; *meta*, 194—195°, -10°, and *para*, 197°, 4.5°. Some of these compounds have lower b. p.'s than the unsubstituted derivatives.

o-Fluorobenzamide, $\text{C}_6\text{H}_4\text{F} \cdot \text{CO} \cdot \text{NH}_2$, crystallises from water in colourless needles, m. p. 114°; the *meta*-compound in colourless plates, m. p. 128—129°, and the *para*-compound in colourless needles, m. p. 155°.

In estimating the fluorine in these compounds, the substance is heated with lime in a nickel tube, 40 cm. long and 4—5 mm. diameter, the end of which is closed by means of silver solder. The tube is treated in much the same manner as in the estimation of halogens by the lime method; it is necessary, however, to see that the lime is completely soluble in dilute acetic acid, and a temperature of 1000° must be attained in all parts of the tube. At the end the calcium fluoride is estimated in the usual manner.

J. J. S.

Condensation Products of Anthranilic Acid with Aromatic Aldehydes. HUCC WOLF (*Monatsh.*, 1910, 31, 903—916).—Various aromatic aldehydes have been condensed with anthranilic acid in alcoholic solution in order to determine whether the resulting Schiff's bases exist in stereoisomeric forms (compare Hantzsch and Schwab, Abstr., 1901, i, 378; Anselmino, *ibid.*, 1907, i, 913; Manchot and Furlong, *ibid.*, 1909, i, 805; this vol., i, 33).

Two isomeric forms were observed in the anils obtained by the condensation of the acid with *o*- and *p*-hydroxybenzaldehydes.

Benzylideneanthranilic acid, $\text{CHPh} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$, crystallises in sulphur-yellow needles, m. p. 128°; *p*-tolylideneanthranilic acid, $\text{C}_6\text{H}_4\text{Me} \cdot \text{CH} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$, forms lemon-yellow, rectangular plates, m. p. 154°; *o*-nitrobenzylideneanthranilic acid,

$\text{NO}_2 \cdot \text{C}_6\text{H}_3 \cdot \text{CH} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$, crystallises in yellow needles, m. p. 172°, and readily turns red on

exposure to the air; the isomeric *para*-compound forms pale yellow plates, m. p. 162°, and the *meta*-derivative, pale yellow needles, m. p. 206°.

Salicylideneanthranilic acid, $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$, separates as small, yellow plates, m. p. 193°, when its alcoholic solution is cooled rapidly, otherwise the red modification, which crystallises in stout prisms, m. p. 200°, is obtained. The yellow crystals are transformed into the red when dissolved in amyl alcohol and the solution cooled slowly, or when the solution is cooled quickly and the yellow crystals left in contact with the amyl alcohol mother liquor for several hours. *p*-Hydroxybenzylideneanthranilic acid exists in yellow and red modifications, of which the red is the less stable. The yellow form is more readily soluble in ether than the red, and has m. p. 224°. The isomeric *m*-hydroxy-derivative crystallises in yellow prisms, m. p. 182°.

o-Methoxybenzylideneanthranilic acid, $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$, forms yellow needles, m. p. 128°; the isomeric *para*-compound crystallises in yellow, rectangular plates, m. p. 142°, which turn red on exposure to the air. *Dimethylaminobenzylideneanthranilic acid*,

forms brick-red prisms, m. p. 214°.

3:4-Dihydroxybenzylideneanthranilic acid,

crystallises in glistening, red needles, m. p. 226° (decomp.). 4-Hydroxy-3-methoxybenzylideneanthranilic acid,

forms slender, lemon-yellow needles, m. p. 164°. 3:4-Piperonylideneanthranilic acid, $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_3\cdot\text{CH}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$, forms pale yellow, rectangular plates, m. p. 188°. *Cinnamylideneanthranilic acid*, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$, crystallises from toluene or ethyl acetate in yellow prisms, m. p. 156°. When heated at 100°, it begins to turn red, and gives an odour of cinnamaldehyde.

When alcoholic solutions of these anil acids are heated with the equivalent amount of phenylhydrazine for about thirty minutes on the water-bath, the $\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ group is replaced by the

group, and the phenylhydrazones of the aldehydes are obtained.

J. J. S.

Lactonoid Anhydrides of Acylated Amino acids. V. **Lactone of *r*-Benzoylphenylalanine.** ERNST MOHR and Fu. SROSCHER (*J. pr. Chem.*, 1910, [ii], 82, 322—335. Compare this vol., i, 483, 557).—Much of the work has been recorded (Abstr., 1909, i, 581). The ethyl ester, chloride, and anilide of benzoylphenylalanine (Max, Abstr., 1909, i, 926) are conveniently prepared from the lactone; also the anilide, $\text{CH}_2\text{Ph}\cdot\text{CH}(\text{NH}\cdot\text{Bz})\cdot\text{CO}\cdot\text{NHPh}$, m. p. 233—234°, from the lactone and aniline in dry ether. *Benzoylphenylalanylglycine*, $\text{CH}_2\text{Ph}\cdot\text{CH}(\text{NH}\cdot\text{Bz})\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, m. p. 240—242° (decomp., softening at 185°), is obtained from glycine and the lactone of benzoylphenylalanine at 130°, or, better, in aqueous acetone in the presence of sodium hydroxide.

C. S.

o-Aminobenzyl Cyanide [*o*-Aminophenylacetonitrile] and its Conversion into 2-Aminoindole and Indole. ROBERT PSCHORR and GERN. HOPFF (*Ber.*, 1910, 43, 2543—2552).—The conversion of *o*-aminocinnamonnitrile into 2-aminoquinoline by acids or alkalis (P-schorr, *Abstr.*, 1898, i, 491) induced the authors to examine the behaviour of *o*-aminophenylacetonitrile under similar conditions. This substance is conveniently prepared by converting *o*-nitrophenylacetic acid by a suspension of phosphorus pentachloride in ether into the chloride, a solution of which in benzene and ether is converted by ammonia into *o*-nitrophenylacetamide, m. p. 160°; the amide is converted by thionyl chloride into the nitrile, an alcoholic solution of which is reduced by stannous chloride and concentrated hydrochloric acid to *o*-aminophenylacetonitrile, m. p. 72°, which is best isolated by treating an aqueous solution of its stannichloride with 30% sodium hydroxide, whereby the substance separates in almost quantitative yield. The presence of the "activated" methylene group in the ortho-position to the amino group renders derivatives of the substance very liable to intramolecular condensation. Thus a solution of *o*-aminophenylacetonitrile in *N*-hydrochloric acid is converted into *indole-3-carboxylonitrile*, $C_6H_4 \begin{smallmatrix} \text{C(CN)} \\ \text{N} \end{smallmatrix} \text{NH}$, m. p. 140°, whilst a solu-

tion in ether yields by treatment with sodium and amyl formate, *indole-3-carboxylonitrile*, m. p. 178°. This nitrile forms an *acetyl* derivative, m. p. 202°, which is also obtained when *indole-3-alloxime*, m. p. 197—200°, is heated with acetic anhydride.

o-Aminophenylacetonitrile yields a *formyl* derivative,

m. p. 110°, which shows no tendency to intramolecular condensation, and is simultaneously hydrolysed and converted into 2-aminoindole by boiling potassium carbonate; an *acetyl* derivative, m. p. 120°, and a *diacetyl* derivative, m. p. 80°.

By treatment with boiling alcoholic sodium ethoxide in an atmosphere of hydrogen, *o*-aminophenylacetonitrile is converted into 2-aminoindole, $C_6H_4 \begin{smallmatrix} \text{CH} \\ \text{NH} \end{smallmatrix} \text{C} \cdot NH_2$, which separates from water in

prisms containing H_2O , has a strongly alkaline reaction, is reduced by sodium and alcohol to indole, and forms a *diacetyl* derivative, m. p. 142°, which is converted by aqueous potassium carbonate into 2-*acetyl*-aminoindole, m. p. 167°. When an ethereal solution of 2-aminoindole is treated with ethyl chloroformate, three products are obtained, two of which, m. p. 93° and 160° respectively, are isomeric and contain two carbethoxy-groups, whilst the third has m. p. 145—150° and contains only one carbethoxy-group. The constitution of 2-aminoindole is proved by the fact that Piccini and Salmoni's indole-2-urethane, by treatment with ethyl chloroformate, yields the isomeride, m. p. 93°, containing two carbethoxy-groups, mentioned above. C. S.

Action of Thionyl Chloride on Benzoic Acid. ROBERT STOLLÉ (*Ber.*, 1910, 43, 2471—2473).—By the interaction of thionyl chloride and benzoic acid in carbon tetrachloride solution at the ordinary temperature, α -chlorodiphenylacetic acid is formed. When the con-

stituents are boiled some days in the same solvent, *α-chlorodiphenylacetic anhydride*, $(C_6H_5Cl-CO)_2O$, is formed, m. p. 129°. This compound also arises when *α-chlorodiphenylacetic acid* is warmed with thionyl chloride. With aniline in ethereal solution, *α-anilindiphenylacetic acid*, m. p. 168°, and *α-anilindiphenylacetic anhydride*, crystallising in minute needles, m. p. 181°, and insoluble in sodium hydroxide, are formed.

A by-product of the action of thionyl chloride on benzoic acid crystallises in compact crystals insoluble in sodium carbonate, m. p. 119°. This is possibly *tetraphenyldiglycolyl chloride*, $C_{28}H_{20}O_2Cl_2$; it forms an anilide, m. p. 134°.

On shaking chlorodiphenylacetic anhydride in ether with sodium carbonate, an amorphous compound, probably benzoic anhydride, m. p. about 90°, is obtained. When heated with yellow mercuric oxide, chlorodiphenylacetic anhydride yields benzilide, m. p. 194°, which probably has the constitution of tetraphenyldiglycolic anhydride.

E. F. A.

Action of Dichloroacetic Acid on Aniline and its Homologues. III. GUSTAV HELLER with SALO ASCHKENASI (*Annalen*, 1910, 375, 261—288. Compare Abstr., 1908, i, 216).—The paper contains a repetition of some of the earlier work in order to controvert Ostromisslensky's views of the course of the reaction between dichloroacetic acid and aniline or its homologues (Abstr., 1908, i, 82, 888, 889).

The reaction between dichloroacetic acid and *p*-anisidine furnishes the only case in which the initial product of the reaction has been isolated; *di-p-anisidinoacetic acid*, $CO_2H \cdot CH(NH \cdot C_6H_4 \cdot OMe)_2$, m. p. 201—202°, forms a *hydrochloride*, $C_{16}H_{18}O_2N_2 \cdot HCl$, m. p. about 215°, cannot be diazotised or benzoylated, and does not form a nitrosoamine. The product of the reaction between dichloroacetic acid and *o*-toluidine is not *o*-methylaminophenyl-*o*-toluidinoacetic acid (Ostromisslensky, *loc. cit.*), but 2:2'-*diaminoditolyl-4:4'-acetic acid*,

since it requires 2 mols. of sodium nitrite for diazotisation, and the diazotised product yields *bis-β-naphtholazodi-o-tolylacetic acid*,

m. p. 195°, *bis-6-sulpho-β-naphtholazodi-o-tolylacetic acid*,

and *bis-3:6-disulpho-β-naphtholazodi-o-tolylacetic acid*,

with *β*-naphthol, *β*-naphthol-6-sulphonic acid, and *β*-naphthol-3:6-disulphonic acid respectively. 2:2'-Diaminoditolyl-4:4'-acetic acid yields only a *monobenzoyl* derivative, m. p. 242—243°, by the Schotten-Baumann method; when benzoylated in the presence of sodium hydrogen carbonate, it yields a mixture of the preceding compound and an anhydro-derivative, $C_{23}H_{20}O_2N_2$, thereof.

2:2'-*Diamino-di-m-xylyl-4:4'-acetic acid*,

m. p. 241°, obtained from aqueous potassium dichloroacetate, sodium acetate, and *m*-2-xylydine on the water-bath, or from an acetic acid solution of the base and glyoxylic acid at the ordinary temperature,

forms a *dibenzoyl* derivative, $C_{22}H_{20}O_4N_2$, m. p. 272° (decomp.), with benzoyl chloride in aqueous potassium hydroxide, an *anhydrobenzoyl* derivative, $C_{25}H_{24}O_2N_2$, unchanged at 300° , with benzoyl chloride in cold pyridine, and combines, after being diazotised, with β -naphthol-6-sulphonic acid in sodium carbonate solution to form a normal *bisazo*-compound, $C_{28}H_{28}O_{10}N_4S_2$, the combination in a solution of an alkali hydroxide yielding a black substance.

The usual reaction between dichloroacetic acid and ψ -cumidine yields 3- ψ -cumidino-4:5:7-trimethyloxindole,

decomp. 205° ; this is oxidised by iodine in glacial acetic acid to 4:5:7-trimethylisatin, $C_6HMe_3 \begin{array}{c} \text{CO} \\ \text{NH} \end{array} \text{CO}$, m. p. 276° , which forms red needles, yields a *phenylhydrazone*, m. p. 248° , and is so stable to alkalis that the pyrrole nucleus is only ruptured at 50° .

The product of the direct action of dichloroacetic acid on aniline is not 4:4'-diaminodiphenylacetic acid (Ostrowskislensky, *loc. cit.*), but its hydrochloride (Heller, Abstr., 1909, i, 20); the free acid has m. p. 195° , forms a *diacetyl* compound, m. p. 231° , and yields a *dibenzoyl* derivative, decomp. 256° , with benzoyl chloride and sodium hydroxide, and an *anhydrobenzoyl* derivative, $C_{21}H_{16}O_2N_2$, softening at 225° , with benzoyl chloride in cold pyridine. The product obtained by the addition of a dilute acetic acid solution of aniline to aqueous glyoxylic acid is aniline anilglyoxylate, not dianilinoacetic acid (Ostrowskislensky, Abstr., 1908, i, 889), because only 1 mol. of aniline is eliminated by cold sodium carbonate.

C. S.

Preparation of Oxyaryluurethane Carbamido- and Thio-carbamido-cinnamic Acid Esters. GESELLSCHAFT FÜR CHEMISCHE INDUSTRIE IN BASEL (D.R.-P. 224107).—Cinnamic acid esters of the

general formula $C_6H_5 \cdot CH:CH \cdot CO \cdot O \cdot R \cdot NH \cdot C \begin{array}{c} X \\ \ll Y \end{array}$ (where R is an aromatic radicle, X oxygen or sulphur, Y an alkyloxy, amino, or alkyl-amino-group) are readily prepared when cinnamoyl chloride is heated with *p*-hydroxyphenyl-carbamide or urethanes; they are of great value in the treatment of tubercular complaints, and in surgery.

p-Cinnamoyloxyphenylcarbamide, colourless needles, m. p. 203° , is prepared by heating (or allowing to remain at the ordinary temperature) cinnamoyl chloride with *p*-hydroxyphenylcarbamide in aqueous alkaline solution.

m-Cinnamoyloxyphenylcarbamide has m. p. $204-205^\circ$.

p-Cinnamoyloxyphenylurethane, colourless needles, m. p. $150-151^\circ$, is prepared from the foregoing acid chloride and *p*-hydroxyphenylurethane, $OH \cdot C_6H_4 \cdot NH \cdot CO_2Et$. *o*-Cinnamoyloxyphenylurethane has m. p. $101-102^\circ$.

p-Cinnamoyloxyphenylallylcarbamide,

m. p. $129-130^\circ$, is prepared in analogous manner from *p*-hydroxyphenylallylthiocarbamide in acetone solution.

Cinnamic anhydride, or the acid in the presence of phosphoryl

chloride, can also be employed for this condensation, likewise other hydroxyphenylcarbamido-derivatives. F. M. G. M.

Melting Point of Granules of Salol. P. N. PAWLOFF (*Zeitsch. physikal. Chem.*, 1910, 74, 562—566. Compare Abstr., 1908, ii, 927).—The relationship between the melting point of salol particles and their magnitude has been further investigated by heating commercial salol for long periods at constant temperatures, and determining by microscopic observation the surface area of the largest crystals which formed as a result of fusion and subsequent crystallisation. It was found necessary to heat for about two and a-half hours in order to obtain the maximum size of crystals.

The more fusible portion was investigated between 34·8° and 37·8° by the method described. The maximum crystal at 37·8° had a surface of 1296 sq. μ ; the maximum formed at 34·8° a surface of 228 sq. μ . The less fusible portion was investigated between 39° and 41°. At the former temperature, particles of surface 200 sq. μ , at the latter temperature, particles of surface 1328 sq. μ , remain unaltered. The relative size of the crystals cannot readily be determined, but from the data obtained for the less fusible portion it is estimated that when the specific surface is increased one hundred times by dividing up the particles, the melting point is lowered by 2·8°. G. S.

Preparation of Monoiodosalicylic Acids or its Nuclear Homologues. MAX HAASE (D.R.-P. 224536. Compare Lassar-Cohn and Fritz Schultze, Abstr., 1905, i, 893).—The methods that have previously been employed for the preparation of monoiodosalicylic acids have given poor yields and impure products; the one now described is that whereby an alkaline solution of sodium salicylate is slowly treated with a very slight excess of iodine dissolved in potassium iodide at the ordinary temperature and with continual stirring; colourless needles, m. p. 197°, were obtained. Three iodosalicylic acids with m. p.'s 198°, 196°, and 199·5° have previously been described in the literature. F. M. G. M.

Preparation of Amides of Monoiodosalicylic Acid and its Homologues. MAX HAASE (D.R.-P. 224346).—The amides of iodosalicylic acid (or other hydroxycarboxylic acids) can be readily prepared by treating the respective acid amide with potassium iodide and iodine in alkaline solution and allowing the mixture to remain at the ordinary temperature.

Iodosalicylamide, colourless leaflets, m. p. 230—231°, is sparingly soluble in hot water, and of therapeutic value. F. M. G. M.

Preparation of 5-Iodo-2-acetoxybenzoic Acid. MAX HAASE (D.R.-P. 224537).—The attempted preparation of iodoacetoxybenzoic acid from acetoxybenzoic acid results in the elimination of the acetyl group; it is now found that acetylation of iodosalicylic acid yields the required product.

5-Iodo-2-acetoxybenzoic acid, colourless needles, m. p. 175°, is prepared by boiling iodosalicylic acid with acetic anhydride in the presence

of anhydrous sodium acetate during three hours; it is a very important therapeutic agent, comparing favourably with *o*-acetoxybenzoic acid (aspirin) in being tasteless and less readily hydrolysed.

F. M. G. M.

Preparation of Acylsalicylic [*o*-Acyloxybenzoic] Anhydrides. ALFRED EINHORN (D.R.-P. 224844).—When the carbonyl esters of acylsalicylic acids (usually oils) having the general formula $OX \cdot C_6H_4 \cdot CO \cdot O \cdot CO_2R$ ($R = \text{alkyl}$; $X = \text{acyl}$) are heated, they yield the corresponding crystalline acyl salicylic anhydride.

o-Acetoxybenzoic anhydride, glistening needles, *m. p.* 85°, is prepared by heating *o*-acetoxybenzoic acid with ethyl chlorocarbonate in benzene or ethereal solution in the presence of a tertiary base, such as pyridine; the ethyl *o*-acetoxybenzoylcarbonate, $OAc \cdot C_6H_4 \cdot CO \cdot O \cdot CO \cdot OEt$, is isolated in the form of a viscid oil, which, when heated during ten to twenty-four hours on the water-bath, is transformed into the foregoing anhydride.

Benzoxyloxybenzoic anhydride, prismatic needles, *m. p.* 109—111°, is similarly obtained from ethyl *o*-benzoxyloxybenzoylcarbonate,

o-Cinnamoyloxybenzoic acid anhydride, slender needles, *m. p.* 110—112°, from ethyl *o*-cinnamoyloxybenzoylcarbonate, *m. p.* 53—55°. These compounds are of therapeutic value.

F. M. G. M.

The *N*-Methyl Derivatives of Phenylalanine and Tyrosine. ERNST FRIEDMANN and S. GUTMANN (*Biochem. Zeitsch.*, 1910, 27, 491—497).—In connexion with earlier experiments on the behaviour of methylated amino-acids in the animal body (Friedheim, *Abstr.*, 1908, i, 205), the authors have prepared the methyl derivatives of the aromatic amino-acids occurring in proteins. *α*-Methylamino-*β*-phenylpropionic acid (phenyl-*N*-methylalanine), $CH_3Ph \cdot CH(NHMe) \cdot CO_2H$, prepared from aqueous methylamine and *α*-bromo-*β*-phenylpropionic acid, crystallises in three-sided plates subliming at 252—254° (decomp.).

p-Methoxybenzylmalonic acid, $OMe \cdot C_6H_4 \cdot CH_2 \cdot CH(CO_2H)_2$, prepared by reducing anisylidenemalonic acid with sodium amalgam by Knoevenagel's condensation, crystallises in large, irregular plates, *m. p.* 118.5° (decomp.). On treatment with bromine, it yields the *α*-bromo-derivative, $OMe \cdot C_6H_4 \cdot CH_2 \cdot CBr(CO_2H)_2$, which crystallises in four-sided leaflets decomposing at 153°. On heating at 120—130° with a little water, this gives *α*-bromo-*β*-*p*-methoxyphenylpropionic acid,

a brown, viscid oil, which with methylamine furnishes *α*-methylamino-*β*-*p*-methoxyphenylpropionic acid, crystallising in colourless scales, *m. p.* 254—257° (decomp.). This, on hydrolysis with hydrobromic acid, gives *α*-methylamino-*β*-*p*-hydroxyphenylpropionic acid (*N*-methyltyrosine), $OH \cdot C_6H_4 \cdot CH_2 \cdot CH(NHMe) \cdot CO_2H$, which crystallises in bunches of blunt needles, *m. p.* 315°.

G. S. W.

2-Naphthol-3-carboxylic Acid and its Condensation with Benzaldehyde. FRANZ FRIEDL (*Monatsh.*, 1910, 31, 917—932. Compare J. Schmid, *Abstr.*, 1893, i, 475; Möhlau, *ibid.*, 1896, i, 43).—The ketonic formula for 2-naphthol-3-carboxylic acid is some-

what analogous to that of benzyl methyl ketone; the condensation of benzaldehyde with methyl 2-naphthol-3-carboxylate in the presence of hydrogen chloride has been studied, and has been found to be of the same type as the condensation of benzyl methyl ketone and benzaldehyde in the presence of hydrogen chloride (Goldschmiedt and Krczmar, Abstr., 1901, i, 40), the resulting compound being methyl α -chloro-

1-benzyl-2-naphthol-3-carboxylate, $C_6H_5 \begin{smallmatrix} C(CHPhCl):C:OH \\ CH= \\ C:CO_2Me \end{smallmatrix}$ or the

tautomeric ketone. The halogen atom in this compound is extremely reactive, and can be replaced readily by hydroxyl, methoxy-, phenoxy-, amino-, and anilino-groups (compare Braun, this vol., i, 479).

Methyl 2-naphthol-3-carboxylate has m. p. 73°.

Methyl α -chloro-1-benzyl-2-naphthol-3-carboxylate, $C_{19}H_{15}O_3Cl$, formed when dry hydrogen chloride is passed into a solution of methyl 2-naphthol-3-carboxylate in benzaldehyde at 0°, and the saturated solution kept for twenty-four hours, crystallises from perfectly dry benzene in microscopic prisms, m. p. 160–161°. At higher temperatures it loses hydrogen chloride, and at 220–225° is completely decomposed.

The corresponding *bromo-derivative*, $C_{19}H_{15}O_3Br$, has m. p. 183°; the *hydroxy-derivative*, *methyl 1- α -hydroxybenzyl-2-naphthol-3-carboxylate*, $C_{19}H_{16}O_4$, crystallises from benzene in pale yellow, glistening prisms, m. p. 173–174°. *Methyl 1- α -acetoxybenzyl-2-naphthol-3-carboxylate*, obtained by the action of acetic anhydride on the hydroxy-compound, forms pale yellow prisms, m. p. 136–137°. *Methyl α :2-diacetoxy-1-benzyl-3-naphthoate* has m. p. 70–73°, and decomposes at 85°. *Methyl 1- α -methoxybenzyl-2-naphthol-3-carboxylate*, $C_{20}H_{18}O_4$, prepared by the action of methyl alcohol on the chloro-derivative, crystallises from a mixture of benzene and alcohol in yellow, flat prisms, m. p. 177°. The corresponding *ethoxybenzyl derivative*, $C_{21}H_{20}O_6$, has m. p. 116–117°, and the *phenoxybenzyl compound*, $C_{23}H_{20}O_6$, m. p. 188°.

Methyl 1- α -aminobenzyl-2-naphthol-3-carboxylate, $C_{19}H_{17}O_3N$, crystallises from a mixture of chloroform and alcohol in yellow, microscopic prisms, m. p. 220°; the corresponding *anilinobenzyl derivative*,

$C_{25}H_{21}O_3N$,
crystallises in small prisms, m. p. 214°, and yields a *hydrochloride*,

$C_{25}H_{21}O_3N \cdot HCl$,
in the form of colourless crystals, m. p. 175° (decomp.).

1-Benzyl 2-naphthol-3-carboxylic acid, $C_{18}H_{14}O_3$, obtained by heating the methyl ester of the chloro-acid with hydriodic acid, crystallises in lemon-yellow needles, m. p. 224°, and gives a blue coloration with ferric chloride; the *acetyl derivative*, $C_{20}H_{16}O_4$, forms colourless, glistening needles, m. p. 166°, and the *methyl ester*, $C_{19}H_{16}O_3$, microscopic, yellow needles, m. p. 107°.

Most of the compounds are probably equilibrium mixtures of the ketonic and enolic forms. J. J. S.

Condensation of Diphenyleneglycollic Acid with Phenols and Phenol Ethers. AUGUSTIN BISTRZYCKI and FRANZ VON WERRA (*Ber.*, 1910, 43, 2496–2505).—It was shown previously (Bistrzycki,

Abstr., 1901, i, 716) that benzilic acid condenses with phenols, and that the tertiary acids, formed readily on solution in concentrated sulphuric acid, lose carbon monoxide, forming carbinols. Diphenyleneglycollic acid likewise condenses with phenols, but the acids formed are only decomposed at high temperatures by concentrated sulphuric acid, and sulphonic acids of the expected carbinols are obtained.

9-*p*-Hydroxyphenylfluorene-9-carboxylic acid,

prepared by condensation of diphenyleneglycollic acid with phenol, is obtained in microscopic, colourless, obliquely-cut plates from benzene containing a molecule of the solvent; it sinters and loses this at 98°, the residue becoming solid and getting red, m. p. 177° (decomp.). The benzene is difficult to remove; a preparation from alcohol had m. p. 178° (decomp.).

A by-product of the condensation is the lactone of 9-*o*-hydroxyphenylfluorene-9-carboxylic acid, $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{O} < \begin{array}{c} \text{C}_6\text{H}_4 \\ \text{CO} \end{array} > \text{O}$, which crystallises in microscopic, doubly refractive pyramids, m. p. 213°. On heating *p*-hydroxyphenylfluorene-9-carboxylic acid in a stream of air at 200°, carbon dioxide is eliminated, and 9-*p*-hydroxyphenylfluorene is formed, crystallising in colourless needles, m. p. 178—179° (decomp.), identical with the product obtained by Bistrzycki and Vlekke (*Diss.*, 1905) from phenol and fluorenyl alcohol.

9-*p*-Acetoxyphenylfluorene, $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{CH} \cdot \text{C}_6\text{H}_4 \cdot \text{OAc}$, obtained on boiling *p*-hydroxyphenylfluorene-9-carboxylic acid with acetic anhydride, crystallises in slender needles, m. p. 139—140°.

9-*p*-Hydroxy-*m*-tolylfluorene-9-carboxylic acid, from diphenyleneglycollic acid and *o*-cresol, crystallises in matted prisms, m. p. 183—184° (decomp.). The corresponding lactone of 9-*o*-hydroxy-*m*-tolylfluorene-9-carboxylic acid separates in colourless plates, m. p. 147.5—149°.

9-*p*-Hydroxy-*m*-tolylfluorene, obtained by heating the above carboxylic acid at 220°, crystallises in colourless, six-sided prisms, m. p. 165—166° (decomp.). The acetate crystallises in rosettes of colourless prisms, m. p. 95—97°.

Diphenyleneglycollic acid condenses with *m*-cresol, forming a *p*-hydroxy-acid, which crystallises with difficulty. At the same time, 9-*o*-hydroxy-*p*(1)-tolylfluorene-9-carboxylic acid lactone is obtained; it separates in aggregates of obliquely-cut prisms, m. p. 192°. The lactone of 9-(2'-hydroxy-5'-tolyl)fluorene-9-carboxylic acid is the only product of the condensation with *p*-cresol. It is at first obtained as a red oil, and crystallises in transparent plates with many faces, m. p. 138°.

9-*p*-Methoxyphenylfluorene-9-carboxylic acid, prepared by condensation with anisole, forms a crust of colourless, microscopic plates, m. p. 144—145° (decomp.). 9-*p*-Methoxyphenylfluorene, obtained on heating the foregoing compound at 160°, forms colourless prisms, m. p. 21—22°.

E. F. A.

Synthesis of *iso*Propylisophthalic Acid and Dimethylphthalidecarboxylic Acid. GUIDO BARGELLINI (*Gazzetta*, 1910, 40, ii, 27—36).—The position assigned to the side-chain in santonin with respect to the ketonic group depends on the constitution of the dimethylphthalidecarboxylic acid obtained from it by Cannizzaro and Gucci (Abstr., 1893, i, 665). The acid has therefore been synthesised.

By nitrating cuminic acid with fuming nitric acid, 3-nitrocuminic acid (3-nitro-4-propylbenzoic acid) is obtained in prisms, m. p. 156—157°. Reduction with ammonium sulphide yields 3-aminocuminic acid, which crystallises in a labile modification, m. p. 104°, and a stable modification, m. p. 129°. Diazotisation, followed by heating with a solution of potassium copper cyanide, yields an uncrystallisable 3-cyanocuminic acid. This acid is very difficult to saponify, and it is necessary to convert it into the *amide*, $\text{CO}_2\text{H}\cdot\text{C}_6\text{H}_4\cdot\text{Pr}^2\cdot\text{CO}\cdot\text{NH}_2$, by boiling with sodium hydroxide. The product has m. p. 265°, and is converted into *iso*propylisophthalic acid by dissolving in concentrated sulphuric acid and adding sodium nitrite. The product crystallises from boiling water, and has m. p. 236°. Oxidation with potassium permanganate in alkaline solution converts it into dimethylphthalidecarboxylic acid (annexed formula), which is identical with that prepared from santonin. C. H. D.

A New Synthesis of Dimethylphthalidecarboxylic Acid. GUIDO BARGELLINI and G. FORL-FORTI (*Gazzetta*, 1910, 40, ii, 74—89. Compare preceding abstract).—An attempt has been made to prepare the acid (II) for comparison with the acid obtained from santonin, which is assumed to have the constitution (I). The method

selected was that of converting 3-nitrophthalic anhydride into the dimethylphthalide, and then of replacing the nitro-group by carboxyl. It is found, however, that the neighbourhood of the nitro-group prevents the anhydride from reacting with Grignard's reagent.

When dimethylphthalide is nitrated the nitro-group replaced by carboxyl, an acid is obtained which is identical with that from santonin. The nitro-group is shown to occupy the para-position to the phthalide group, as it yields a nitrile which is readily saponified, whilst an *o*-nitrile would be difficult to saponify, as in the case of cyanocuminic acid. The nitration of methylphthalide (Giebe, Abstr., 1897, i, 63) and of diethylphthalide (Bauer, Abstr., 1904, i, 417; 1908, i, 274) is also known to yield para-derivatives. An attempt to prove the constitution directly by conversion into the hydroxy-compound, reduction, and distillation with lime, in order to examine the *isopropylphenol* produced, failed owing to the smallness of the yield obtained on reducing the hydroxyl compound with phosphorus and hydriodic acid.

The reduction of nitrodimethylphthalide with aluminium amalgam yields, instead of the amino-compound, an orange-yellow, crystalline

substance, m. p. 225—230°, devoid of basic properties. 5-Aminodimethylphthalide, $\text{NH}_2\cdot\text{C}_6\text{H}_3\langle\begin{smallmatrix}\text{CMe}_2\\\text{CO}\end{smallmatrix}\rangle\text{O}$, obtained by reduction with stannous chloride, forms white leaflets, m. p. 117°. The *picrate* has m. p. 198—200°, softening at 192°. The *acetyl* derivative has m. p. 172—175°.

5-Hydroxydimethylphthalide, obtained by the diazo-reaction, forms white needles, m. p. 151—153°; its *acetyl* derivative has m. p. 76—78°; the *methyl ether* softens at 92—93° and melts at 98—99°.

In the attempt to prepare cyanodimethylphthalide by the diazo-reaction, an additive compound, m. p. 211—212°, is obtained, from which the compound may be isolated by heating in carbon dioxide, when cuminaldehyde volatilises, and a residue of 5-cyanodimethylphthalide, softening at 154° and melting at 159—160°, is obtained. Hydrolysis converts it into dimethylphthalidecarboxylic acid, identical with that obtained by other methods. C. H. D.

Retene. PAUL LUX (*Monatsh.*, 1910, 31, 939—949. Compare Bucher, this vol., i, 239).—Methylisopropylidiphenamide,

(this vol., i, 239), crystallises from benzene, and has m. p. 204—206° (corr.). When treated with bromine and potassium hydroxide solution, it yields 2:2'-diamino-3'-methyl-4-isopropylidiphenyl,

which forms colourless crystals, m. p. 89—90° (corr.). The *hydrochloride*, $\text{C}_{16}\text{H}_{20}\text{N}_2\cdot 2\text{HCl}$, melts above 240°. A better yield of the diamine can be obtained by using Jeffrey's method (*Abstr.*, 1897, i, 315). The *urethane*, $\text{CO}_2\text{Me}\cdot\text{NH}\cdot\text{C}_6\text{H}_3\text{Me}\cdot\text{C}_6\text{H}_3\text{Pr}\cdot\text{NH}\cdot\text{CO}_2\text{Me}$, forms colourless crystals, m. p. 239—241° (decomp.), and when heated with slaked lime yields the diamine. It has not been found possible to diazotise the diamine and obtain the corresponding hydrocarbon; the product formed appears to be *methyl isopropylcarbazole*, $\text{C}_{16}\text{H}_{17}\text{N}$. It crystallises in glistening prisms, m. p. 124° (corr.), and yields a *picrate*, m. p. 166—167° (corr.).

3'-Methyl-4-isopropylidiphenamic acid,

has m. p. 198—199°.

J. J. S.

Preparation of *o*-4-Nitroso-1-hydroxynaphthoylbenzoic Acid. ANILFARBEN- & EXTRAKT-FABRIKEN VORM. JOH. RUD. GEIGY (D.R.-P. 223306).—*o*-4-Nitroso-1-hydroxy- β -naphthoylbenzoic acid (annexed formula) is prepared by treating finely-

powdered *o*-1-hydroxy- β -naphthoylbenzoic acid with a concentrated solution of sodium nitrite, and keeping the paste well stirred at a temperature of 45° during six or eight hours, with further additions of water as necessary to keep it at a workable consistency. It forms sulphur-yellow crystals, m. p. 195° (the *sodium salt* is sparingly soluble), and on reduction yields *o*-4-amino-1-hydroxy- β -naphthoylbenzoic acid.

F. M. G. M.

Preparation of *o*-4-Chloro-1-hydroxy- β -naphthoylbenzoic Acid. ANILINFARBEN- & EXTRAKT-FABRIKEN VORM. JOH. RUD. GEIGY (D.R.-P. 224538).—The action of ordinary

chlorinating agents on *o*-1-hydroxy- β -naphthoylbenzoic acid is violent and leads to the formation of mixed products; it is now found that sulphuryl chloride in ethereal solution and at a low temperature gives a good yield of 4'-chloro-1'-hydroxy- β -naphthoyl-*o*-benzoic acid.

bright yellow prisms, m. p. 211°.

F. M. G. M.

Action of Light on Benzaldehyde in the Presence of Iodine. LUIGI MASCARELLI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 300—302. Compare this vol., i, 389, 561).—Among the products of this reaction, isobenzil, $\text{COPh}\cdot\text{O}\cdot\text{CPh}\cdot\text{CPh}\cdot\text{O}\cdot\text{COPh}$, has now been identified.

R. V. S.

Action of Light on *p*-Tolualdehyde in the Presence of Iodine. LUIGI MASCARELLI and G. RUSSI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 239—242. Compare this vol., i, 389, 561).—The results obtained were similar to those already recorded in the case of benzaldehyde. The aldehyde when exposed to light in the presence of iodine for three years yielded (1) *p*-toluic acid; (2) a trimeric *tolualdehyde*, forming thin, colourless, prismatic crystals, m. p. 215°; (3) *p*-tolyl *p*-toluate, a pale yellow oil, b. p. 213—217°/15 mm., identical with that prepared by the Schotten-Baumann reaction (b. p. 224—228°/20—21 mm.).

R. V. S.

Nature of the Catalytic Action of Zinc Chloride by the Condensation of Aromatic Ketones with Amines. G. REDDELIEN (*Ber.*, 1910, 43, 2476—2480. Compare this vol., i, 118).—Benzophenone condenses readily with aniline and its derivatives in presence of anhydrous zinc chloride, or of the corresponding zinc chloride amine salt, for example, aniline zinc chloride, $\text{ZnCl}_2(\text{NH}_2\text{Ph})_2$. When the amine forms no additive compound with zinc chloride (for example, *m*-nitroaniline, *m*-aminophenol), no condensation takes place. The zinc chloride amine compounds are not hygroscopic, and they act only as amine carriers, whereas the elimination of water from compounds, $\text{OH}\cdot\text{CR}_2\cdot\text{NHR}$, is brought about by the high temperature of the reaction. There is no interaction when benzophenone and aniline zinc chloride alone are heated at 160°, reaction immediately beginning when aniline is introduced. Benzophenoneanil is partly decomposed by zinc chloride at 160° with the formation of the compound $\text{ZnCl}_2(\text{NH}_2\text{Ph})_2$.

The additive compounds of zinc chloride with the toluidines, xylydine, and phenylenediamine also act as catalysts. Anhydrous zinc chloride also acts as a condensing agent when more is used at a higher temperature, and the reaction is continued for a longer period. It acts not as a catalyst, but in withdrawing water.

On heating acetophenone with aniline in presence of zinc chloride, the chief product is triphenylbenzene, m. p. 170°. When zinc chloride

aniline is used, acetophenoneanil is obtained as a pale yellow oil, b. p. $198-200^{\circ}/37$ mm., solidifying to colourless crystals, m. p. 41° . It dissolves in concentrated sulphuric acid with an intense yellow coloration.

The following keto-imines have been condensed by means of zinc chloride amine or zinc chloride:

Bis-diphenylmethylene-p-phenylenediamine, $\text{CPh}_2\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{N}\cdot\text{CPh}_2$, crystallises in golden-yellow, jagged plates, m. p. 180° . *p-Phenylenediamine zinc chloride*, $\text{ZnCl}_2\cdot\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$, forms bunches of colourless, microscopic needles.

Fluorenoneanil, $\text{C}(\text{C}_6\text{H}_5)_2\cdot\text{NPh}$, separates in golden-yellow needles grouped in rosettes, m. p. 89° . *Fluorenone-p-toluidine* forms lustrous, golden-yellow needles, m. p. 124° .

Diphenylenemethylene-p-aminophenol forms large, lustrous, dark brown plates, which become yellow on heating, m. p. $218-219^{\circ}$.

Bis-diphenylenemethylene-p-phenylenediamine crystallises in lustrous, red needles, m. p. 278° .
E. F. A.

Keto-anils. MAX BUSCH and FERD. FALCO (*Ber.*, 1910, 43, 2557-2564).—The easy production of keto-anils, $\text{NR}\cdot\text{CR}'\text{R}''$, by the interaction of benzanilideimino-chloride and magnesium alkyl halogenides in ether (this vol., i, 729) led the authors to hope they had discovered a satisfactory method of testing the Hantzsch-Werner hypothesis of the stereoisomerism of trivalent nitrogen compounds (compare Straus and Ackermann, this vol., i, 241). *Deoxybenzoinanil*, $\text{NPh}\cdot\text{CPh}\cdot\text{CH}_2\text{Ph}$, m. p. 89° , is ultimately obtained by the interaction of benzanilideimino-chloride and an excess of magnesium benzyl chloride; it forms slender needles and decomposes easily in alcoholic solution, especially by treatment with dilute sulphuric acid, into deoxybenzoin and aniline. When heated above 100° for two to three hours it is oxidised to a great extent to benzanil; by exposing its solution in petroleum to sunlight for five to six hours, benzanilide and benzanil are formed. (Equal molecular quantities of benzanilideimino-chloride and magnesium benzyl chloride react in ether ultimately to form chiefly diphenylbenzenylamidine.)

Phenyl α -naphthyl ketoneanil, $\text{NPh}\cdot\text{CPh}\cdot\text{C}_{10}\text{H}_7$, obtained from the product of the reaction between magnesium α -naphthyl bromide and benzanilideimino-chloride in ether, exists in two forms: long, monoclinic leaflets, m. p. 101° , and triclinic prisms, m. p. 95° . The former are obtained from concentrated, the latter from dilute, solutions, and either can be obtained from a solution of the other by inoculation. Despite the difference of m. p. and of crystalline form, the two substances are regarded as dimorphous forms of an individual substance and not as stereoisomerides, because they are identical as regards colour, solubility, and chemical behaviour (*hydrochloride*, m. p. $187-188^{\circ}$; *picrate*, m. p. 165°).
C. S.

m-p-Ditolyl Ketone. JAMES LAVAUX and MAURICE LOMBARD (*Bull. Soc. chim.*, 1910, [iv], 7, 913-915).—The action of methylene chloride on toluene in presence of aluminium chloride leads to the production of a mixture of hydrocarbons, which on oxidation furnishes

m-p-ditolyl ketone as one product. The ketone and some of its derivatives are described.

The yield of hydrocarbons in the condensation is about 60% of the theoretical, and the product consists of ditolylmethane and dimethylanthracene in the proportion 20:1. The ditolylmethane boils at 288–290°, and on oxidation with chromic acid in acetic acid furnishes *benzophenone-3:4'-dicarboxylic acid*, m. p. 337° (corr.), which crystallises from alcohol in small needles, and *m-p*-ditolyl ketone, m. p. 70.5°, which forms acicular crystals from boiling alcohol, and is readily soluble in organic solvents, particularly in chloroform; the *oxime*, m. p. 128–129°, forms needles, and the *semicarbazone*, m. p. 183° (approx.), crystallises from alcohol.

The constitution of the ketone is established by the fact that it yields on fusion with potassium hydroxide, *m*- and *p*-toluic acids, and the amides of these two acids on treatment with sodamide. T. A. H.

Reaction between *p*-Benzoquinone and Hydrogen Chloride. ARTHUR MICHAEL and PHILIP H. CORR (*J. pr. Chem.*, 1910, [ii], 82, 297–306).—The author takes exception to Thiele's and to Posner's explanation of the action of hydrogen chloride or bromide on *p*-benzoquinone by the theory of partial valency; this theory requires that halogenated quinols should be the first products of the reaction, whereas the author shows that in chloroform or carbon tetrachloride the initial product is quinhydrone or a mixture of quinhydrone and chloroquinone. C. S.

Mechanism of Quinone Reactions. Reply to Posner. ARTHUR MICHAEL (*J. pr. Chem.*, 1910, [ii], 82, 306–321).—The author gives a further reply to Posner's criticisms (Abstr., 1904, i, 1029; 1909, i, 809) of his explanations of the reactions between *p*-benzoquinone and hydrogen chloride, aniline, and thiophenol (Abstr., 1904, ii, 164; 1909, i, 494). C. S.

Quinonoid Compounds. XXIII. Oxidation of Aniline. RICHARD WILLSTÄTTER and RIKŌ MAJIMA (*Ber.*, 1910, 43, 2588–2593).—A new example of ortho-condensation during the oxidation of aniline is furnished by the use of ferric chloride. A solution of aniline in 6% sulphuric acid is treated at 30° with a concentrated solution of ferric chloride (equiv. to 2½O), whereby a mixture of aniline-black and dianilinobenzoquinone is produced, from which the latter may be isolated by sublimation in a vacuum, by extraction with boiling chloroform, or by extraction with nitrobenzene and sublimation at 15 mm. in carbon dioxide of the brown, crystalline product obtained from the cold solution. By reduction with tin and warm hydrochloric acid, dianilinobenzoquinone is converted into anilinoquinol, a solution of which in *N*-hydrochloric acid is oxidised by careful treatment with *N*/10-ferric chloride to *anilino-p-benzoquinone*,

m. p. 117–118°. This substance, which is much more intensely coloured than more complex anilinobenzoquinones, forms glistening,

bronze plates, which are brownish-yellow by transmitted light, gives intensely red solutions, is stable to sulphurous acid, and is reduced by zinc and acetic acid to dihydroxydiphenylamine.

An aqueous 2% solution of aniline is oxidised by Caro's method with saturated potassium persulphate in the presence of calcium carbonate; the red, crystalline product, m. p. 252°, which is regarded as *dianilino-*

p-benzoquinonimine, $\text{NH} \cdot \text{C} \begin{array}{c} \text{C}(\text{NHPh}) \cdot \text{CH} \\ \text{CH} \cdot \text{C}(\text{NHPh}) \end{array} \text{C} \cdot \text{O}$, yields dianilino-benzoquinoneanil with aniline and acetic acid, is very stable to lead dioxide and sulphuric acid, and dissolves in concentrated sulphuric acid with a brownish-violet colour, which turns violet by the addition of alcohol and warming.

C. S.

Action of *p*-Benzoquinone on Diamines and Esters of Amino-acids. WILHELM SIEGMUND (*J. pr. Chem.*, 1910, [ii], 82, 409—414. Compare Schlenk, *Abstr.*, 1909, i, 807; Fischer and Schrader, this vol., i, 270).—By cooling a hot solution of *p*-benzoquinone (2 mols.) and diaminodiphenylmethane (1 mol.) in a little benzene, glistening, black, rhombic plates of a substance, $\text{C}_6\text{H}_4\text{O}_2 \cdot \text{CH}_2(\text{C}_6\text{H}_4 \cdot \text{NH}_2)_2$, m. p. 72—73°, are obtained, which gives a violet coloration with concentrated sulphuric acid. In a similar way, *p*-benzoquinone and diaminostilbene yield brownish-black, metallic crystals of a substance,

m. p. 130°, which gives a yellow coloration with sulphuric acid. A benzene solution of *p*-benzoquinone and methyl *p*-aminobenzoate in the proportion 3 : 2 yields, after the addition of petroleum, dark red leaflets of the substance, $\text{C}_6\text{H}_4\text{O}_2 \cdot 2\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{Me}$, m. p. 83°, which by prolonged boiling with *p*-benzoquinone in alcohol is converted into methyl *p*-benzoquinone-2 : 5-diaminobenzoate,

which crystallises in brown needles, and decomposes when heated.

C. S.

Stable Primary Nitrosoamine. GUSTAV HELLER and APOSTOLOS SOURLIS (*Ber.*, 1910, 43, 2581—2588).—4 : 6-Dinitroresorcinol (which forms a *diacetate*, m. p. 139°, and a *dibenzoate*, m. p. 343—344°) is suspended in glacial acetic acid and reduced by stannous chloride and 23% hydrochloric acid below 60°; by the addition of sodium acetate and acetic anhydride, the product of reduction is isolated as 6-nitro-4-acetylaminoresorcinol, m. p. 261° (decomp.), which is hydrolysed by concentrated hydrochloric acid, yielding the *hydrochloride*, m. p. above 300°, of 6-nitro-4-aminoresorcinol, m. p. 160—161° (decomp.). The reduction of 4 : 6-dinitroresorcinol by tin and hydrochloric acid and the treatment of the product with acetic anhydride yield 4 : 6-diacetylaminoresorcinol, m. p. 335° (decomp.), which forms a *dibenzoate*, m. p. 214°.

6-Nitro-4-nitrosoamino-3-hydroxy-o-benzoquinoneoxime,

obtained from aqueous 6-nitro-4-aminoresorcinol hydrochloride or

hydrobromide and sodium nitrite (2 mols.) at 0°, forms dark yellow, hexagonal plates, and explodes when heated. The substance is regarded as a nitrosoamine, and not as an *anti*-diazohydroxide, because it does not react with acetyl chloride or acetic anhydride, and its solution in alcoholic hydrogen chloride does not combine directly with alkaline β -naphthol; its solution in concentrated hydrochloric acid is very stable, and the diazonium salt thereby produced combines at once with alkaline β -naphthol, forming 6-nitro-3-hydroxy-1:2-quinoneoxime-4-azo- β -naphthol. The substance shows the character of a quinoneoxime, a 1% solution in dilute acetone dyeing chromed wool a tobacco-brown colour; in faintly alkaline β -naphthol solution, the dyed wool acquires a distinct blue tinge. When the nitrosoamine in concentrated hydrochloric acid is treated with copper powder in the cold, the hydrochloride, $C_6H_5O_2N_2Cl, HCl$, m. p. 204—205°, of 4-chloro-5-nitro-3-hydroxy-1:2-quinoneoxime, yellow needles, m. p. 155°, is obtained, a 1% solution of which produces a clearer and yellower tone on chromed wool than the nitrosoamine. C. S.

Preparation of Acetylchloroaminoanthraquinones. FARBWERKE FORM. MEISTER, LUCIUS & BRÜNING (D.R.-P. 224073).—Acetylchloroaminoanthraquinones, analogous to the phenyl compounds described by Bender (Abstr., 1887, 44), are readily obtained by the action of hypochlorous acid on an aqueous or dilute acetic acid solution or suspension of the required acetylaminanthraquinone; if glacial acetic acid is employed, nuclear substituted derivatives are formed.

Acetylchloro- β -aminoanthraquinone is prepared by heating the components together on the water-bath until a permanent yellow colour is obtained; it forms small needles, somewhat soluble in nitrobenzene.

Acetylchloro- α -aminoanthraquinone requires greater excess of hypochlorous acid and more prolonged heating for its preparation.

These compounds are initial substances in the preparation of dyes.

F. M. G. M.

Preparation of β -Anthraquinonylcarbimide from β -Aminoanthraquinone. FARBWERKE FORM. MEISTER, LUCIUS & BAFFING (D.R.-P. 224490).— *β -Anthraquinonylcarbimide*, m. p. 173°, is prepared by treating β -aminoanthraquinone with carbonyl chloride in nitrobenzene or xylene solution and keeping the mixture at the ordinary temperature until no red coloration is produced with dilute alcohol. The liquid is then heated to a temperature of 130—150°, when, on cooling, the product separates in colourless crystals. By treatment with moderately concentrated sulphuric acid, it is decomposed, yielding β -aminoanthraquinone with evolution of carbon dioxide.

F. M. G. M.

[Preparation of Aminoanthraquinone Thio-ethers.] FARBENFABRIKEN FORM. FRIEDRICH BAYER & Co. (D.R.-P. 224589).—An account of the preparation of dyes obtained by the action of aliphatic mercaptans on negatively substituted anthraquinone derivatives (containing either halogen, nitro- or sulphonic groups) in aqueous

alkaline solution. The following compounds are mentioned: 1-Amino-4-ethylthiolanthraquinone, bronze prisms; 1-benzoylamino-4-ethylthiolanthraquinone, bronze needles; 1-acetyl-amino-4-ethylthiolanthraquinone, red crystals; 1-amino-2:4-diethylthiolanthraquinone, red leaflets; 1:5-diamino-4:8-diethylthiolanthraquinone, steel-blue leaflets; sodium 1-ethylthiolanthraquinone-5-sulphonate, orange leaflets; 1:5-diethylthiolanthraquinone, yellow leaflets; sodium 1:4-diethylthiolanthraquinone-8-sulphonate, red needles.

The colour of the solutions of these substances in various solvents is tabulated in the patent.

F. M. G. M.

[Preparation of Benzoylaminoanthraquinones.] FARNEN-FABRIKEN VORM. FRIEDRICH BAYER & Co. (D.R.-P. 225232).—A tabulated list of substituted benzoylamino- and dibenzoyldiamino-anthraquinones and their condensation products, with the colours of their solutions in pyridine, concentrated sulphuric acid, when dyed on wool, and in the vat.

F. M. G. M.

Preparation of Arylsulphonaminoanthraquinones. FRITZ ULLMANN (D.R.-P. 224982).—When substituted halogen anthraquinones are heated with arylsulphonamides and potassium carbonate in the presence of copper acetate in boiling nitrobenzene solution (or, if necessary, at higher temperatures), the following reaction takes place:

1-*p*-Toluenesulphonaminoanthraquinone, long, yellow needles, m. p. 225°, was obtained from 1-chloroanthraquinone and *p*-toluenesulphonamide.

2-Iodoanthraquinone, needles, m. p. 170°, is prepared by the method described for 1-iodo-2-methylantraquinone (Scholl, Abstr., 1907, i, 540), and when treated as above yielded 2-*p*-toluenesulphonaminoanthraquinone; this forms yellow needles.

1:2-Anthraquinonylsulphonaminoanthraquinone, prepared from 1-chloroanthraquinone and anthraquinone-2-sulphonamide, is insoluble in the ordinary organic solvents, but dissolves in concentrated sulphuric acid, yielding a red solution.

1:5-Dibenzenesulphonyldiaminoanthraquinone, a yellow, crystalline powder, was obtained from 1:5-dichloroanthraquinone and benzenesulphonamide.

F. M. G. M.

Preparation of Reduction Products of Acenaphthenequinones. KALLE & Co. (D.R.-P. 224979).—Reduction products from acenaphthenequinones have previously been studied; it is found that less energetic reduction, or the employment of milder reducing agents, gives rise to different products.

The compound (probably I) is produced by the action of alkaline

reducing agents; it forms yellow prisms, m. p. 248°, may be crystallised from tetrachloroethane, and yields a *hydrogen sulphite* and an *acetyl*

derivative on treatment respectively with sodium hydrogen sulphite or acetic acid. The second compound (probably II) is obtained with acid, neutral, or alkaline reducing agents; it crystallises from alcohol in needles, has m. p. 254°, and forms two series of salts which are soluble in water. One alkali salt is pale blue, the other (when excess of alkali is employed) a deep violet blue; the *magnesium* salts are colourless. This substance can be acetylated, and combines with sodium hydrogen sulphite and with hydroxythionaphthens to form vat dyes.

F. M. G. M.

Preparation of Anthraquinone Derivatives. KINZLEBERGER & Co. (D.R.P. 223210).—When anthraquinone is heated at 160° with sodium hydroxide and zinc dust (or other alkaline reducing agents) it yields a *dianthranol*, $\text{C}_{18}\text{H}_{18}\text{O}_2$, m. p. 230°. This on oxidation with alkaline potassium permanganate gives a compound, $\text{C}_{18}\text{H}_{16}\text{O}_2 = \text{CO} < \text{C}_6\text{H}_4 > \text{C}:\text{C} < \text{C}_6\text{H}_4 > \text{CO}$, forming yellow crystals, which turn green on pressure and blacken at 300° without fusion.

F. M. G. M.

Behaviour of Some Derivatives of Phenylhydroxylamine. LUIGI ALESSANDRI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 122–129).—Additional reasons are adduced for the formula assigned (this vol., i, 552) to the product of the action of nitro-benzene on safrole, which is identical with that obtained by the action of phenylhydroxylamine on methylenedioxy-cinnamaldehyde. The double linking between carbon atoms appears to be connected with the fact that the substance is coloured, since the analogous derivatives of benzaldehyde and phenylacetaldehyde are white. Moreover, β -cyclocitral yields a colourless derivative, so that the double linking in the above compound is probably in the side-chain. Benzoylacetalddehyde also yields a yellow derivative, although the constitution of the latter is not quite clear.

The *N*-phenyloximes described yield with hydroxylamine the corresponding oxime and phenylhydroxylamine, and they are rapidly affected by light. The action of light has been investigated further in the case of some analogous compounds. The cinnamaldehyde derivative, when exposed to light in sealed tubes freed from air, yields cinnamaldehyde and cinnamylideneaniline, $\text{CHPh}:\text{CH}:\text{CH}:\text{NPh}$. At the same time small quantities of other substances are formed, and an odour of isonitrile is perceptible. The benzaldehyde derivative, when

exposed to sunlight and air, forms benzaldehyde, nitrosobenzene, and benzanilide (compare Ciamician and Silber, *Abstr.*, 1905, i, 335), in addition to small quantities of *o*-oxybenzene, *o*-hydroxyazobenzene, and dibenzaniline. Nitrosophenylhydroxylamine, $\text{O:NPh:N}\cdot\text{OH}$, should form diazobenzene hydroxide analogously, and, in fact, an alkaline solution of it containing α -naphthol deposits benzeneazonaphthol when exposed to light. The process is rapid enough to have application in photography. The salts of the isomeric phenylnitroamines,

are acted on similarly, but more slowly. The sodium derivative of nitrosophenylhydroxylamine yields nitrosobenzene rapidly in the light. Unsaturated nitro-derivatives, such as 7-nitrostilbene and piperonalnitroethane, are also decomposed by light.

When β -cyclocitral and phenylhydroxylamine are kept in a sealed tube in the dark for some days, *N*-phenyl- β -cyclocitraloxime, $\text{C}_{16}\text{H}_{21}\text{ON}$, is formed. It forms long, colourless needles, m. p. 109–110°. It is acted on by permanganate, nitrosobenzene being formed, and it is rapidly hydrolysed by dilute sulphuric acid. When it is exposed to light, it quickly resinifies, an odour of cyclocitral and isonitrile is observed, and nitrosobenzene is formed. The last-named substance can be recognised by means of test-papers impregnated with hydroxylamine hydrochloride, sodium carbonate, and α -naphthol. β -cyclocitraloxime, $\text{C}_{13}\text{H}_{17}\text{ON}$, prepared by the action of hydroxylamine on the above ether, or on β -cyclocitral, forms large, colourless rhomboidal crystals, m. p. 84°, has a characteristic odour, is volatile in steam, and is readily hydrolysed by acids. β -cyclocitralsemicarbazone, $\text{C}_{11}\text{H}_{19}\text{ON}_2$, forms a felted mass of colourless needles, m. p. 209° (decomp.); Tiemann (*Abstr.*, 1901, i, 158, 599) describes a semicarbazone, m. p. 166–167°. By the action of phenylhydroxylamine on benzoylacetalddehyde, a substance, $\text{C}_{16}\text{H}_{13}\text{O}_2\text{N}$, is obtained, crystallising in orange needles, m. p. 158° (decomp.), which when warmed with permanganate yields nitrosobenzene, but is stable towards light.

R. V. S.

Nerol and Thymol in French Lavender Oil. F. ELZE (*Chem. Zeit.*, 1910, 34, 1029).—From a French lavender oil, having D_{20}^{25} 0.889, n_D^{20} 1.4620, and saponification number 99, a portion boiling at 85–100°/5 mm. was separated by distillation under reduced pressure. From this thymol was obtained by extraction with a dilute solution of sodium hydroxide, and from the residue nerol was isolated as the acid phthalate.

T. A. H.

Molecular Rearrangements in the Camphor Series. III. Oxidation Products of *l*- and *d*-Lauroleone. WILLIAM A. NOYES and C. G. DERRICK (*J. Amer. Chem. Soc.*, 1910, 32, 1061–1064. Compare *Abstr.*, 1909, i, 133, 560).—Contrary to the authors' previous statements, the diketone obtained by oxidising *l*-lauroleone does not undergo condensation readily. It has b. p. 204°/750 mm. (corr.); the optical activity varies with the method of preparation. The *disemicarbazone* has m. p. 194° (corr.), but the *dioxime* and *phenylhydrazone* are oily.

The rotation of *d*-lauroleone varies with the method of preparation; a specimen prepared by the action of sodium nitrite on the hydro-

obloride of aminolauroic acid had $[\alpha]_D^{25}$ 28.15°, whilst the density and b. p. were identical with that of the *l*-form. Oxidation with cold alkaline permanganate gave a diketone, $C_8H_{14}O_2$; the diisemicarbazone, after melting at 192° (corr.), solidified, and then had m. p. 225° (corr.).

The properties of the oxidation products of laurolene are in accord with Eykman's representation of the structure of this substance (Abstr., 1907, i, 378). W. O. W.

Molecular Rearrangements in the Camphor Series. IV. Synthesis of Laurolene. WILLIAM A. NOYES and L. P. KYRIAKIDES (*J. Amer. Chem. Soc.*, 1910, 32, 1064—1068. Compare preceding abstract).—The dimethylcyclopentanone obtained by heating *d-ad*-dimethyladipic acid with lime is optically inactive. Grignard's reaction was applied to convert the product into 1:2:3-trimethylcyclopentanol, $C_8H_{16}O$, a liquid having b. p. 56—60°/8 mm., D_4^{20} 0.9121, n_D^{20} 1.4554. This substance loses water when heated, and is converted into laurolene; the transformation, however, is more easily effected by Zelinsky's method (Abstr., 1902, i, 2). The hydrocarbon thus prepared has h. p. 120—122°, n_D^{20} 1.4461, and on oxidation furnishes a diketone identical with that obtained from aminolauroic acid. The refractive index of synthetic laurolene is slightly less than that of the natural product, possibly through the presence of some ψ -laurolene.

The structure of laurolene as Δ^1 -1:2:3-trimethylcyclopentene is, therefore, fully established. W. O. W.

Molecular Rearrangements in the Camphor Series. V. Mechanism of the Reactions by which Laurolene is Formed. WILLIAM A. NOYES (*J. Amer. Chem. Soc.*, 1910, 32, 1068—1070. Compare preceding abstracts).—A theoretical discussion. A methyl group is assumed to become detached and to unite with an adjacent carbon atom in the formation of laurolene from camphanic acid (Crossley and Renouf, *Trans.*, 1906, 89, 27) and from aminolauroic acid or anhydride. W. O. W.

Some Thujene Derivatives. IWAN L. KONDAKOFF and W. SKWORZOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 497—504. Compare Abstr., 1904, i, 438).—The authors consider that the structure of the compounds in the thujene series has not yet been satisfactorily settled. Thujene has never yet been obtained in a pure state, the product consisting of a mixture of dicyclic thujenes together with terpene and some other hydrocarbon. When the thujene obtained by the xanthate method is treated several times with 1% potassium permanganate, a tricyclic hydrocarbon or some stereoisomeric thujene was obtained, having b. p. 147.5—149.5°, D_4^{20} 0.8220, n_D^{20} 1.44809, $[\alpha]_D^{20}$ +109.09°.

By removing hydrogen bromide from thujyl bromide, an unsaturated alcohol was obtained, b. p. 218—221°/760 mm., 96—100°/10 mm., D_4^{20} 0.9174, n_D^{20} 1.47936, $[\alpha]_D^{20}$ +13.22°. Similarly, from the chloride, the alcohol obtained has b. p. 205—208°, D_4^{20} 0.8947, n_D^{20} 1.46123, $[\alpha]_D^{20}$ +23.22°. The taste and odour of both alcohols are alike, and similar to that of menthol and terpineol. They do not yield urethanes, are largely converted into resins by the action of hydrochloric acid and

of succinic anhydride at 150° , are readily oxidised by concentrated potassium permanganate, and readily lose water. They are probably tertiary alcohols containing a five-membered ring, and are very similar to the alcohol obtained by Semmler from sabinene (Abstr., 1907, i, 145), excepting that in the latter the double bond is in the side-chain, whereas in the former it occurs in the ring.

By the action of hydrochloric acid on isothujene, and also on the alcohol described above, a *dihydrochloride*, $C_{10}H_{18}Cl_2$, b. p. $121.5-125.5^{\circ}/16$ mm., D^{20}_D 1.0697, n_D 1.48458, $[\alpha]_D +1.86^{\circ}$, is obtained, together with resinised products. When treated with sodium acetate, a *hydrocarbon*, $C_{10}H_{18}$, b. p. $176-180^{\circ}$, D^{18}_D 0.8540, n_D 1.47586, $[\alpha]_D +3.11^{\circ}$, was obtained, the constitution of which may be (II) or (III) if formula (I) is taken as that of isothujene.

Z. K.

Essential Oils. ROURE-BERTRAND FILS (*Sci. Ind. Bull. Roure-Bertrand Fils*, 1910, [iii], 1, 34-62).—[JUSTIN DUPONT and LOUIS LABAUNE.]—It has been shown previously that when cinnamyl alcohol in toluene is treated with hydrogen chloride at 100° , a chloride, C_9H_9Cl ,

is formed (this vol., i, 185). This is now shown to be cinnamyl chloride. On treatment with silver nitrate in alcohol, it yields a mixture of products, from which, by the action of sodium and subsequent fractional distillation, α -phenylallyl ethyl ether and cinnamyl ethyl ether were isolated. In addition, the mixture contains α -phenylallyl alcohol and cinnamyl alcohol (compare Charon, *Bull. Soc. chim.*, 1910, [iv], 7, 86). A good yield of the supposed linalyl chloride described already may be obtained by treating either linalool or geraniol in dry benzene with phosphorus trichloride (this vol., i, 184).

Hydrogen bromide reacts with geraniol or with *l*- or *d*-linalool, dissolved in toluene and maintained at 100° , to form a *bromide*, D^{15}_D 1.4450, $n_D \pm 0$, n_D^{15} 1.507, b. p. $102-103^{\circ}/6$ mm., and this, when treated with potassium acetate in presence of toluene, yields linalyl acetate. When the bromide is treated with sodium ethoxide, it yields geranyl ethyl ether, b. p. 218° ; with silver hydroxide, it gives linalool, and with silver nitrate, it furnishes linalol, geranyl ethyl ether, and possibly linalyl ethyl ether. In view of this complex reaction with silver nitrate, it is difficult to assign a constitutional formula to the bromide or the corresponding chloride.

Orange flowers collected in May and in October, 1909, yielded, by extraction with light petroleum, 736.3 and 663.6 grams respectively of total essential oil per 1000 kilos. of flowers. The May oil had D^{15}_D 0.8899, n_D^{15} 1.478, $n_D = -0.48$, acid value 0.7, saponification value 2.2, esters 24.6%, alcohols 51.0%, methyl anthranilate 3.53%. The

autumn oil had D^{15}_D 0.8887, n^{20}_D 1.476, $\alpha_D = -4.6'$, acid value 1.0, saponification value 95.8, esters 33.4%, alcohols 57.0%, methyl anthranilate 2.74%. These extracted oils differ from oil of neroli (distilled oil) in being levorotatory, indicating that a change in rotation occurs as the result of distillation in steam. The higher yield of oil in May and the greater richness of this oil in methyl anthranilate is probably due to more active metabolism in the plant at that period and to the warmer temperature. Extracted orange flower oil usually contains over 7.0% of methyl anthranilate, and the low yield in these two samples may have been a result of the severe winter preceding the orange flower harvest of 1909. Analyses of the two oils, after removal of methyl anthranilate by Hesse and Zeitschel's process (Abstr., 1901, ii, 209), gave constants indicating that the May oil was poorer in combined and total alcohols than the October oil, the quantity of free alcohols being about the same; similarly, the October oil was richer in the primary alcohols, geraniol and nerol. It seems likely, therefore, that in May the flowers draw their supply of oil from the young branches, and in October from the older branches. The results also afford a further proof of the formation of terpene compounds in green organs.

Myrica Gale yielded, by steam distillation, 0.0443% of a greenish-yellow, volatile oil, having D^{25}_D 0.8984, $\alpha^{20}_D = -5.16'$, acid value 3.48, saponification value 17.98, esters 5.1%, total alcohols 14.4%, and free alcohols 10.5%. The oil exhibited a powerful purgative action, as did also a resin contained in the plant.

Java patchouli leaves furnished 0.803% of oil having D^{15}_D 0.9564, $\alpha_D = -28.8'$, saponification value 6.3, saponification value of acetylated oil 40.4.

Oil of *Mentha arvensis* var. *Javanica* had D^{15}_D 0.9979, $\alpha_D = +0.94'$, acid value 69.8, saponification value 49.7, saponification value after acetylation 153.3, corresponding with esters 17.5%, total menthol 48.2%, free menthol 34.4%, ketones or aldehydes, traces or none. The oil did not deposit crystals at -15° .

Ylang-ylang oil from Mayotte had D^{15}_D 0.9324, $\alpha_D = -47.40'$, acid value 1.0, saponification value 113.4, corresponding with esters 39.7%, total alcohols 41.0%, and free alcohols 3.8%.

An oil from French Guiana had D^{15}_D 0.8864, $\alpha_D = 0.2'$, total alcohols 71.3%, esters 5.8%, and dissolved to the extent of 80% in sodium hydrogen sulphite solution. The oil had a lemon-like odour, and was described as derived from *Andropogon Nardus*, L. The results indicated that it was derived from *A. citratus*, De Cand., and was abnormally rich in citronellal and geraniol.

In continuation of previous work (this vol., i, 401), Delépine finds that samphire oil contains dipentene, not limonene; in addition to the constituents already described, the oil contains traces of two phenols (one crystalline, and the other possessing an odour of cresote), and a small quantity of an alcohol having an odour of roses, with other indefinite products.

T. A. H.

Essential Oils. SCHIMMEL & Co. (Bericht, October, 1910).—The fruits of *Pimenta acris* from Mauritius yielded 3.3% of bright brown

oil, D^{15} 0.9893, $\alpha_D -1^{\circ}20'$, n_D^{20} 1.51902, eugenol 70% (compare *Bull. Imp. Inst.*, 1910, 8, 4).

Camphor oil from German East Africa had D^{15} 0.9203, $\alpha_D +39^{\circ}42'$, n_D^{20} 1.47753, and deposited camphor on cooling.

Cocking (*Chemist and Druggist*, 1910, 77, 19) has devised a method for detecting "Illurin balsam" in copaiba balsam, depending on the fact that if oil be distilled from these balsams in ten equal fractions, those from copaiba balsam show increasing laevorotation, whilst those from Illurin balsam show increasing dextrorotation.

Bergamot oil adulterated with ethyl citrate yields on evaporation to constant weight on the water-bath, a residue having a saponification value above that found for a similar residue from genuine oil, namely, 160, and the increase in the value may be used to obtain a rough indication of the extent of the adulteration. In the saponified product citric acid may be detected by means of calcium chloride or by Denigès' test (*Abstr.*, 1899, ii, 454), the acid being first converted into acetonedicarboxylic acid by means of lead dioxide. Genuine bergamot oil contains only traces of citric acid, which, however, can be detected by Denigès' reaction. Genuine bergamot oil shows the same saponification value after heating at 100° during thirty or sixty minutes with $N/2$ -potassium hydroxide in alcohol, but if terpinyl acetate is present the saponification value increases with longer heating, and in any case is higher than that shown by genuine oil. Glycerol acetate may be detected by Jeancard and Satie's method, which depends on the partial extraction of the glycerol acetate with water. For the detection and estimation of sophistication by esters of non-volatile acids, 1.5 to 2 grams of oil is treated in the ordinary way for the determination of the total saponification value [acid and ester values]. The saponified product is made distinctly alkaline, evaporated to dryness, the residue acidified with sulphuric acid, and the acid value of the distillate determined. The difference between the "total saponification value" and the "volatile acid value" for genuine oil is not more than 7. These methods are applicable also to lavender and "petit grain" oils.

In Réunion geranium oil, linalool, α -terpineol, and phenylethyl alcohol were found in addition to traces of menthol and of an alcohol with an odour recalling that of borneol. Terpinenol may also be present.

Garlic contains according to Rindqvist (*Apoth. Zeit.*, 1910, 25, 105) a glucoside, *allin*, which is decomposed by a specific enzyme, *allisin*, yielding garlic oil and laevulose.

A Chinese peppermint oil had D^{15} 0.9187, $\alpha_D -44^{\circ}2'$, ester value 43.9, total menthol 64.0%, and was soluble in 2.5 or more volumes of 70% alcohol.

Japanese peppermint oil contains Δ^1 -menthenone, b. p. 235–237°/752 mm., D^{15} 0.9382, D^{20} 0.9343, $\alpha_D +1^{\circ}30'$, n_D^{20} 1.48411 (compare Wallach, *Abstr.*, 1908, i, 812). The semicarbazone exists in the sparingly soluble α -form already described by Wallach (*loc. cit.*), and also in a readily soluble β -form, m. p. 171–172°. With hydroxylamine it forms an *oxime*, m. p. 107–109°, and an *oxamino oxime*, m. p. 164–165°, which closely resembles the corresponding derivative of

carvenone, and must be constituted in an analogous manner, thus:

dibromide. With dehydrating agents, it yields *p*-cymene, and is oxidised by ferric chloride to thymol. Phosphorus pentachloride converts it into monochloroterpinene, and this on reduction with sodium in alcohol yields α -terpinene. On oxidation with permanganate the ketone furnishes formic acid, α -hydroxy- α -methyl- δ -isopropyladipic acid, m. p. 143°, α -isopropyl- γ -acetylbutyric acid (the *semicarbazone* has m. p. 158—159°), and α -isopropylglutaric acid, the third acid resulting from further oxidation of the second, and the fourth in like manner from the third. These reactions can best be explained by the formula assigned to the ketone by Wallach (*loc. cit.*). For the characterisation of the ketone in essential oils, it is best isolated as the compound with sodium hydrogen sulphite, and identified by means of the α -semicarbazone. According to Murayama, Japanese peppermint oil also contains *l*-limonene (*J. Pharm. Chim.*, 1910, [vii], 1, 549).

A sage oil from Cyprus had D_{20}^{25} 0.9263, n_D^{20} 1.46664, acid value 0, ester value 6.4, and acetyl ester value 36.0, and resembles Corfu sage oil.

From the first runnings of the distillation of sandalwood, the following constituents not previously observed have been isolated: (1) Santenone, $C_{15}H_{24}O$, m. p. 58—61°, b. p. 193—195°, n_D^{20} 1.4449 in alcohol, is identical with the ketone prepared by Aschan (Abstr., 1908, i, 94) and by Semmler, and named by the latter π -norcamphor (Abstr., 1907, i, 1062); it yields a liquid *oxime*, b. p. 110—113°/6 mm., from which the ketone is not regenerated by warming with acids. (2) "Santenone alcohol," $C_{15}H_{26}O$, m. p. 58—62°, b. p. 196—198°, is apparently identical with Semmler's π -norisoborneol (*loc. cit.*); on oxidation it yields santenone (π -norcamphor), furnishes a liquid *phenylurethane*, and is not etherified when warmed with alcohol and sulphuric acid. The isomeric alcohol (Aschan's santenol, *loc. cit.*; Semmler's π -norborneol, *loc. cit.*) on the contrary is etherified under these conditions, and yields, for example, *santenyl methyl ether*, $C_{16}H_{28}O$, b. p. 177—179°, D_{20}^{25} 0.9251, n_D^{20} 1.45841. It is suggested that Semmler's π -norborneol (Aschan's santenol) should now be called *isosantenol* and his π -norisoborneol should be named *santenol*. (3) A *hydrocarbon*, $C_{11}H_{18}$, b. p. 183°, D_{20}^{25} 0.9133, D_{20}^{20} 0.9092, n_D^{20} 1.47860, which may prove to be identical with Semmler's *nortricycloeksantalane* (Abstr., 1907, i, 432), since the latter, in view of Semmler's more recent work, must have the formula $C_{11}H_{18}$. (4) *Nortricycloeksantalal*, $C_{11}H_{16}O$, b. p. 86—87°/6 mm., 222—224°/761 mm., D_{20}^{20} 0.9938, n_D^{20} 1.48393, is identical with Semmler's product (this vol., i, 573). It yields a liquid *oxime*, b. p. 135—137°/7 mm., and on oxidation by air in dilute alkali furnishes the corresponding *acid*, m. p. 91—93°, n_D^{20} 1.3317 (in alcohol). On oxidation with permanganate, *teresantalic acid* is formed. The aldehyde can also be obtained from normal sandalwood oil. (5) *Teresantalol*, $C_{10}H_{16}O$, m. p. 112—114°, identical with Semmler and Bartlett's product (Abstr., 1907, i, 703) prepared from *teresantalic acid*. (6) *isoValeraldehyde*.

Müller's santalone (Abstr., 1900, i, 678) was isolated by means of the semicarbazone. It occurs associated with an isomeric ketone, yielding a semicarbazone, m. p. 208—209°, and an oxime, m. p. 100° (approx.). The sesquiterpene portion of the oil was separated by fractional distillation into α -santalene, b. p. 118°/7 mm., 252°/753 mm., D^{15}_D 0.9132, n_D^{20} -3°34', n_D^{20} 1.49205, and β -santalene, b. p. 125—126°/7 mm., D^{20}_D 0.8940, n_D^{20} -41°3', n_D^{20} 1.49460 (compare Semmler, Abstr., 1907, i, 781). It is probable that pure α -santalene is slightly dextrorotatory. On hydration, α -santalene furnishes a tertiary alcohol, $C_{15}H_{26}O$, b. p. 154—157°/5—6 mm., D^{15}_D 0.9787, D^{20}_D 0.9753, n_D^{20} 1.51725, which has a cedar-like odour, and on treatment with formic acid loses water. The portion of the hydrocarbon recovered from the hydration process is different from the original material (compare von Soden and Müller, Abstr., 1899, i, 924).

Brassica juncea seed from India yielded an oil having D^{15}_D 0.9950, n_D^{20} +0°13', n_D^{20} 1.51849, and soluble in 10 vols. of 70% alcohol. It boiled for the most part between 150—160° and 174—178°. The principal constituents were dimethyl sulphide, allyl cyanide, allylthiocarbimide (40%), and a crotonylthiocarbimide (50%), b. p. 175—176°, D^{15}_D 0.994, n_D^{20} +0°3', n_D^{20} 1.52398, which furnished a thiocarbimide, m. p. 69—70°.

Juniper berry oil contains camphene (compare Abstr., 1909, i, 818).

Chamaecyparis Lawsoniana furnished 1% of citron-yellow oil, D^{15}_D 0.9308, n_D^{20} +23°48', n_D^{20} 1.48844, acid value 3.7, ester value 61.6, acetyl ester value 78.8, containing some decaldehyde (?).

The leaves of *Cinnamomum glanduliferum* contained *d*-camphor. *Dacrydium Franklinii* wood yielded an oil, D^{15}_D 1.0443, n_D^{20} +0°6', n_D^{20} 1.53287, containing much methyleugenol with some eugenol.

Eugenia apiculata leaves furnished 1.27% of brown oil, D^{15}_D 0.892, n_D^{20} +12°40', n_D^{20} 1.47821, acid value 5.5, ester value 25.8, and acetyl ester value 65.3.

Perilla nankinensis leaf oil, D^{15}_D 0.9265, n_D^{20} -90°, n_D^{20} 1.49835, contains an aldehyde, b. p. 91°/4.5 mm., 104°/9 mm., 235—237°/750 mm., D^{20}_D 0.9645, D^{15}_D 0.9685, $[\alpha]_D^{20}$ -150.7°, n_D^{20} 1.50693, which yields an oxime, m. p. 102°, and a phenylhydrazone, m. p. 107.5°. The corresponding acid has m. p. 130°, and forms scaly crystals. A dextro-modification of the same aldehyde has been found in a "false camphor wood."

Thymbra spicata herb from Smyrna gave 1.5% of oil having an odour of thyme and containing 66% carvacrol. It had D^{15}_D 0.9460, n_D^{20} 0°, n_D^{20} 1.50675.

Xanthoxylum alatum fruits gave 3.7% citron-yellow oil, D^{15}_D 0.8653, n_D^{20} -23°35', n_D^{20} 1.48131, and 0.9% of a crystalline, odourless substance, m. p. 83°, from which a small yield of a benzoyl derivative, m. p. 89°, was obtained. The oil appeared to consist mainly of hydrocarbons, and its odour recalled that of phellandrene.

Alpinia galanga oil is lemon-yellow, possesses a pungent, aromatic odour, and shows the following constants: D^{15}_D 0.9847, n_D^{20} +4°20', n_D^{20} 1.51638, and contains, according to Ullée, pinene, cineol, camphor, and methyl cinnamate.

Gastrochilus pandurata oil resembles estragon and basil oils in odour,

and has D^{15}_D 0.8746, $\alpha_D + 10.24'$, n_D^{20} 1.48957, ester value 17.3, and is incompletely soluble in 10 vols. of 80% alcohol.

A résumé of recent work on the botany, pharmacology, analysis, and chemistry of essential oils is also given.

T. A. H.

Cerebron. IV. HERMANN LOENING and HANS THIERFELDER (*Zeitsch. physiol. Chem.*, 1910, 68, 464—470. Compare Abstr., 1907, i, 168).—Details are given of the preparation of cerebron from ox-brain, and the analysis of various fractions separated by extracting agents. The purest fraction was obtained in crystalline form, and contains C 69.19%, H 11.35%, and N 1.7%. The m. p. is 212—213°. Further work is promised on a second galactoside with which cerebron is usually mixed.

W. D. H.

Effect of Alkali on Melanin. ROSS AIKEN GORTNER (*J. Biol. Chem.*, 1910, 8, 341—363).—Alkali in small concentration readily destroys the greater portion of the melanin molecule, the nitrogen falling specially, whilst the carbon and oxygen percentages increase; the sulphur remains practically constant. If the concentration of alkali does not exceed 0.2%, a melanin is extracted from black wool, which is of constant composition, contains no ash, and is readily soluble in acids.

W. D. H.

Synergisin, the Prochromogen of the Respiration Pigment of Wheat Germs. WLADIMIR PALLADIN (*Biochem. Zeitsch.*, 1910, 27, 442—449).—The prochromogen of wheat, *synergisin*, is decomposed by emulsin with production of a chromogen which is oxidised by peroxylase without addition of hydrogen peroxide. The prochromogen is extracted by ethyl and methyl alcohol, and is precipitated by acetone. It is not soluble in ether.

Taka-diastase, like emulsin, decomposes synergisin with production of a chromogen which is oxidised by peroxylase. Pepsin is without action.

A number of substances were treated with emulsin and peroxylase in order to ascertain whether pigments are produced. Arbutin yielded a red coloration, less intense than that obtained with the chromogen from wheat, whilst the following compounds gave negative results: aesculetin, amygdalin, apiin, cholesterol, crategin, cyclamin, digitalin, filicin, galactose, inositol, lecithin, phytin, quercitrin, raffinose, salicin, saligenin, solanine, syringin, and tyrosine.

Synergisin is a phosphatide containing a carbohydrate group.

N. H. J. M.

Compounds of Acid Dyes with Various Organic Bases. LEOPOLD RADLBERGER (*Zeitsch. physiol. Chem.*, 1910, 68, 391—394. Compare Abstr., 1908, i, 1001).—By mixing hot aqueous solutions of the components and cooling, the following insoluble or sparingly soluble salts have been obtained. Biguanide sulphate (which crystallises in large plates or in slender needles) yields the salt,

with orange II, and $C_{24}H_{23}O_7N_{12}S_2$ with crystal-ponceau. Acetyl-

guanamine acetate yields an orange salt, $C_{20}H_{19}O_4N_7S_2H_2O$ (very hygroscopic when anhydrous), with orange II. C. S.

Causes of the Coloration of Animal Fibres. II. WILHELM SCIDA (*Zeitsch. physiol. Chem.*, 1910, 68, 381—390. Compare Abstr., 1907, ii, 112).—Having shown that aqueous guanidine hydrochloride yields with picric acid and with crystal-ponceau sparingly soluble, crystalline precipitates, the filtrate containing in the first case all, in the latter 94.2%, of the chlorine, the author uses a reagent prepared by dissolving 5 grams of guanidine hydrochloride and 3 grams of acetic acid in 100 c.c. of water to test the acidity or basicity of a series of dyes which do not give in aqueous solution precipitates with acids alone. The results are: (i) all purely basic, non-sulphonated dyes do not give precipitates; (ii) in dyes which are aminosulphonic acids a decrease of precipitability frequently accompanies an increase in the number of amino- and of sulphy-groups; the generalisation, however, is not always trustworthy; (iii) nearly all of the hydroxyazo-dyes examined (with the exception of eosamine-B and azomagenta G), and also picric acid and alizarin-red, are more or less quantitatively precipitated, the quantitative course of the reaction being influenced by the number and the position of the hydroxyl and the sulphy-groups; (iv) the precipitation of hydroxy-dyes containing free or alkylated amino-groups is less the greater the number of amino-groups present; (v) whilst tartrazine does not give a precipitate, dyes containing hydroxyl and carboxyl groups, or these and sulphy-groups, give precipitates whether amino-groups are present or not; however, dyes which contain amino- (or alkylated amino-) and carboxyl, but no hydroxyl, groups do not yield precipitates. The outstanding result of the experiments is the important rôle played in the fixing of acid dyes by basic substances, by phenolic hydroxyl and aromatic amino-groups, the carboxyl and sulphy-groups exerting a quite subordinate influence.

Having shown that preliminary treatment of animal fibres with phosphotungstic acid retards the fixation of acidic dyes (*Zeitsch. angew. Chem.*, 1909, 22, 2131), the author has examined the behaviour of the acid towards salts of guanidine. Any soluble salt of guanidine yields with phosphotungstic acid a white precipitate, which is easily soluble in ammonium hydroxide or carbonate; the precipitate remains colourless when boiled with a solution of an acidic dye, but instantly becomes coloured by the addition of a little ammonium hydroxide or carbonate, consequently experiments on guanidine in test-tubes follow quite the same course as those previously performed on animal fibres (*loc. cit.*). Since phosphotungstic acid is an excellent precipitant for the basic fission products of albumins, and since these products frequently contain the group NCN present in guanidine, there can be little doubt that the fixation of acidic dyes by albumins is due to these fission products or the NCN group contained therein; moreover, the chemical compounds formed by acidic dyes with animal fibres are probably constituted in stoichiometric proportions, since Radlberger has shown (Abstr., 1908, i, 1901) that the compounds of guanidine with acidic dyes are thus constituted.

An examination has been made of the behaviour of dyes towards

many substances related to the albumins or their fission products. The results are: (i) all aliphatic or cyclic substances containing the group $\text{N}\cdot\text{CO}\cdot\text{N}\cdot$ or $\text{N}\cdot\text{C}(\text{OH})\cdot\text{N}\cdot$, such as carbamide, biuret, cyanuric acid, barbituric acid, alloxan, uric acid, theobromine, caffeine, phenyl-carbamide, α -phenylhydantoin, glycine anhydride, phenylglycine anhydride, do not yield precipitates with acidic dyes; some of them possessing acidic character (barbituric acid, uric acid, cyanuric acid, ammeline, ammeline) form sparingly soluble compounds with basic dyes; (ii) all derivatives of guanidine with open chains which do not contain substituent acidic groups (aminoguanidine, dicyanodiamide, guanylcarbamide, higuamide, arginine) form sparingly soluble compounds with acidic dyes; (iii) all cyclic compounds containing the guanyl group give sparingly soluble or insoluble compounds with acidic dyes. It is noteworthy that most of the preceding substances which form insoluble or sparingly soluble compounds with acidic dyes are also precipitated by phosphotungstic acid. C. S.

Molecular Weight of Tannin. LEO F. ILJIN (*J. pr. Chem.*, 1910, [ii], 82, 422—424).—The molecular weight of tannin, purified by the author's processes (*Abstr.*, 1909, i, 503), has been determined by the ebullioscopic method in acetone in MacCoy's modification of Landsberger's apparatus; the values, varying between 1247 and 1637, confirm those of Sahanéeff and of Walden. The author is of opinion that crude tannin contains, in addition to digallic acid and Nierenstein's leucotannin, a not inconsiderable quantity of a complex derivative of gallic acid, for which the name "tannin" should be reserved. C. S.

δ -Hydroxymethylfurfuraldehyde as the Cause of Some Colour Reactions of Hexoses. WILLIAM ALBERDA VAN EKENSTEIN and JAN J. BLANKSMA (*Ber.*, 1910, 43, 2355—2361. Compare *Abstr.*, 1909, i, 288; this vol., i, 461).—The compound previously described as β -hydroxy- δ -methylfurfuraldehyde is now shown to be the ω -hydroxy-compound, $\text{O} \begin{array}{c} \text{C}(\text{CHO})=\text{CH} \\ \diagdown \\ \text{C}(\text{CH}_2\cdot\text{OH})\cdot\text{CH} \end{array}$ as it can be obtained readily from chitose (Fischer and Andreae, *Abstr.*, 1903, i, 678), and when oxidised yields hydroxymethylpyromucic acid, $\text{O} \begin{array}{c} \text{C}(\text{CO}_2\text{H})=\text{CH} \\ \diagdown \\ \text{C}(\text{CH}_2\cdot\text{OH})\cdot\text{CH} \end{array}$ (compare Kiermayer, *Abstr.*, 1896, i, 144), identical with the acid prepared by Fischer and Andreae (*loc. cit.*) and by Fenton and Gostling (*Trans.*, 1899, 75, 429). J. J. S.

ω -Hydroxymethylfurfuraldehyde and its Relationship to Cellulose. ERNST ERDMANN (*Ber.*, 1910, 43, 2391—2398).— ω -Hydroxymethylfurfuraldehyde (compare Alberda van Ekenstein and Blanksma, preceding abstract) can be prepared from Fenton and Blanksma, preceding abstract) can be prepared from Fenton and Gostling's crude ω -bromomethylfurfuraldehyde (*Trans.*, 1901, 79, 361, 807) by shaking with aqueous alcoholic silver acetate and extracting with ether. It has b. p. $72^\circ/0\cdot002$ mm., and the yield is 5.5 grams from 150 grams of filter paper. It has a pleasant odour, D_4^{20} 1.1022, and gives the usual aldehyde reactions. Its semioxazurone, $\text{C}_8\text{H}_9\text{O}_4\text{N}$,

forms colourless needles, m. p. 216°. When heated under pressure with oxalic acid solution at 134°, it yields an oil from which a *phenylhydrazone*, m. p. 137°, has been isolated. The same phenylhydrazone can be obtained from the oil, b. p. 110°/0.002 mm., formed as a by-product in the preparation of the ω -hydroxymethyl compound. It is suggested that this oil, h. p. 110°/0.002 mm., is identical with the product obtained by Kiermayer from sucrose (Abstr., 1896, i, 144). Its semioxazone is not molten at 260°.

J. J. S.

Action of Methyl Sulphate on Dimethylpyrone. ADOLF VON BAEYER (*Ber.*, 1910, 43, 2337—2343).—Kehrmann and Duttonhöfer's dimethylpyrone methiodide (Abstr., 1906, i, 447) is shown to have the formula $\text{I} \cdot \text{O} \begin{smallmatrix} \text{CMe} \cdot \text{CH} \\ \text{CMe} \cdot \text{CH} \end{smallmatrix} > \text{C} \cdot \text{OMe}$.

The parent substance, $\text{I} \cdot \text{O} \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{CH} \cdot \text{CH} \end{smallmatrix} > \text{CH}$, is termed pyroxonium iodide.

Dimethyl-p-methoxypyroxonium perchlorate, $\text{OMe} \cdot \text{C}_5\text{H}_2\text{Me}_2\text{O} \cdot \text{ClO}_4$, is obtained when dimethylpyrone and methyl sulphate are heated at 50° until the mixture becomes orange-coloured, and the cold product is treated with 20% perchloric acid solution. It is also formed by the action of perchloric acid solution on Kehrmann and Duttonhöfer's iodide. It crystallises from methyl alcohol, is sparingly soluble in cold water, and is resolved into its components when boiled with water for some time. An aqueous solution of ammonium carbonate converts the perchlorate or the iodide into 4-methoxylutidine, the picrate of which melts at 154°, and a solution of sodium acetate or water and magnesium carbonate react with the perchlorate, yielding the *methyl ether* of the enolic form of diacetylacetone, $\text{CH}_3\text{Ac} \cdot \text{C}(\text{OMe}) \cdot \text{CHAc}$, as a colourless oil.

J. J. S.

Preparation of Coumarin. FRITZ RASCHIG (D.R.-P. 223684).—The synthetical production of coumarin has been checked by the cost of the salicylaldehyde employed in the usual method of preparation; it is found that this can be replaced by an *o*-tolyl ester containing two atoms of chlorine in the side-chain.

Di-*o*-chlorotolyl phosphate (obtained by treating *o*-tolyl phosphate with chlorine at 160—180°) is mixed with anhydrous sodium acetate and heated at about 180° during six hours; the temperature is then raised to 220°, when pure coumarin distils and solidifies in the receiver. The phosphoric acid can be replaced by other acids.

F. M. G. M.

Constitution of α -Pyrocresol. FRANZ ZMERZLIKAR (*Monatsh.*, 1910, 31, 897—902. Compare Schwarz, Abstr., 1883, 204; Bott, *J.C.S.I.*, 1887, 6, 646; Bott and Miller, *Trans.*, 1889, 55, 51).—When α -pyrocresol oxide is fused with potassium hydroxide, the products are *m*-hydroxy-*p*-toluic acid ($\text{Me} : \text{OH} : \text{CO}_2\text{H} = 1 : 3 : 4$), *m*-hydroxyterephthalic acid, and *m*-cresol.

The formation of these compounds is readily accounted for on the assumption that α -pyrocresol oxide is 4:2'- or 4:4'-dimethylxanthone,

$\text{C}_6\text{H}_3\text{Me} \begin{smallmatrix} \text{O} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}_6\text{H}_3\text{Me}$; α -pyrocresol itself would then be the corresponding dimethylxanthan, $\text{C}_6\text{H}_3\text{Me} \begin{smallmatrix} \text{O} \\ \diagup \quad \diagdown \\ \text{CH}_2 \end{smallmatrix} \text{C}_6\text{H}_3\text{Me}$. The identity of synthetical 4:4'-dimethylxanthone (Weber, Abstr., 1892, 1093) with α -pyrocresol oxide has been proved, and hence α -pyrocresol is 4:4'-dimethylxanthan. J. J. S.

Preparation of Phenoxozone. FARBENFABRIKEN VORM. FRIEDRICH BAYER & Co. (D.R.-P. 223367).—The preparation of phenoxozone, m. p. 118–119°, has previously been described (Ullmann and Stein, Abstr., 1906, i, 258); it is now found that it can be prepared in 74% yield by gradually heating sodium *o*-chlorophenoxide to 220° in an iron retort, and subsequently distilling under a pressure of 20–30 mm. F. M. G. M.

Preparation of Thionaphthen Derivatives from Arylthiolacetic Acids and their Derivatives. BADISCHE ANILIN- & SODA-FABRIK (D.R.-P. 224567).—When arylthiolacetic acids of the type $\text{R}\cdot\text{S}\cdot\text{CH}_2\cdot\text{CO}_2\text{R}'$ (where R is a simple or substituted benzene ring, or naphthalene residue, and R' hydrogen, a metal, alkyl, or aryl group) are treated with such reagents as phosphoric oxide, zinc, or aluminium chlorides, chlorosulphonic acid, or anhydrous oxalic acid, the following inner condensation takes place:

This reaction has only been studied previously with phenyl-, *o*- and *p*-tolyl-, and *p*-bromophenyl-thiolacetic acids, but has now been extended to naphthalene derivatives; the products when pure are colourless compounds soluble in alkali, and yielding vat dyes on oxidation.

2-Hydroxy-4-methylthionaphthen is prepared by heating ethyl *p*-tolylthiolacetate (obtained from thio-*p*-cresol and ethyl chloroacetate) with phosphoric oxide at 100–150°, and separating the product by distillation in steam; it forms long, colourless needles, m. p. 103°.

4-Chloro-2-hydroxythionaphthen, colourless needles, m. p. 100°, is similarly prepared from *p*-chlorophenylthiolacetic acid (m. p. 107°).

The compound, obtained from sodium α -naphthylthiolacetate, when treated with chlorosulphonic acid at 0–5° is yellow, and not volatile in steam. F. M. G. M.

Substituted Rhodanines and their Condensation Products with Aldehydes. IX. OSKAR ANTULICH (*Monatsh.*, 1910, 31, 891–895).—Ammonium *p*-anisylidenedithiocarbamate, prepared by Losanitsch's method (Abstr., 1907, i, 693), reacts with ethyl chloroacetate, yielding *p*-anisylrhodanine, $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{N} \begin{smallmatrix} \text{CS}\cdot\text{S} \\ \diagup \quad \diagdown \\ \text{CO}\cdot\text{CH}_2 \end{smallmatrix}$, which crystallises from alcohol in yellow plates, m. p. 153°. The following condensation products have been obtained by the action of a glacial acetic acid solution of an aromatic aldehyde on the rhodanine.

1-*p*-Anisyl-3-benzylidenetherhodanine, $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{N} \begin{smallmatrix} \text{CS}\cdot\text{S} \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{C}\cdot\text{CHPh}$,

lemon-yellow prisms, m. p. 190°; 1-*p*-anisidyl-3-*m*-nitrobenzylidenes-rhodanine, $C_{17}H_{12}O_4N_2S_2$, a chrome-yellow, crystalline powder; 1-*p*-anisidyl-3-*p*-hydroxybenzylidenes-rhodanine, $C_{17}H_{13}O_4NS_2$, yellow needles from acetone, m. p. 258°; 1-*p*-anisidyl-3-*p*-dimethylaminobenzylidenes-rhodanine, $OMe \cdot C_6H_4 \cdot N \begin{smallmatrix} CS \cdot S \\ CO \end{smallmatrix} C : CH \cdot C_6H_4 \cdot NM_{e_2}$, orange-red plates, m. p. 219°, and 1-*p*-anisidyl-3-*p*-hydroxy-*m*-methoxybenzylidenes-rhodanine, $C_{15}H_{15}O_4NS_2$, pale orange-coloured, crystalline powder, m. p. 210°.

J. J. S.

Preparation of Formyl Derivatives of Morphine Alkaloids. FÄRGENFABRIKEN VORM. FRIEDRICH BAYER & Co. (D.R.-P. 222920).—The formyl derivatives of the morphine alkaloids are readily obtained by heating either the bases, their salts, or halogen compounds with formic acid or sodium formate, the alcoholic hydroxyl of the base being the point of attack.

Formylcodeine, colourless crystals, m. p. 180°, is prepared by boiling dry codeine with an excess of formic acid (100%) during five or six hours; it is insoluble in water, and sparingly so in alcohol and ether.

Formylmorphine is obtained by boiling together dry morphine hydrochloride (10 parts), sodium formate (5 parts), and formic acid (50 parts). It has m. p. 220° (about), and at 253° decomposes into its progenitors; the salts are crystalline. The formyl derivatives of morphine ether and of methylmorphinemethine can be similarly prepared.

F. M. G. M.

Preparation of Morphine Esters of Acylaromatic Hydroxy-carboxylic Acids. J. D. RIEDEL (D.R.-P. 224197).—When morphine is treated with the acid chlorides of acylphenolcarboxylic acids, compounds of the type $C_{17}H_{18}O_2N \cdot OCO \cdot R \cdot OR'$ (R = an arylene, R' = an acyl) and of great therapeutic value are produced.

p-Acetoxybenzoylmorphine, $C_{25}H_{25}O_6N$, long, prismatic needles sintering at 225°, m. p. 232° (with decomp.), was prepared as follows: *p*-Acetoxybenzoic acid, m. p. 196°, obtained from *p*-hydroxybenzoic acid and acetic anhydride, was treated with phosphorus pentachloride and the mixture distilled in a vacuum, yielding *p*-acetoxybenzoyl chloride, which after distillation at 161–162°/12 mm. solidified to long needles, m. p. 30°. This chloride (dissolved in chloroform) was slowly shaken with morphine in aqueous alkaline solution, the liquids separated, and the product obtained in crystalline form by the addition of ethylacetate. The methochloride, small prisms, was obtained by the action of methyl sulphate and sodium chloride on the base.

p-Methyl-carbonatobenzoylmorphine, $C_{26}H_{26}O_5N$, was analogously prepared from *p*-methyl-carbonatobenzoyl chloride (Fischer, Abstr., 1908, 94, i, 892); it forms colourless needles, m. p. 175–176° (with decomp.). The hydrochloride crystallises from either methyl or ethyl alcohol in large prisms containing one molecule of the respective alcohol of crystallisation, and with m. p. 165–190° (indefinite). When shaken with the requisite quantity of dilute alcoholic ammonia and kept at the ordinary temperature, the *p*-methyl-carbonato-group is eliminated, and *p*-hydroxybenzoylmorphine, $C_{24}H_{24}O_5N$, m. p. 230–237° (with

decomp.), separates out; the *hydrochloride* forms prismatic needles; the *methobromide*, small leaflets, was prepared by the action of methyl sulphate and potassium bromide in chloroform solution.

F. M. G. M.

Preparation of Halogenhydroxyalkyl-substituted Xanthine Bases. CHEMISCHE WERKE VORM. DR. HEINRICH BYK (D.R.P. 224159).—When xanthine bases are treated with substituted halogen alkyl oxides, reaction occurs with the iminic hydrogen.

Chlorohydroxypropyltheophylline,

m. p. 141–143°, is prepared by heating theophylline with epichlorohydrin in a closed vessel at 130° during several hours with continual stirring; it is readily soluble in water, and when boiled with an alkaline hydroxide is converted into dihydroxypropyltheophylline.

F. M. G. M.

Strychnine Alkaloids. IX. Derivatives of Strychninesulphonic Acid I. and Oxidation of Bromostychnine. HERMANN LEUCHS and PAUL BOLL (*Ber.*, 1910, 43, 2362–2374. Compare Abstr., 1909, i, 120, 671).—The sulphonic acid group of strychninesulphonic acid is not attached to one of the benzene nuclei, and hence the acid readily yields substitution products, for example, mono- and di-chloro-derivatives, a monobromo-, a nitro- and a nitrobromo-derivative. Strychnine itself yields a hydrate of a dinitro-derivative, and it is probable that one of the nitro-groups of this derivative occupies the same position as the sulphonic group in strychninesulphonic acid. The nitrosulphonic acid is readily reduced to the corresponding amino-acid, and with alkaline reducing agents, azostychninesulphonic acid is also formed. So far it has not been found possible to prepare diazo- and hydroxy-compounds corresponding with the amino-derivative. The sulphonic acid group of strychninesulphonic acid is not removed by heating with concentrated hydrochloric acid, but an atom of chlorine is introduced: $\text{C}_{21}\text{H}_{22}\text{O}_5\text{N}_2\text{S} + \text{HCl} = \text{C}_{21}\text{H}_{21}\text{O}_4\text{N}_2\text{S} + \text{H}_2\text{O}$, and this chloro-acid when boiled with water loses hydrogen chloride, yielding a product isomeric with the original sulphonic acid and termed isostrychninesulphonic acid I. The authors do not agree with the conclusion that the bromine atom in bromostychnine is attached to a carbon atom of a side-chain (Abstr., 1885, 911; Ciusa and Scagliarina, this vol., i, 583.)

Nitrostrychninesulphonic acid I, $\text{C}_{21}\text{H}_{22}\text{O}_7\text{N}_3\text{S}$, prepared by boiling the base for a short time with 5*N*-nitric acid in the presence of carbamide, crystallises in massive, straw-yellow prisms, which are not molten at 300°. It has $[\alpha]_D^{20} = -364^\circ$ in dilute sodium hydroxide solution. The corresponding amino-acid, $\text{C}_{21}\text{H}_{23}\text{O}_5\text{N}_3\text{S}$, crystallises in colourless needles or thin plates, and decomposes at 270°. Its solution in sodium hydroxide has $[\alpha]_D^{20} = -244.8^\circ$. The *hydrochloride*,

and sulphate are readily soluble, but the nitrate sparingly soluble.

Azostychninesulphonic acid I, $\text{C}_{21}\text{H}_{22}\text{O}_5\text{N}_6\text{S}_2$, crystallises in orange-

yellow plates containing $8\text{H}_2\text{O}$, and when dehydrated under reduced pressure at 80° forms greenish-yellow crystals.

Bromostrychninesulphonic acid I., $\text{C}_{21}\text{H}_{21}\text{O}_5\text{N}_2\text{SBr}$, prepared by the action of a solution of bromine in hydrobromic acid (D 1.46) on the sulphonic acid, forms colourless, rectangular prisms or plates. In aqueous sodium hydroxide solution it has $[\alpha]_D^{20} - 233.6^\circ$.

Bromonitrostrychninesulphonic acid, $\text{C}_{21}\text{H}_{20}\text{O}_7\text{N}_3\text{SBr}\cdot\text{H}_2\text{O}$, formed by the action of bromine on the nitro-acid, crystallises in broad, yellow needles. Care is required in the preparation, as there is a tendency for the bromine to replace the nitro-group.

Chlorostrychninesulphonic acid I., $\text{C}_{21}\text{H}_{21}\text{O}_5\text{N}_2\text{SCl}\cdot\text{H}_2\text{O}$, is formed by the action of chlorine water and concentrated hydrochloric acid on the sulphonic acid at 0° , and crystallises in massive, six-sided prisms with $[\alpha]_D^{20} - 239.9^\circ$. *Dichlorostrychninesulphonic acid I.*,

$\text{C}_{21}\text{H}_{20}\text{O}_5\text{N}_2\text{SCl}_2\cdot\text{H}_2\text{O}$,
forms six-sided plates and has $[\alpha]_D^{20} - 155.9^\circ$.

Chloride of isostrychninesulphonic anhydride, $\text{C}_{21}\text{H}_{21}\text{O}_4\text{N}_2\text{SCl}\cdot 2\text{H}_2\text{O}$, obtained by the action of concentrated hydrochloric acid on the sulphonic acid at $130\text{--}135^\circ$, crystallises in long prisms, loses its water of hydration at 80° under reduced pressure, and gives Otto's strychnine reaction. *isostrychninesulphonic acid I.*, $\text{C}_{21}\text{H}_{23}\text{O}_5\text{N}_2\text{S}\cdot 2\text{H}_2\text{O}$, has $[\alpha]_D^{20} - 242^\circ$ to -244° in alkaline solution, and is not so readily soluble in water as the isomeric acid. The *chloride of isonitrostrychninesulphonic anhydride I.*, $\text{C}_{21}\text{H}_{20}\text{O}_6\text{N}_3\text{SCl}$, crystallises in irregular plates, practically insoluble in water, and *isonitrostrychninesulphonic acid I.*, $\text{C}_{21}\text{H}_{21}\text{O}_7\text{N}_3\text{S}$, has $[\alpha]_D^{20} - 285.9^\circ$, and its solubility in water is 1 in 2000.

When oxidised with hydrogen peroxide, the sulphonic acid I. yields the *amino-oxide*, $\text{C}_{21}\text{H}_{22}\text{O}_6\text{N}_2\text{S}_2\cdot 2\text{H}_2\text{O}$, in the form of long, colourless needles, with $[\alpha]_D^{20} - 161.8^\circ$ in alkaline solution. It is readily reduced by sulphurous acid. The nitrosulphonic acid I. when oxidised in a similar manner yields the *amino-oxide*, $\text{C}_{21}\text{H}_{21}\text{O}_6\text{N}_3\text{S}$, as massive, yellow needles, with $[\alpha]_D^{20} - 240^\circ$.

Bromostrychninonic acid, $\text{C}_{21}\text{H}_{19}\text{O}_6\text{N}_2\text{Br}$, prepared by oxidising bromostrychnine (Beckurts, Abstr., 1890, 1329) in acetone solution with permanganate, crystallises in twinned needles, is hydrated, has m. p. $274\text{--}276^\circ$ (corr.), and $[\alpha]_D^{20} - 54.8^\circ$ in alkaline solution. J. J. S.

Strychnine Alkaloids. X. Reactions of Strychninonic Acid and of Strychninolone. HERMANN LEUCHS and PAUL REICH (*Ber.*, 1910, 43, 2417—2429. Compare Abstr., 1908, i, 564; 1909, i, 602). —Attempts have been made to prove the presence of two carboxylic groups in strychninonic acid. With methyl alcohol and hydrogen chloride a monomethyl ester is formed, and ultimately products containing chlorine, and these with sodium carbonate yield two substances, one containing two carbomethoxy-groups and the other a carboxylic and a carbomethoxy-group, but both derived from the original acid plus a molecule of water, so that it is possible that the second carboxylic group is formed by the addition of water to an $\text{N}\cdot\text{CO}$ group in the original strychninonic acid molecule.

The acid reacts with dilute hydrochloric acid, yielding two hydrates containing respectively one and two molecules of water. The former

is regarded as an imino-acid formed by the rupture of the $\begin{smallmatrix} \text{N} \\ \text{CO} \end{smallmatrix}$ group. In the other, the second molecule of water is probably attached to the carbonyl group.

An anilide is formed when the acid is boiled with aniline, and hence the carbonyl group is in all probability not in the α -position with respect to the carboxylic group.

Methyl strychninonate, $\text{C}_{22}\text{H}_{22}\text{O}_6\text{N}_2$, crystallises from methyl alcohol in brilliant prisms, m. p. 247—249°. A *hydrate* of the methyl ester, $\text{C}_{22}\text{H}_{24}\text{O}_7\text{N}_2$, is formed when the solution in methyl alcohol is saturated with hydrogen chloride, and crystallises in rectangular prisms or plates, m. p. 184—186°. It dissolves in both dilute acids and dilute alkalis. The *dimethyl ester hydrate* forms a platinichloride, probably $\text{C}_{46}\text{H}_{64}\text{O}_{14}\text{N}_4\text{PtCl}_6$.

Strychninonic acid hydrate, $\text{C}_{21}\text{H}_{22}\text{O}_7\text{N}_2$, crystallises from water in long needles containing $2\text{H}_2\text{O}$, which it loses at 105°, and then has m. p. 270—275° (decomp.). It has $[\alpha]_D^{20} + 39.6^\circ$. The *dihydrate*,

is less soluble in water, and crystallises at 0° in rectangular prisms; it has m. p. 235—240°. It yields a *sodium salt*, $\text{C}_{21}\text{H}_{22}\text{O}_7\text{N}_2\text{Na}$, which forms small prisms, m. p. 250—255° (decomp.).

Nitrostrychninonic acid, $\text{C}_{21}\text{H}_{19}\text{O}_8\text{N}_3$, obtained by the action of 5*N*-nitric acid and carbamide on strychninonic acid and extracting with chloroform, crystallises from glacial acetic acid in six-sided plates, m. p. 264—266° (decomp.). Yield, 20—25%.

Strychninonanilide, $\text{C}_{27}\text{H}_{26}\text{O}_5\text{N}_3$, crystallises from 75% acetic acid in short, massive prisms, m. p. 255° (decomp.).

Strychninolone contains a hydroxyl group, and yields an *acetyl derivative*, $\text{C}_{21}\text{H}_{20}\text{O}_4\text{N}_2$, which crystallises from methyl alcohol in brilliant prisms, m. p. 126—128° (decomp.). With a chloroform solution of phosphoryl chloride, strychninolone yields *strychninolone chloride hydrate*, $\text{C}_{19}\text{H}_{19}\text{O}_5\text{N}_2\text{Cl}$, which crystallises from absolute alcohol in slender needles, m. p. 236°.

When heated with concentrated hydrochloric acid at 100°, strychninolone yields two hydrates. The *hydrochloride of hydrate I*,

crystallises from hot water in glistening prisms, m. p. 305—310° (decomp.). The hydrate itself is a syrup. The *hydrate II*,

crystallises from water in thick prisms or long needles, m. p. 239—240°. Both hydrates have the properties of amino-acids.

J. J. S.

Glutamic Acid and Pyrrolidonecarboxylic Acid. Engl. ABDERHALDEN and KARL KAUTZSCH (*Zeitsch. physiol. Chem.*, 1910, 68, 487—503. Compare this vol., i, 230).—Owing to the ease with which it changes into glutamic acid, the formation of pyrrolidonecarboxylic (not pyrrolidinecarboxylic, *loc. cit.*) acid has not yet been detected amongst the products of the hydrolysis of albumins by the ordinary processes. With this end in view, the authors have instituted further experiments for the separation of pyrrolidonecarboxylic acid from

other amino-acids, especially from glutamic acid. Utilising the amino-group in the latter, the authors have converted it by means of ethyl chloroformate into *carbethoxyglutamic acid*,

which forms a *barium salt*, $\text{C}_8\text{H}_{11}\text{O}_6\text{NBa}_2\cdot\text{H}_2\text{O}$, a *silver salt*,

and an amorphous, green *copper salt*, $\text{C}_8\text{H}_{11}\text{O}_6\text{NCu}$, which is much less soluble in water than copper pyrrolidonecarboxylate. It is noteworthy that glutamic acid, owing to the influence of the amino-group on the neighbouring carboxyl, behaves generally like a monobasic acid (*loc. cit.*), whereas carbethoxyglutamic acid exerts its dibasic function in salt formation. The separation of glutamic acid from pyrrolidonecarboxylic acid is very conveniently effected by Siegfried's carbanimino-reaction (Abstr., 1906, i, 144).

The formation of pyrrolidonecarboxylic acid from glutamic acid by heating has been examined more thoroughly. At $150-160^\circ$, *d*-glutamic acid yields a product, m. p. about 145° , $[\alpha]_D -10.06^\circ$ in water, from which *l*-pyrrolidonecarboxylic acid, $[\alpha]_D -11.5^\circ$, can be separated by fractional crystallisation from water. At $180-220^\circ$, *d*-glutamic acid yields chiefly *i*-pyrrolidonecarboxylic acid. At $160-170^\circ$, under conditions as yet unknown, *d*-glutamic acid yields occasionally a small quantity of a substance, $\text{C}_5\text{H}_7\text{O}_3\text{N}$, m. p. $180-182^\circ$, $[\alpha]_D +4.24^\circ$ in water. A *l*-pyrrolidonecarboxylic acid, obtained from *d*-glutamic acid and having $[\alpha]_D -11.27^\circ$ in water, had $[\alpha]_D +4.24^\circ$ in methyl alcohol and $+3.75^\circ$ in ethyl alcohol. A *l*-pyrrolidonecarboxylic acid, (therefore containing about 19% of the inactive acid), was treated with 5*N* hydrochloric acid for six to seven days, whereby *d*-glutamic acid, $[\alpha]_D +23.3^\circ$, was obtained; pure *d*-glutamic acid in 5*N*-hydrochloric acid has $[\alpha]_D +28.88^\circ$. Under similar conditions, *i*-pyrrolidonecarboxylic acid yielded *i*-glutamic acid hydrochloride, m. p. 200° .

Silver glutamate, $\text{C}_5\text{H}_7\text{O}_4\text{NAg}_2$, *basic zinc glutamate*,

and the *lead*, *copper*, and *silver salts* of pyrrolidonecarboxylic acid are described.

G. S.

Existence of Liquid Racemic Compounds. ALBERT LADENBURG and SOBECKI (*Ber.*, 1910, 43, 2374-2380).—The freezing-point curve of mixtures of *d*- and *l*-pipercolines has been determined; the curve shows two eutectics at -6.65° and a maximum at -4.9° , corresponding with the formation of a definite racemic compound.

The solubility of dipentene in 98.99% acetic acid at 12° has been determined, the method of estimation being conversion into bromide. The saturated solution of dipentene in acetic acid when shaken with 10% of d-limonene still shows the same amount of hydrocarbon in solution, although the solution has become strongly dextrorotatory. The two results are contradictory, but the authors conclude that dipentene is a mixture and not a definite compound.

Experiments have also been made on the solubility of *dl*-ethylpiperidine and mixture of *dl* with *l*-ethylpiperidine in water at 24.95° and 21.95° . The concentration of the solutions was determined by means of standard hydrochloric acid, using *o*-nitrophenol as

indicator. The results show that the solubility is not affected by the presence of an excess of one of the active constituents. The solution, however, was levorotatory.

Pure *l*- α -ethylpiperidine is best prepared by resolution of the *dl*-base with Reychler's acid. The *l*-base has D_{25}^D 0.8451, and $[\alpha]_D^{25}$ -21.3°.

Details of the preparation of the *dl*-base are given. J. J. S.

Anomalous Products of Benzoylation. GUSTAV HELLER and WALTER TISCHNER (*Ber.*, 1910, 43, 2574—2581).—After quoting several instances in which anomalous products are obtained by benzoylation in pyridine or quinoline (Heller and Kiesselmann, *Abstr.*, 1902, i, 779; Heller, *Abstr.*, 1903, i, 827; Scholl and Berblinger, *Abstr.*, 1907, i, 257), the authors describe the following benzoylated substances containing pyridine. By treating a cold pyridine solution of *p*-aminobenzoic acid with benzoyl chloride, the substance, $2C_{14}H_{11}O_3N_3C_6NH_5$, m. p. above 340°, is obtained, which crystallises in slender needles, forms sparingly soluble sodium and potassium salts, and retains the pyridine even after steam has been passed through its strongly alkaline solution; the pyridine is removed, however, by hydrochloric acid at 170°, aniline and *p*-aminobenzoic acid being formed. Benzoylation in quinoline or dimethylaniline yields only the normal product. In a similar way, *m*-aminobenzoic acid and *p*-aminophenylacetic acid yield respectively the substances, $2C_{14}H_{11}O_3N_3C_6NH_5$ and

(which are precipitated by the addition of dilute hydrochloric acid), together with the normal products of benzoylation. When *p*-benzoylaminobenzoic acid is heated with acetic anhydride, an isomeride separates on cooling in tufts of colourless needles; it contains $\frac{1}{2}Ac_2O$, which is removed at 150°, but not by sodium carbonate solution, and has m. p. 240° (softening at 150—155° and resolidifying). The dried substance sinters at 265°, resolidifies, and then slowly decomposes at a much higher temperature; it is not immediately soluble in boiling sodium carbonate, and only dissolves slowly in warm sodium hydroxide, the solution yielding *p*-benzoylaminobenzoic acid by acidification. On account of these properties, the isomeride receives the constitution $C_6H_4 \begin{smallmatrix} \text{NH}_2Bz \\ \text{CO} \end{smallmatrix} O$, and is called *p*-benzoylaminobenzoic acid cycloid. When boiled with acetic anhydride, *p*-acetylaminobenzoic acid yields *p*-diacetylaminobenzoic anhydride, $(NAc_2 \cdot C_6H_4 \cdot CO)_2O$, m. p. 253—254°.

The paper also contains a reply to the statements of Bamberger (*Abstr.*, 1909, i, 509) and of Mohr (this vol., i, 116) that acetyl-anthranil contains the 1:3-oxazine ring. C. S.

Constitution of Benzoylanthranil. OTTO MUMM and RUGO HESSE (*Ber.*, 1910, 43, 2505—2511).—Two formulae have been proposed for benzoylanthranil: that of Friedländer and Wiegand (I), and that of Angeli and Angelico (II), of which the latter is considered the

more probable. No direct proof of its validity, however, has yet been given, but such is now afforded by the interaction of anthranilic acid with benzanilideiminochloride to form a ring system. From the intermediate product of the reaction, water must be eliminated if the Friedländer-Wiegand formula is correct, and aniline must be eliminated if the Angeli-Angelico formula is the true one. Experiments in absolute ethereal solution, with or without pyridine, proved that aniline is eliminated and benzoylanthranil formed.

Diphenylquinazoline, $C_6H_4 \begin{smallmatrix} \swarrow N \cdot CPh \\ \searrow CO \cdot NPh \end{smallmatrix}$, could not be obtained by the action of benzanilide chloride on anthranil, but it was obtained by shaking sodium anthranilate in aqueous solution with benzanilideiminochloride in ether. It crystallises in prisms, m. p. 158–159°, and has faintly basic properties, the *hydrochloride* having m. p. 172°. E. F. A.

Preparation of Substituted Indoles by the Catalytic Decomposition of Arylhydrazones. ALEXANDER E. ARBUSOFF and W. M. TICHWINSKY (*Ber.*, 1910, 43, 2301–2303).—The phenyl- and tolylhydrazones of the lower aliphatic aldehydes and ketones yield substituted indoles when heated with small amounts (0.1 gram) of cuprous chloride at 180–230°. The bases can be isolated by subjecting the crude products to fractional distillation under reduced pressure.

2:3-Dimethylindole, 3-methylindole, and 3:5-dimethylindole have been prepared from methyl ethyl ketone phenylhydrazone, propionaldehyde-phenylhydrazone, and propionaldehyde-*p*-tolylhydrazone respectively.

Zinc chloride and platinous chloride can be used instead of cuprous chloride. J. J. S.

Syntheses with *o*-Xylylene Bromide. MAX SCHOLTZ and R. WOLFRUM (*Ber.*, 1910, 43, 2304–2318. Compare Scholtz, *Abstr.*, 1898, i, 305, 383, 471, 565, 567).—*tert*-Butylamine reacts with *o*-xylylene bromide in the same manner as other aliphatic primary amines, no steric hindrance is observable, and the product is *tert*-butyldihydroisindole, $C_6H_4 \begin{smallmatrix} \swarrow CH_2 \\ \searrow CH_2 \end{smallmatrix} N \cdot CMe_3$, which crystallises from ethyl alcohol in glistening plates, m. p. 42° and b. p. 125–130°/13 mm. Its *methiodide*, $C_{13}H_{20}NI$, forms colourless crystals, m. p. 221°.

p-Aminoacetophenone (3 mols.) also condenses with *o*-xylylene bromide (1 mol.), yielding *p*-acetylphenyldihydroisindole,

in the form of glistening plates, m. p. 197°. This compound condenses with aldehydes in the presence of alkalis in much the same manner as *p*-aminoacetophenone itself (Scholtz and Huber, *Abstr.*, 1904, i, 253).

The *benzylidene* derivative, $C_6H_5 \cdot N \cdot C_6H_4 \cdot CO \cdot CH \cdot CHPh$, crystallises from alcohol in glistening, yellow plates, m. p. 202°; the *cinnamylidene* derivative, $C_6H_5 \cdot N \cdot C_6H_4 \cdot CO \cdot CH \cdot CH \cdot CH \cdot CHPh$, crystallises from

acetone in slender, orange-coloured needles, m. p. 187°; the *nitrobenzylidene* derivative, $C_{23}H_{18}O_3N_2$, forms a pale yellow, crystalline powder, m. p. 238°. 2-*p*-*Dimethylamino-p*-cinnamoylphenyldihydroisindole, $C_6H_5 \cdot N \cdot C_6H_4 \cdot CO \cdot CH : CH \cdot C_6H_4 \cdot NMe_2$, crystallises from pyridine in golden-yellow plates, m. p. 196°.

At 100° 2-phenyldihydroisindole combines readily with methyl iodide, yielding the *methiodide*, $C_8H_8 \cdot NPh \cdot MeI$, which forms colourless plates, m. p. 177°. 2-Phenyldihydroisindole condenses readily with aldehydes, especially in the presence of concentrated hydrochloric acid, yielding derivatives of diphenylmethane, or, in the case of aromatic aldehydes, derivatives of triphenylmethane. The condensation takes place in the para-position with respect to the nitrogen atom, as *p*-tolyldihydroisindole does not react with aldehydes. Formaldehyde reacts without the aid of a condensing reagent, yielding *biszylyleneaminodiphenylmethane*, $CH_2(C_6H_4 \cdot N : C_6H_5)_2$, which forms slender needles, m. p. 308–309°. *Biszylyleneaminotriphenylmethane*, $CHPh(C_6H_4 \cdot N : C_6H_5)_3$, separates from a mixture of pyridine and alcohol in colourless, felted needles, m. p. 265°. *Biszylyleneaminodimethylaminotriphenylmethane*, $NMe_2 \cdot C_6H_4 \cdot CH(C_6H_4 \cdot N : C_6H_5)_2$, crystallises from pyridine in colourless needles, m. p. 185°. *Biszylyleneaminodiphenylstyrylmethane*, $CHPh \cdot CH : CH(C_6H_4 \cdot N : C_6H_5)_2$, forms a yellow, crystalline powder, which is not molten at 300°. *Biszylyleneamino-di-m-tolylmethane*, $CH_2(C_6H_3Me \cdot N : C_6H_5)_2$, obtained from *m*-tolyldihydroisindole, crystallises from pyridine in colourless needles, m. p. 255°.

Scholtz and Jaross (Abstr., 1901, i, 485) have shown that secondary 1:4-diamines condense with alcoholic solutions of aldehydes without the use of a condensing agent; an exception to this rule is xylylene-di-*o*-toluidine, which does not react. It is now shown that this base will condense with aldehydes in the presence of concentrated hydrochloric acid. With formaldehyde, it yields *methylene-di-o-tolyl-o-xylylenediamine*, $C_6H_4 \begin{smallmatrix} < CH_2 \cdot N(C_6H_4Me) \\ < CH_2 \cdot N(C_6H_4Me) \end{smallmatrix} > CH_2$, as glistening prisms, m. p. 139°, and with benzaldehyde, *benzylidene-di-o-tolyl-o-xylylenediamine*, $C_6H_4 \begin{smallmatrix} < CH_2 \cdot N(C_6H_4Me) \\ < CHPh \cdot N(C_6H_4Me) \end{smallmatrix} > CHPh$, m. p. 180°.

Methylamine reacts with xylylenepiperidonium bromide at 200° in much the same manner as ammonia (Abstr., 1898, i, 567), yielding *pentamethylenemethylxylylenediamine*,

This is a colourless liquid, b. p. 160–165°/15 mm., and yields a *benzenesulphonyl* derivative, $C_{14}H_{21}N_5 \cdot SO_2Ph$, m. p. 87°. When distilled, the methyl derivative yields 2-methyldihydroisindole (Fränkel, Abstr., 1901, i, 45).

The products obtained by the condensation of xylylenepiperidonium bromide with aliphatic secondary amines, and previously represented as $NR_2 \cdot CH_2 \cdot C_6H_4 \cdot CH_2 \cdot N : C_6H_{10}$, are undoubtedly cyclic compounds of the type $C_6H_4 \begin{smallmatrix} < CH_2 \cdot NR \cdot CH_2 \cdot CH_2 \\ < CH_2 \cdot NR \cdot CH_2 \cdot CH_2 \end{smallmatrix} > CH_2$. Aromatic primary amines react with xylylenepiperidonium bromide in different ways

according to the nature of the amine. With aniline at 200°, piperidine and phenylidihydroisindole are formed; *p*-toluidine reacts in a similar manner, but *o*-toluidine does not yield an isindole derivative. The reaction probably consists of a rupture of the original ring, the formation of an eleven-membered ring, and the splitting up of this into the two compounds mentioned.

Dixylyleneammonium bromide (Scholtz, Abstr., 1891, 1353) when heated with piperidine and water at 200° yields a ditortary base,

xylylenepentamethylenexylylenediamine, h. p. 240–245°.

o-Xylylene bromide and tetrahydroquinoline condense in the usual manner, yielding *o*-xylylenetetrahydroquinolinium bromide,

which is a syrup; the corresponding *iodide*, $\text{C}_{17}\text{H}_{18}\text{NI}$, forms colourless needles, m. p. 238°, and the *picrate*, $\text{C}_{17}\text{H}_{13}\text{N} \cdot \text{O} \cdot \text{C}_6\text{H}_2(\text{NO}_2)_3$, yellow needles, m. p. 165°.

Dibenzyl-o-xylyleneammonium bromide, $\text{C}_8\text{H}_8 \cdot \text{NBr}(\text{CH}_2\text{Ph})_2$, prepared from *o*-xylylene bromide and dibenzylamine in chloroform solution, crystallises in snow-white plates, m. p. 188°, and when heated with ammonia at 200° yields *dibenzyl-o-xylylenediamine*,

the *hydrochloride* of which has m. p. 251°.

o-Xylylenediisocamylammonium bromide is an oil; the *iodide*, $\text{C}_{15}\text{H}_{20}\text{NI}$, crystallises from water, and has m. p. 139°. The bromide when heated with ammonia at 200° yields *o*-xylylenediisocamylamine, $\text{C}_6\text{H}_4(\text{CH}_2 \cdot \text{NH} \cdot \text{C}_5\text{H}_{11})_2$, a colourless oil with b. p. 210°/12 mm.

Dibenzylpiperidonium bromide, $\text{C}_8\text{H}_{10} \cdot \text{NBr}(\text{CH}_2\text{Ph})_2$, prepared by the action of dibenzylamine on *ac*-dibromopentane, crystallises in colourless plates, m. p. 253°, and when heated with ammonia at 200° yields benzylamine, dibenzylamine, and benzylpiperidine. *o*-Xylylenedipropylammonium bromide, $\text{C}_8\text{H}_8 \cdot \text{NBr}(\text{C}_3\text{H}_7)_2$, crystallises in colourless plates, m. p. 107°, and when heated with ammonia at 200° yields propyl bromide and 2-propyldihydroisindole. The latter is a colourless oil, b. p. 230–240°, and forms a *methiodide*, $\text{C}_{11}\text{H}_{15}\text{N} \cdot \text{MeI}$, m. p. 150°. The *platinichloride*, $(\text{C}_{11}\text{H}_{15}\text{N})_2\text{H}_2\text{PtCl}_6$, forms a reddish-yellow powder, m. p. 192°. The decomposition of the dipropyl derivative is thus analogous to that of the diethyl salt (Abstr., 1898, i, 568).

2 *Amylenedihydroisindole*, $\text{C}_8\text{NH}_8 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH} \cdot \text{CH}_2$, obtained by treating xylylenepiperidonium bromide with moist silver oxide evaporating to a syrup, and distilling, has h. p. 140–150°/12 mm. Its *methiodide* is also oily.

J. J. S.

New Method for the Synthesis of *iso*Quinoline Bases. AMÉ PICTET and ALFONS GAMS (*Ber.*, 1910, 43, 2384–2391. Compare Abstr., 1909, i, 671).—Acylated carbinols of the type

where R = methyl, phenyl or benzyl, readily undergo condensation when heated with phosphoric oxide and xylene, yielding 1-substituted

isoquinolines. Phenylformylaminomethylcarbinol reacts in a similar manner, yielding *isoquinoline*, and this is the most convenient synthetic method for the preparation of the base.

Phenylphenacetylaminomethylcarbinol,
 $\text{OH}\cdot\text{CHPh}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{Ph}$,

obtained by reducing ω -phenylacetylaminoacetophenone (Robinson, Trans., 1909, 95, 2167) with sodium amalgam, alcohol, and acetic acid, crystallises from water in slender needles, m. p. 123° .

Phenylbenzoylaminoethylcarbinol (Kolshorn, Abstr., 1904, i, 675) is prepared most readily by reducing benzoylaminoacetophenone (Robinson, loc. cit.). *Phenylacetylaminomethylcarbinol*,
 $\text{OH}\cdot\text{CHPh}\cdot\text{CH}_2\cdot\text{NHAc}$,

crystallises from benzene in colourless needles, m. p. 104° . 1-Benzyl-*isoquinoline* forms colourless needles, m. p. 56° . 1-*Phenylisoquinoline*, $\text{C}_{15}\text{H}_{11}\text{N}$, crystallises from dilute alcohol in colourless needles, m. p. 93° , b. p. $298^\circ/729$ mm. The *hydrochloride* has m. p. $235\text{--}236^\circ$; the *picrate*, m. p. $164\text{--}5^\circ$, and the *platinichloride* forms red needles, m. p. 242° (decomp.).

1-*Methylisoquinoline*, $\text{C}_{10}\text{H}_9\text{N}$, is a colourless oil, b. p. $243\text{--}245^\circ/728$ mm. The *hydrochloride* forms colourless needles, m. p. about 170° ; the *sulphate* forms colourless prisms, m. p. 245° ; the *picrate* has m. p. $206\text{--}208^\circ$; the *dichromate* forms red prisms, sparingly soluble in water, and decomposes at about 150° ; the *platinichloride*,
 $2\text{C}_{10}\text{H}_9\text{N}\cdot\text{H}_2\text{PtCl}_6\cdot 2\text{H}_2\text{O}$,

forms reddish-yellow prisms, and melts at $201\text{--}5^\circ$ when anhydrous. The base is probably identical with the two methyl-*isoquinolines* described in Beilstein.

ω -*Formylaminoacetophenone*, $\text{COPh}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CHO}$, prepared by the action of crystallised formic acid on ω -aminoacetophenone hydrochloride, crystallises from a mixture of benzene and light petroleum in large, flat prisms, m. p. $70\text{--}71^\circ$, and when reduced with sodium amalgam, alcohol, and formic acid yields *phenylformylaminomethylcarbinol*, $\text{OH}\cdot\text{CHPh}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CHO}$, as a reddish-brown, crystalline mass. J. J. S.

Preparation of a Dihydroxycarbazoledisulphonic Acid. FARBENFABRIKEN VORM. FRIEDRICH BAYER & Co. (D.R.P. 224953).—The product obtained by fusing carbazoledisulphonic acid with an alkali hydroxide has been described (Schultz and Hauenstein, Abstr., 1907, i, 1074), but whether the product was a dihydroxy- or a hydroxycarbazolesulphonic acid is not definitely stated.

When carbazole is treated with fuming sulphuric acid (five parts) at a temperature not exceeding 40° , and then slowly heated to 100° , *disulphonation* takes place; if this mixture is further treated with two parts of sulphuric acid (containing 65% SO_3) and kept at $90\text{--}100^\circ$ until the product ceases to be separable on the addition of salt, *carbazoletetrasulphonic acid* is obtained, and finally isolated by evaporation in the form of its *potassium salt*.

Dihydroxycarbazoledisulphonic acid is prepared from the foregoing acid by fusion with alkali hydroxide at a temperature of $240\text{--}300^\circ$.

the potassium salt forms colourless needles containing $4\text{H}_2\text{O}$, and shows a green fluorescence on addition of ammonium hydroxide.

The free acid can be isolated from its barium salt.

F. M. G. M.

[Preparation of *N*-Alkyl- and of *N*-Aryl-carbazoles and their Indophenol Derivatives.] LEOPOLD CASSELLA & Co. (D.R.P. 224951).—The *N*-alkyl-carbazoles have been previously described; it is now found that *N*-aryl-carbazoles can be prepared in analogous manner, and that they likewise, when heated with polysulphides, yield valuable dyes.

3-Benzylcarbazole, colourless needles, m. p. 118—120°, is prepared by the action of benzyl chloride on potassium carbazole at high temperatures or under pressure.

3-Phenylcarbazole is obtained by heating potassium carbazole with bromobenzene in the presence of copper powder under pressure at a temperature of 180—220°; it forms colourless needles, m. p. 82—84°.

9-*p*-Tolylsulphonylcarbazole, pale yellow needles, m. p. 127—128°, is prepared from potassium carbazole and *p*-toluenesulphonyl chloride. These substances combine with *p*-nitrosophenol, yielding dark blue powders, which on reduction form greyish-white, crystalline leuco-compounds.

F. M. G. M.

Condensation Products from Salicylidene- and Hydrocyano-salicylidene-aniline (Anilino-*o*-hydroxyphenylacetoneitrile). (GEORG RÖHDE and G. SCHARTEL (*Ber.*, 1910, 43, 2274—2286).—Miller and Plüchl (*Ber.*, 1896, 27, 1730; 1898, 29, 2699) have shown that Schiff's bases do not undergo the benzoin condensation with potassium cyanide. The product obtained by Schwab (*Abstr.*, 1901, i, 380) by condensing *o*-hydroxybenzylideneaniline with an alcoholic solution of potassium cyanide is shown to be 4-cyano-3-phenyl-2-*o*-hydroxyphenyl-3:4-dihydro-1:3-benzoxazine, $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{O} \\ \diagup \quad \diagdown \\ \text{CH} \cdot \text{C}_6\text{H}_4 \cdot \text{OH} \\ \diagdown \quad \diagup \\ \text{CH}(\text{CN}) \cdot \text{NPh} \end{smallmatrix}$, and not

to have the constitution ascribed to it by Schwab. The product is prepared most readily by shaking vigorously for three hours an alcoholic solution of aniline (1 mol.) and salicylaldehyde (2 mols.) with an alcoholic solution of potassium cyanide (1 mol.). When its ethereal solution is hydrolysed with concentrated hydrochloric acid, the products are salicylaldehyde and the acid amide hydrocyanosalicylideneaniline, anilino-*o*-hydroxyphenylacetamide, $\text{OH} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}(\text{NHPh}) \cdot \text{CO} \cdot \text{NH}_2$, which yields a hydrochloride, $\text{C}_{14}\text{H}_{14}\text{O}_2\text{N}_2 \cdot \text{HCl}$, crystallising from alcohol in colourless needles, m. p. 183°. The amide crystallises from benzene in colourless needles containing benzene and melting at 63°; when further heated, it gives up benzene, solidifies, and then has m. p. 126°. The same amide can be prepared by adding Miller and Plüchl's hydrocyanosalicylideneaniline (anilino-*o*-hydroxyphenylacetoneitrile) to concentrated hydrochloric acid.

Schwab's condensation product can be synthesised by shaking an alcoholic solution of hydrocyanosalicylideneaniline with salicylaldehyde and potassium hydroxide dissolved in a little water. The following derivatives are described: Sodium salt, $\text{C}_{14}\text{H}_{13}\text{O}_2\text{N}_2\text{Na}$, yellow,

glistening powder, m. p. 249°, obtained by shaking an ethereal solution of the 1:3-benzoxazine with 10% sodium hydroxide solution; *benzoyl* derivative, $C_{26}H_{20}O_8N_2$, yellow crystals, m. p. 188°; *benzenesulphonyl* derivative, $C_{27}H_{20}O_9N_2S$, glistening needles from alcohol, m. p. 162°.

Hydrocyanosalicylideneaniline and benzaldehyde undergo condensation in the presence of potassium hydroxide, yielding 4-cyano-2:3-diphenyl-2:4-dihydro-1:3-benzoxazine, $C_{14}H_{13}ON_2$, in the form of yellow needles, m. p. 138°.

When molecular quantities of salicylideneaniline and potassium cyanide are condensed, a product, $C_{14}H_{13}ON_2$, is formed, which crystallises from benzene in compact prisms, m. p. 135–137°. The same product is formed by condensing salicylaldehyde and salicylideneaniline with potassium cyanide or salicylideneaniline and hydrocyanosalicylideneaniline with potassium cyanide. It is isomeric with hydrocyanosalicylideneaniline, from which it can be obtained by shaking with potassium cyanide, potassium carbonate, or sodium ethoxide solutions.

A by-product formed in the preparation of the benzoxazine separates as dark red needles from the mother liquors after a time, and can be obtained most readily by boiling an alcoholic solution of aniline, salicylaldehyde, and potassium cyanide for two to three hours. It can be crystallised from pyridine, has m. p. 258°, and is stable towards acids. Its *acetyl* derivative crystallises from alcohol in pale yellow needles, m. p. 195°, and its *benzoyl* derivative in yellowish-brown prisms, m. p. 227°.

J. J. S.

Catalytic Decomposition of Phenylhydrazine by means of Cuprous Halides. ALEXANDER E. ARBUSOFF and W. M. TICHWINSKY (*Ber.*, 1910, 43, 2295–2296. Compare Struthers, *Proc.*, 1905, 21, 95).—At 150° phenylhydrazine reacts with cuprous halides according to the equation: $3NHPh \cdot NH_2 + CuCl = 3NH_2Ph + N_2 + NH_3 + CuCl$. The reaction is preceded by the formation of an additive compound, for example, the compound, $2NHPh \cdot NiCl_2 \cdot CuI$, has been isolated as colourless prisms, which begin to decompose at 150°.

The rate of decomposition with the different halides has been determined; the reaction proceeds most rapidly with the chloride, and least readily with the iodide. If sufficient care is not taken, the reaction with cuprous chloride may become explosive. J. J. S.

Nitrosophenylhydrazine. EUGEN BAMBERGER and H. HAUSER (*Annalen*, 1910, 375, 316–333).—The preparation and properties of nitrosophenylhydrazine are described, and also many of its reactions, chiefly in the form of test-tube experiments. It acts as a pronounced reducing agent towards mercuric nitrate, yellow mercuric oxide, silver nitrate, and calcium hypochlorite, being itself oxidised mainly to nitrobenzene (detected by its odour). Its alcoholic solution, as concentrated as possible, yields at -12° to -15° with a cold saturated alcoholic solution of cupric acetate, *copper nitrosophenylhydrazine*, $Cu(C_6H_5N_2O)_2$, which forms copper-red leaflets with a bronze lustre, is extremely explosive, and inflames in contact with concentrated sulphuric or nitric acid. The solution of the metallic derivative in

acetone gives, almost immediately, a precipitate of copper sulphide with hydrogen sulphide; the reaction, however, is not regarded as ionic, the substance being probably an internally complex salt. When the red copper derivative is treated with acetic acid containing a little water (the absence of water prevents the reaction), nitrogen is evolved and pale grey needles of copper nitrosophenylhydroxylamine are produced. This copper derivative is more conveniently obtained by treating an alcoholic solution of nitrosophenylhydrazine at 0° with a solution (saturated at 5°) of copper acetate in glacial acetic acid (the reaction fails in the presence of 13–15% of water), or by adding nitrosophenylhydrazine to ammoniacal copper hydroxide at -16°. This indirect conversion of nitrosophenylhydrazine into nitrosophenylhydroxylamine is not a case of simple hydrolysis: $\text{NH}_2\cdot\text{NPh}\cdot\text{NO} + \text{H}_2\text{O} = \text{OH}\cdot\text{NPh}\cdot\text{NO} + \text{NH}_3$, since it is not appreciably brought about by alkaline reagents, but is probably due to oxidation by the copper oxide: $\text{NH}_2\cdot\text{NPh}\cdot\text{NO} + \text{O} \rightarrow \text{OH}\cdot\text{NPh}\cdot\text{NO} + \text{N}_2$.

The paper closes with some adverse criticisms of the symmetrical formula, $\text{NPh}\cdot\text{NH}\cdot\text{NO}$, suggested by Thiele for nitrosophenylhydrazine in consequence of its decomposition into aniline and nitrous oxide; in the authors' opinion nitrosophenylhydrazine, like nitrosophenylhydroxylamine (Abstr., 1909, i, 977), is tautomeric:

its compounds with heavy metals being derived from either of the latter formulae. C. S.

Constitution of Nitrosophenylhydrazine. JOHANNES THIELE and KARL SIEGLITZ (*Annalen*, 1910, 375, 334–335).—The suggestion advanced by Thiele (Abstr., 1908, i, 927), that nitrosophenylhydrazine has the constitution $\text{NPh}\cdot\text{NH}\cdot\text{NO}$ has been withdrawn, because benzoylnitrosophenylhydrazine, obtained by the benzoylation of nitrosophenylhydrazine, is converted by stannous chloride and hydrochloric acid into *s*-benzoylphenylhydrazine, from which the benzoylnitrosophenylhydrazine is regenerated by sodium nitrite and acetic acid.

C. S.

α -Acylated Phenylhydrazines. OSKAR WIDMANN (*Ber.*, 1910, 43, 2595).—The author's method of preparing α -acylated phenylhydrazines (Abstr., 1893, i, 411; 1894, i, 57, 512; 1895, i, 31) has been overlooked by Lockemann (this vol., i, 636).

C. S.

Influence of the Halogens on Phototropy in Hydrazones. F. GRAZIANI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 190–193. Compare this vol., i, 509).—Some hydrazones derived from *p*-bromophenylhydrazine have been prepared to ascertain if the lack of phototropy in certain chloroaniline derivatives (compare Senior and Shepherd, *Trans.*, 1909, 95, 1943) is due to the presence of the halogen. Of the eight hydrazones examined, four are more or less phototropic, but much less so than the *p*-tolylhydrazones.

Benzaldehyde-*p*-bromophenylhydrazone has m. p. 129° (Biltz and Sieden, Abstr., 1903, i, 120, gave 127.5°), and is phototropic.

Anisaldehyde-*p*-bromophenylhydrazone, m. p. 150° (Ott, Abstr., 1905, i, 376, gave 146—147°), is not phototropic.

Cinnamaldehyde-*p*-bromophenylhydrazone,

crystallises in greenish-yellow, lustrous needles, m. p. 143°, and is phototropic.

Cuminaldehyde-*p*-bromophenylhydrazone,

forms yellow, phototropic needles, m. p. 135°.

Piperonaldehyde-*p*-bromophenylhydrazone,

crystallises in colourless laminae, m. p. 155° (decomp.), and is not phototropic.

p-Tolualdehyde-*p*-bromophenylhydrazone, $\text{C}_6\text{H}_4\text{Br}\cdot\text{N}_2\text{H}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\text{Me}$,

forms small, yellow laminae, m. p. 162° (decomp.), and is not phototropic.

Vanillin-*p*-bromophenylhydrazone is non-phototropic.

Salicylaldehyde-*p*-bromophenylhydrazone has m. p. 171—172° (Biltz and Sieden, *loc. cit.*, gave 175·5°), and is slightly phototropic.

R. V. S.

Relations between Constitution and Phototropy. MAURICE PANO and F. GRAZIANI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 193—196. Compare this vol., i, 509, and preceding abstract).—The authors have obtained a number of hydrazones derived from 1:4:5- and 1:3:5-xylylhydrazines, and have prepared the latter substances for the first time. In agreement with the regularity previously observed, the 1:4:5-derivatives do not exhibit phototropy. Of the four 1:3:5-compounds, one is very feebly phototropic.

1:4:5-Xylylhydrazine hydrochloride has m. p. 209°; Plancher and Caravaggi (Abstr., 1905, i, 158) gave 206°.

Benzaldehyde-1:4:5-xylylhydrazone, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{N}_2\text{H}\cdot\text{CHPh}$, forms small, yellow needles, m. p. 89°.

Anisaldehyde-1:4:5-xylylhydrazone, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{N}_2\text{H}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$, crystallises in small, yellowish-white laminae, m. p. 117°.

Cinnamaldehyde-1:4:5-xylylhydrazone,

forms small, yellow needles, m. p. 121°.

Cuminaldehyde-1:4:5-xylylhydrazone,

crystallises similarly, and has m. p. 85°.

Piperonaldehyde-1:4:5-xylylhydrazone,

crystallises in yellow scales, m. p. 135°.

p-Tolualdehyde-1:4:5-xylylhydrazone, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{N}_2\text{H}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\text{Me}$,

forms minute, pale yellow scales, m. p. 109°.

Vanillin-1:4:5-xylylhydrazone, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{N}_2\text{H}\cdot\text{CH}\cdot\text{C}_6\text{H}_3(\text{OH})\cdot\text{OMe}$,

crystallises in very small, colourless needles, m. p. 158°.

Salicylaldehyde-1:4:5-xylylhydrazone, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{N}_2\text{H}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{OH}$, forms pale yellow scales, m. p. 134°.

1:3:5-Xylylhydrazine hydrochloride was prepared by diazotisation

of the corresponding xylidine. It is very soluble in concentrated hydrochloric acid, and was not obtained in pure condition.

Cinnamaldehyde-1:3:5-xylidylhydrazone forms yellow crystals, m. p. 142—143° (becoming slightly brown), and is phototropic.

p-Tolualdehyde-1:3:5-xylidylhydrazone crystallises in rosettes of yellow needles, m. p. 119°, and is not phototropic.

Piperonaldehyde-1:3:5-xylidylhydrazone forms yellow, non-phototropic needles, m. p. 135—136° (yielding a brown liquid).

Anisaldehyde-1:3:5-xylidylhydrazone crystallises in small, yellow needles, m. p. 144—145° (giving a brown liquid). R. V. S.

Preparation and Phototropy of Some Osazones. MAURICE PADOA and L. SANTI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 302—307. Compare Padoa and Graziani, this vol., i, 509).—Continuing the study of phototropy, the authors have prepared osazones from benzil and piperil with *o*- and *p*-tolyl- and β -naphthyl-hydrazines. Even on combining these results with those of Biltz (Abstr., 1900, ii, 125), no connexion between constitution and phototropy becomes evident. Of the two isomeric forms to be expected, only the β -modification was obtained in every case.

β -Benzil-*p*-tolylsazone, $C_6H_5(C_6H_3(N \cdot NH \cdot C_6H_4Me)_2)_2$, obtained by Pickol's method (Abstr., 1886, 545), is a yellow, crystalline, phototropic substance, m. p. 152°.

β -Piperil-*p*-tolylsazone, $CH_3 \cdot O_2 \cdot C_6H_3 \cdot C \cdot N \cdot NH \cdot C_6H_4Me$
 $CH_3 \cdot O_2 \cdot C_6H_3 \cdot C \cdot N \cdot NH \cdot C_6H_4Me$ similarly prepared, crystallises in small, sulphur-yellow needles, m. p. 215°, and is phototropic.

β -Benzil- β -naphthylsazone, $C_6H_5(C_{10}H_7(N \cdot NH \cdot C_{10}H_7)_2)_2$, obtained by the same method, forms yellow needles, m. p. 211.5°. It is phototropic, and one specimen of it showed phototropic change in either direction with remarkable rapidity, possibly owing to the presence of some impurity catalytically affecting the process.

β -Piperil- β -naphthylsazone, similarly prepared, is a yellow, crystalline, phototropic substance, m. p. 207°.

β -Benzil-*o*-tolylsazone was prepared by Purgotti's method (*Gazzetta*, 1892, 14, ii, 611), and forms a canary-yellow, crystalline, phototropic powder, m. p. 170°.

β -Piperil-*o*-tolylsazone, obtained by the same method, is a yellow, crystalline powder, m. p. 206.5°, and is phototropic. It becomes bright red instantly in sunlight, and may be said to be the most sensitive phototropic substance yet prepared. R. V. S.

Rearrangement in the Quinone Group. ERNST BÖRNSTEIN (*Ber.*, 1910, 43, 2380—2384).—The base obtained by the action of sulphuric acid on *p*-toluidino-*p*-toluquinonetolylimide (Abstr., 1901, i, 376) has the same composition as the original compound, and is regarded as 7-*p*-toluidino-3:6-dimethylphenoxazine,

It crystallises from ethyl alcohol or dilute acetone in brownish, orange-yellow needles or plates, m. p. 173°. The hydrochloride, $C_{21}H_{20}N_2 \cdot HCl$,

forms red rhombohedra, with a greenish, metallic reflex. The *platinichloride*, $2\text{C}_{21}\text{H}_{20}\text{ON}_2\cdot\text{H}_2\text{PtCl}_6$, has a yellowish-red colour. The *sulphate*, $\text{C}_{21}\text{H}_{20}\text{ON}_2\cdot\text{H}_2\text{SO}_4$, crystallises from alcohol in deep, red compact cubes. The *picrate*, $\text{C}_{27}\text{H}_{25}\text{O}_8\text{N}_5$, forms golden-yellow, microscopic needles, m. p. 227° . The base yields a phenylcarbimide derivative,

as colourless rosettes of needles, m. p. 188° (decomp.).

Attempts to acetylate, methylate, and form an oxims gave negative results. When reduced, the base yields *p*-toluidine. J. J. S.

Preparation of 5:5-Dialkylbarbituric Acids. ALFRED EINHORN (D.R.P. 225457).—The action of oxalyl chloride on dialkylmalonamides affords 78–80% of the theoretical yield of the respective dialkylbarbituric acid.

Equal weights are heated together on the water-bath during several hours, water is added, and the product collected. F. M. G. M.

Condensation Products of Alloxan. OTTO KÜHLING (*Ber.*, 1910, 43, 2406–2417. Compare *Abstr.*, 1905, i, 944; 1908, i, 571; Kühling and Schneider, *ibid.*, 1909, i, 424).—Alloxan condenses with ethyl benzoylacetate or the corresponding methyl ester in the presence of a mixture of water and alcohol, saturated at -6° to -8° , with hydrogen chloride, yielding carbethoxy- or carbomethoxy-phenacyldialuric acid. These compounds resemble the phenacyldialuric acids as regards their behaviour towards dilute acids or acetic anhydride, but are readily decomposed into their components when boiled with water, mixed with sodium carbonate solution at the ordinary temperature, or treated with the usual reagents for ketones. The acetyl derivatives, are more stable, and react with sodium carbonate solution, yielding compounds which are regarded as carbethoxy(methoxy)-phenacylbarbituric acids.

Carbethoxyphenacyldialuric acid,

crystallises from alcohol in rhombic prisms, m. p. $207\text{--}208^\circ$ (decomp.) after turning red at 180° . When boiled for several hours with 12% hydrochloric acid, it yields phenacyldialuric acid. The *acetyl* derivative,

crystallises in long plates, melts at $167\text{--}168^\circ$, then solidifies, and melts again at $235\text{--}236^\circ$. *Carbethoxy*

phenacylbarbituric acid, $\text{CO}_2\text{Et}\cdot\text{CHBz}\cdot\text{CH}\begin{matrix} \diagup \text{CO}\cdot\text{NH} \\ \diagdown \text{CO}\cdot\text{NH} \end{matrix} \text{CO}$, crystallises

from alcohol in prisms, m. p. $239\text{--}240^\circ$, and is also formed when the acetyl derivative is heated at $180\text{--}190^\circ$. It yields a *sodium salt*,

$\text{C}_{15}\text{H}_{13}\text{O}_6\text{N}_2\cdot\text{Na}$, in the form of prismatic needles, and reacts with benzenediazonium chloride solution, yielding alloxanphenylhydrazones.

With phenylhydrazine in acetic acid solution, the barbituric acid yields a yellow, amorphous precipitate, and yellowish-red crystals of a compound, $\text{C}_{21}\text{H}_{18}\text{ON}_4$, m. p. $174\text{--}175^\circ$, which is probably a *keto-*

Carbomethoxyphenacyldialuric acid,

forms colourless prisms, m. p. 221° (decomp.). The acetyl derivative, $\text{C}_{14}\text{H}_{14}\text{O}_8\text{N}_2$, also forms prisms, melts at 158° , resolidifies, and again melts at $241\text{--}242^\circ$. *Carbomethoxyphenacylbarbituric acid*, $\text{C}_{14}\text{H}_{12}\text{O}_8\text{N}_2$, forms colourless needles, m. p. $246\text{--}247^\circ$ (decomp.). J. J. S.

Compounds of Piperazine with Phenols. H. STÉVIGNON (*Bull. Soc. chim.*, 1910, [iv], 7, 922—926).—Schmidt and Wichmann have shown that piperazine forms additive compounds with phenol and with quinol (Abstr., 1892, 210), and the author has extended this observation to other phenols, and finds that 1 mol. of piperazine combines with 2 mols. of a monohydric phenol or with 1 mol. of a dihydric phenol. In all cases the two substances were allowed to react in alcohol.

The following substances were prepared: *Di-o-cresolpiperazine*, m. p. $51\text{--}52^\circ$ (approx.), pale yellow crystals. *Dicarvacrolpiperazine*, m. p. $85\text{--}86^\circ$ (approx.), colourless needles. *Dithymolpiperazine*, m. p. 88° , brilliant, colourless needles. *Di-β-naphtholpiperazine*, m. p. 110° (approx.), greyish-white crystals. *Catecholpiperazine*, bright brown needles. *Diquaiacolpiperazine*, m. p. 98° (approx.), brilliant colourless lamellae. The piperazine in these compounds behaves as a diacidic base, and can be titrated directly with *N*/10-sulphuric acid, using helianthin-4 as indicator. T. A. H.

Action of Sulphuric and Hydrochloric Acids on *endo*Bisazo-derivatives. I. HENRI DUVAL (*Bull. Soc. chim.*, 1910, [iv], 7, 915—922).—It is shown that under the action of sulphuric or hydrochloric acid, the *endo*bisazo-compounds behave like azodiazocompounds, one azo-group being replaced by a hydroxyl group, which in the case of hydrochloric acid is then replaced by chlorine, whilst the second remains intact. Instances of this reaction have been given already (Abstr., 1907, i, 663), and are now repeated with experimental details. The author suggests that the substances now called indazoles should be re-named *isonzindoles*, and that the present *iso*azindoles should be named *azindoles*.

When 4:4'-diacetylbisazodiphenylmethane [4:6'-diacetylphenylbenzisindazole] (Abstr., 1908, i, 706) is heated with a 53% solution of sulphuric acid at $100\text{--}105^\circ$, it is converted in the course of a few minutes into 2'-hydroxy-4:6'-diacetyl-3-phenylbenzisindazole,

which in the author's new nomenclature would be "2'-hydroxy-4:6'-diacetyl-3-phenylindazole." It melts at 235° , forms bright yellow needles from alcohol, and is soluble in dilute sodium hydroxide solution, but not in ammonia. T. A. H.

Quinoline and Indole Derivatives from *para*Diaminodiphenylmethane. WALTHER BORSCHKE and G. A. KIENITZ (*Ber.*, 1910, 43, 2333—2337).—6:6'-*Diquinolylmethane*, $\text{CH}_2(\text{C}_9\text{NH}_8)_2$, can be prepared from *p*-diaminodiphenylmethane by the usual Skraup synthesis. It

forms a limpid, brown oil, which solidifies slowly, and can be obtained as colourless needles, m. p. 160°.

4:4'-*Dihydrazinodiphenylmethane*, $\text{CH}_2(\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{NH}_2)_2$, prepared by diazotising β -diaminodiphenylmethane and reducing the diazo-compound by Fischer's method, crystallises from benzene in colourless plates, m. p. 71—72°, but turns brown in the course of a few hours when exposed to the air. The *hydrochloride* forms a white, crystalline powder, and is somewhat more stable. The *dibenzylidene* derivative, $\text{CH}_2(\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{N}:\text{CHPh})_2$, crystallises from glacial acetic acid in golden-yellow plates, m. p. 193—194°. The condensation product with dextrose, $\text{CH}_2(\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{N}:\text{CH}[\text{CH}\cdot\text{OH}]_4\cdot\text{CH}_2\cdot\text{OH})_2$, is a dark yellow, crystalline powder, m. p. 122—123° (decomp.).

The condensation product with *cyclohexanone* readily loses ammonia when warmed with glacial acetic acid (Abstr., 1908, i, 365), and yields *p-di- $\alpha\beta$ -tetramethyleneindolylmethane* (*bis*tetrahydrocarbazolylmethane, formula I.), which separates from dilute acetone in yellow crystals, m. p. 265°. From

cyclopentanone, *p-di- $\alpha\beta$ -trimethyleneindolylmethane* (formula II) is formed in a similar manner; it separates from dilute acetic acid in a yellow powder, m. p. 262°.

Suherone yields *p-dipentamethyleneindolylmethane*,

which does not melt at 300°.

J. J. S.

Synthesis of the Safranines. W. G. SAFOSHNIKOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 505—512. Compare Barbier and Sisley, Abstr., 1905, i, 840).—The author disagrees with the ordinarily accepted view of the formation of the safranines and indulines, namely, that the first products of the reaction are indamines which then condense with the amines. *p*-Benzoquinonedi-imide is quite inert towards amines, only reacting when one of the hydrogen atoms of the amino-group is displaced by a halogen, and this the more readily the greater the atomic weight of the halogen. It is, therefore, probable that the first product in the formation of the safranines is *p*-benzoquinonedi-chlorodi-imide (or a similar compound), which then reacts with the amines. The tertiary amines only form these condensation products when they have the property of readily losing one of their radicals. The secondary and primary amines are equally active, although some primary amines, such as tribromoaniline and dibromotoluidine, do not react at all or with difficulty. In all cases an excess of the amine is favourable to a good yield, and as the molecular weight of the amine increases, the number of molecules

of the amine that combine with one of the *p*-benzoquinonedichlorodi-imide decreases. Polyamines, particularly *m*-diamines, react readily with *p*-benzoquinonedichlorodi-imide. If in a mixed secondary and primary amine, a methyl group is introduced in an ortho-position to the primary amino-group, the compound so formed reacts very readily with *p*-benzoquinonedichlorodi-imide. Thus 4-phenyltolylene-2:4-diamine reacts readily with the quinone, forming the leuco-compound of indamine, which passes readily into indamine and then by loss of the

obtaining safranines is claimed to be far better than any method hitherto described.

heavier amino-group can be converted into the azone (annexed formula), which is the formula proposed for safranine. Its advantages over the formula hitherto accepted are discussed. Thus it readily explains why only one amino-group reacts when safranine is diazotised; also, why only a monoacetyl derivative is obtained and so forth. This method of Z. K.

Synthesis of the Simplest Safranin: 3:6 Diamino 5-phenazonium Chloride. W. G. SAPOSHNIKOFF and N. N. ORLOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 512—522. Compare preceding abstract).—3:6-Diamino-5-phenyl-2-methylphenazonium chloride was prepared by heating a mixture of *p*-benzoquinonedichlorodi-imide (1 mol.) and 4-phenyltolylene-2:4-diamine (2 mols.) in alcoholic solution on a water-bath for fifteen to twenty minutes. The yield is 86.7—93.2% of the theoretical. The substance forms bright yellow crystals soluble in concentrated sulphuric acid with an emerald-green colour, turning violet and red on dilution. The base is precipitated by alkali hydroxides, but not by alkali carbonates, and is readily soluble in water. The *nitrate* and *chromate*, $(C_{19}H_{17}N_4)_2Cr_2O_7$, were prepared.

The *dinecyl* derivative, $C_{24}H_{21}O_2N_4Cl$, crystallises from alcohol in yellowish-green, and from glacial acetic acid in brick-red, crystals, of which the chromate was prepared. By eliminating one amino-group by means of the diazo reaction, monomethylaposafranine (annexed formula) is obtained (compare Kehrman and Wetter, Abstr., 1898, i, 437). It forms a *chromate*, $(C_{19}H_{16}N_3)_2Cr_2O_7$.

By removing the amino-group from methylaposafranine, or both amino-groups from the original safranin, phenotoluophenazonium is formed. Diazosafranin condenses with β -naphthol to form a blue dye, of which the *chromate*, $(C_{29}H_{22}O_2N_3)_2Cr_2O_7$, was analysed. Z. K.

Synthesis of Safranin with a Naphthalene Nucleus (3:6-Diamino-5-phenyl-2-methylnaphthaphenazonium Chloride). N. N. ORLOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 522—530. Compare preceding abstract).—3:6-Diamino-5-phenyl-2-methylnaphthaphenazonium chloride, prepared from naphthaquinonedichlorodi-imide and 4-phenyltolylene-2:4-diamine, forms yellowish-green crystals; the *chromate*, $(C_{23}H_{19}N_4)_2Cr_2O_7$, is described. By eliminating one amino-

group, the *monoamino*-compound (annexed formula) is obtained, of which the *chromate*, $(C_{23}H_{18}N_3)_2Cr_2O_7$, was analysed. On removing the amino-group, the chromogen *5-phenyl-2-methylnaphthaphenazonium* isolate as the *ferrichloride*, $C_{23}H_{17}N_2Cl_4Fe$, m. p. 205° is obtained. The latter is converted, in ammoniacal solution, into the amino compound. The diazotised naphthasafranin gives a blue dye with β -naphthol, the *chromate*, $(C_{23}H_{24}ON_5)_2Cr_2O_7$, of which was analysed.

Furoxans. IV. Action of Amines on Dibenzoylfuroxan
 HEINRICH WIELAND and ERWIN GMEIN (*Annalen*, 1910, 375 297—307. Compare Abstr., 1901, i, 609, 610).—The authors' recent work (*loc. cit.*) has shown that the furoxan ring is very easily ruptured by ammonia or amines, amidoximes being produced, thus:

Under suitable conditions the amidoxime may experience ring closure, with the production of *isooxazole* derivatives. These results are utilised to show that Boeseken's benzoyl-*p*-bromoanilinfurazan (this vol., i, 643), obtained by warming diphenyldinitrosoacetyl (di-benzoylfuroxan) with ethereal *p*-bromoaniline, is not a furazan, but a nitrosoisooxazole derivative. Using ethereal aniline (2 mols.), the authors obtain, after the removal of the precipitated benzanilide and evaporation of the solvent, an orange-coloured syrup of the unstable anilino-oxime, $\text{OH} \cdot \text{N} : \text{C} \text{Bz} : \text{C} (\text{N} \cdot \text{OH}) \cdot \text{NHPh}$, which is converted by warm acetic acid into *4-nitroso-3-anilino-5-phenylisooxazole*,

this crystallises in brownish-red needles, and is reduced in alcoholic solution by zinc dust and acetic acid to *4-amino-3-anilino-5-phenylisooxazole*, m. p. 147° (decomp.). An acetic acid solution of the latter is converted by sodium nitrite at 0° into an unstable, red nitrosoamine, $\text{CPh} : \text{C} (\text{NH}_2) \text{---} \text{N} \text{---} \text{C} \cdot \text{NHPh} \cdot \text{NO}$, which rapidly changes to diphenyl-*3:4-gem-triazoloisooxazole* (*3:4-phenylazimino-5-phenylisooxazole*),

m. p. 151° (decomp.), which crystallises in yellow leaflets, gives a magenta coloration with phenol and sulphuric acid, and develops a dark green coloration with sulphuric acid alone.

When warmed with alcohol or acetic acid, the brownish-red nitrosoanilinophenylisooxazole is converted into the isomeric, colourless azoxime, *3-benzoyl-5-anilino-1:2:4-oxadiazole*, $\text{C} \text{Bz} : \text{N} \text{---} \text{N} \text{---} \text{C} \cdot \text{NHPh}$ (as stated by Boeseken), the formation of which is explained by the intermediate production of the furazan ring, $\text{C} (\text{NHPh}) : \text{N} \text{---} \text{N} \text{---} \text{C} \text{Bz}$.

which then undergoes a partial Beckmann transformation (Böeseken, *loc. cit.*)

[With ALEX. ROSEBU.]—Results similar to the preceding are obtained when dibenzoylfuroxan is decomposed by *p*-anisidine. Nitro-3-*p*-anisidino-5-phenylisooxazole, decomp. 123°, crystallises as glistening, black needles, forms dark red solutions, is converted by boiling alcohol mainly into the isomeric azoxime, and is reduced by lime and acetic acid to 4-amino-3-*p*-anisidino-5-phenylisooxazole, m. p. 51°. This base in acetic acid is converted by sodium nitrite into benzyl-*p*-anisyl-3:4-gem-triazoloisooxazole,

mp. 141°, which crystallises in golden-yellow leaflets.

Contrary to Böeseken's statement that dibenzoylfuroxan only reacts with primary amines, the authors find that a vigorous reaction occurs with ethereal piperidine.

C. S.

trazoles. XVII. Rearrangement of the Tautomeric Salts 1:4-Diphenyl-5-thionurazole and 1:4-Diphenyl-5-thiolzole. SIDNEY NIEDLINGER and SALOMON F. ACREE (*Amer. Chem.*, 1910, 44, 219—251).—The slow rearrangement of tautomeric salts and their final states of equilibrium have been investigated by the authors, but the tautomeric salts of such acids have not hitherto been studied. In view of the importance of such work as a test of the validity of Acree's theory, an investigation has now been made of the salts of 1:4-diphenyl-5-thionurazole and 1:4-diphenyl-5-thiolzole.

It has been shown by Busch and Holzmann (*Abstr.*, 1901, i, 234) that Murekwald's thiosemicarbazides (*Abstr.*, 1893, i, 46) are structural isomerides of the types $\text{NH}_2 \cdot \text{NR} \cdot \text{CS} \cdot \text{NHR}$ and $\text{NHR} \cdot \text{NH} \cdot \text{CS} \cdot \text{NHR}$.

The action of carbonyl chloride on $\beta\delta$ -diphenylthiosemicarbazide, a compound, m. p. 141°, is obtained, which was regarded by Busch and Holzmann (*loc. cit.*) as 5-thiol-1:4-diphenylurazole,

but (Abstr., 1902, i, 322) has stated that when this substance is heated, it undergoes transformation into a compound, m. p. 219—221°, which he assumed to be 5-thion-1:4-diphenylurazole, $\text{NPh} \begin{array}{l} \text{CS} \cdot \text{NPh} \\ \diagup \quad \diagdown \\ \text{CO} \cdot \text{NH} \end{array}$

or a mixture of the two forms in equilibrium, $\text{Ph} \begin{array}{l} \text{CS} \text{---} \text{NPh} \\ \diagup \quad \diagdown \\ \text{C}(\text{OH}) \cdot \text{N} \end{array}$.

It is now shown, however, that these views are incorrect, and that the compound of m. p. 141° is actually 5-thion-1:4-diphenylurazole, which is able of existing in two forms in equilibrium, whilst the compound of m. p. 219—221° is 5-thiol-1:4-diphenylurazole.

The action of diazomethane and diazoethane on 5-thion-1:4-diphenylurazole and 5-thiol-1:4-diphenylurazole, compounds are obtained which differ from those produced by the action of alkyl iodides

M. XCVIII

on the sodium salts of the urazoles. With diazomethane, 5-thion-1:4-diphenylurazole yields a *compound*, $C_{18}H_{12}ON_2S$, m. p. 74.5–75.5; and with diazoethane it furnishes an *ester*, $C_{18}H_{14}ON_2S$, m. p. 79–81°. By the action of diazomethane on 5-thiol-1:4-diphenylurazole, an *ester*, m. p. 129.5–130.5°, is produced, isomeric with that obtained from the thionurazole. The thiolurazole and diazoethane give an *ester*, m. p. 105.5–107.5°.

It has been found that 5-thion-1:4-diphenylurazole and 5-thiol-1:4-diphenylurazole yield sodium salts which are reconverted into the respective urazoles on addition of hydrochloric acid. Both salts react with methyl iodide, and the reaction takes place about eighty times as rapidly with the salt of the thiolurazole as with that of the thionurazole. The *methyl ester* of the thionurazole is obtained as a red, viscous oil, which gradually becomes semi-solid. The methyl ester of the thiol compound is identical with that obtained by the action of carbonyl chloride on $\beta\beta$ -diphenyl- γ -methylthiosemicarbazide.

The sodium salts have been esterified quantitatively, and a method has been devised for analysing mixtures of the salts or esters depending on the fact that, under certain conditions, the methyl ester of 5-thiol-1:4-diphenylurazole is completely hydrolysed by alkali hydroxide in presence of chloroform, whilst that of the thionurazole is but little affected by this treatment.

The sodium salts of the two urazoles are mutually convertible into one another by two apparently reversible unimolecular reactions, the velocity of rearrangement of sodium 5-thion-1:4-diphenylurazole being about nine times as great as that of sodium 5-thiol-1:4-diphenylurazole.

E. G.

5-Hydroxy-1:2:3-triazole. THEODOR CURTIUS and AUGUST BOSCHMÜHL (*Ber.*, 1910, 43, 2441–2446).—5-Hydroxy-1:2:3-triazole,

was prepared by Curtius and Thompson (*Abstr.*, 1907, i, 93) from diazoacetamide, and by Dimroth and Aickelin (*Abstr.*, 1907, i, 139) from ethyl-1-phenyl-5-triazolonecarboxylate. It has now been more closely studied (compare Dimroth, this vol., i, 518). 5-Hydroxy-1:2:3-triazole has m. p. 129°; it is a monobasic acid, and forms a colourless crystalline *potassium salt* and a *hydrazonium salt*, $C_3H_2N_3(ON)_2$, crystallising in needles, m. p. 117°. An ammonium salt could not be prepared; on evaporation to dryness with ammonia, a colourless crystalline substance was obtained of the same composition as hydroxy-1:2:3-triazole, m. p. about 95°. On the addition of bromine water to an aqueous solution of 5-hydroxy-1:2:3-triazole, it decomposes, the gas evolved consisting of molecular proportions of nitrogen and carbon monoxide. Probably dibromoglycolic acid (Curtius and Welde, *Abstr.*, 1907, i, 449) is first formed, and decomposes into oxalic acid, which yields carbon monoxide.

E. F. A.

Diazoacetyl-glycinehydrazide and 5-Hydroxy-1:2:3-triazole-1-acetylhydrazide. THEODOR CURTIUS and ERNST WELDE (*Ber.*, 1910, 43, 862–880).—Curtius and Thompson (*Abstr.*, 1906, i, 404, 240;

1907, i. 95) have shown that ethyl diazoacetylglucine yields derivatives of 5-triazolone-1-acetic acid when treated with ammonia or alkali, and the present authors find that hydrazine hydrate reacts similarly with the ester.

Diazoacetylglucinehydrazide, $\text{N}_2\cdot\text{CH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{NH}_2$, prepared by boiling hydrazine hydrate with ethyl diazoacetylglucine (for which an improved method of preparation is given) in alcoholic solution, crystallises in yellow, glistening leaflets, which darken at 120° and decompose at 147° ; the *benzylidene* derivative,

forms minute, almost colourless needles, m. p. $199-200^\circ$, and the *i-propylidene* derivative, $\text{N}_2\cdot\text{CH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{N}\cdot\text{CMe}_2$, crystallises in bright yellow, glistening leaflets, m. p. 178° (decomp.). When treated with hydrogen chloride in alcoholic solution, the diazo-hydrazide yields *chloroacetylglucinehydrazide hydrochloride*,

a colourless powder, m. p. 168° ; the *benzylidene* derivative of the base is a colourless powder, which does not melt at 300° .

When a cold aqueous solution of diazoacetylglucinehydrazide is treated with a trace of sulphuric acid, nitrogen is evolved, and the solution with benzaldehyde furnishes *hydroxyacetylglucinebenzylidenehydrazide*, $\text{OH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{N}\cdot\text{CHPh}$, crystallising in small, colourless needles, m. p. 143° .

Hydrazonium 5-hydroxy-1:2:3-triazole-1-acetylhydrazide,

is formed as a by-product in the preparation of diazoacetylglucinehydrazide, and is obtained in larger yield by heating ethyl diazoacetylglucine in more concentrated solution with a greater excess of hydrazine hydrate; it forms pale red, feathery crystals, m. p. 175° (decomp.). The *potassium* (m. p. 245° , decomp.) and *silver* (decomp. 209°) salts are described. The *hydrazonium* salt of 5-hydroxytriazole-1-acetic acid, $\text{C}_4\text{HN}_5(\text{ON}_2\text{H}_5)\cdot\text{CH}_2\cdot\text{CO}_2\cdot\text{N}_2\text{H}_5$ (reddish needles, m. p. 172°), was also prepared.

5-Hydroxy-1:2:3-triazole-1-acetylhydrazide, $\text{C}_4\text{H}_7\text{O}_2\text{N}_5\cdot\text{H}_2\text{O}$, prepared from the potassium or silver salt, crystallises in colourless, right-angled tablets, m. p. 147° , which are anisotropic; the *hydrochloride*, a colourless powder, m. p. 174° (decomp.), the *benzylidene* derivative,

m. p. 190° (decomp.), and the *isopropylidene* derivative, m. p. $155-160^\circ$, were prepared.

J. C. C.

Diazoacetylglucylglucinehydrazide. THEODOR CURTIUS and THOMAS CALLAN (*Ber.*, 1910, 43, 2447-2457).—Curtius and Welde (preceding abstract) have shown that ethyldiazoacetylglucine and hydrazine hydrate yield at first diazoacetylglucinehydrazide, which with a further amount of hydrazine hydrate undergoes rearrangement to the *hydrazonium* salt of 5-hydroxytriazole-1-acetylhydrazide. It is now shown that ethyldiazoacetylglucylglucine forms *diazoacetylglucylglucinehydrazide*. This has the properties of a true diazo compound and also of an acid hydrazide, liberates nitrogen with dilute mineral

acids, and forms a crystalline compound with benzaldehyde. When boiled in aqueous solution, *hydroxyacetylglcylglycinehydrazide*,

is formed. Prolonged boiling of the hydrazide with hydrazine hydrate converts it into a yellow oil, the *hydrazonium* salt of 5-hydroxytriazole-1-acetylglcylglycinehydrazide, the benzylidene derivative of which was obtained crystalline. The triazole derivative is more readily obtained on warming the hydrazide with dilute alcoholic potassium hydroxide, when the *potassium* salt is obtained as a colourless, very hygroscopic substance. The benzylidene derivative of the triazole, as also that of the 5-hydroxytriazole-1-acetylhydrazide of Curtius and Welde (*loc. cit.*), combines with *p*-toluenediazonium sulphate, forming red- and orange-hued azo-dyes respectively.

Diazoacetylglcylglycinehydrazide,

crystallises in lustrous, yellow needles, aggregated in rosettes, m. p. 167° (decomp.). *Diazoacetylglcylglycinebenzylidenehydrazide* is a yellow, amorphous powder, m. p. 180—181° (decomp.).

Hydroxyacetylglcylglycinehydrazide is a colourless, very soluble powder, which blackens at 230°, decomp. 240°. *Hydroxyacetylglcylglycinebenzylidenehydrazide* forms short, colourless plates, decomp. 240°.

Acetylhydroxyacetylglcylglycinehydrazide,

is a colourless, microcrystalline powder, decomp. 180°.

5-Hydroxytriazole-1-acetylglcylglycinehydrazide,

the *hydrazonium* salt is a colourless oil, soluble in water with a strongly alkaline reaction; the *potassium* salt is a colourless, crystalline mass.

5-Hydroxytriazole-1-acetylglcylglycinebenzylidenehydrazide is a pale brown, amorphous powder, m. p. 180° (decomp.). It condenses with *p*-toluenediazonium sulphate in dilute sodium hydroxide solution, forming 4-toluenazo-5-hydroxytriazole-1-acetylglcylglycinebenzylidenehydrazide, which crystallises in small, reddish-brown needles, m. p. 151.5°.

4-Toluenazo-5-hydroxytriazole-1-acetylbenzylidenehydrazide forms an orange powder, m. p. 149.5° (decomp.). E. F. A.

Transformation of Diazo-hydrazides into Monohalogen Hydrazides and Azoimides. THEODOR CURTIUS and THOMAS CALLAN (*Ber.*, 1910, 43, 2457—2467).—By the action of gaseous hydrogen chloride on diazoacetylglcylglycinehydrazide, Curtius and Welde (this vol., i, 786) obtained chloroacetylglcylglycinehydrazide hydrochloride. The action of hydrogen bromide and hydrogen iodide has now been studied in a similar manner. The iodine derivative could not be obtained pure, but it condenses with benzaldehyde to form *iodoacetylglcylglycinebenzylidenehydrazide*, $\text{CH}_2\text{I}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{N}\cdot\text{CHPh}$. Two other compounds are also formed together with the iodo-derivative, the one, formed in small quantity only, has a high melting point, and is probably the symmetrical secondary hydrazide of iodoacetylglcylglycine. The other, $\text{C}_6\text{H}_{12}\text{O}_2\text{N}_3\text{I}$, crystallises from alcohol in needles; when boiled

with water an ethyl group disappears, and it is supposed that the original compound contains an ethyl group in the hydrazine residue.

When treated with a concentrated aqueous solution of sodium nitrite, the halogen acetylglycinehydrazides are converted into halogen acetylglycineazoimides. These melt and decompose explosively at higher temperatures; they form anilides with aniline, and boiling with alcohol converts them into urethanes.

By the action of hydrogen chloride on diazoacetylglucylglycinehydrazide, a colourless powder, m. p. 172—174°, was obtained, which did not correspond in composition with chloroacetylglucylglycinehydrazide hydrochloride.

Chloroacetylglucineazoimide, $\text{CH}_2\text{Cl}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{N}_3$, crystallises from ether in well-formed, colourless, lustrous plates. The aqueous solution when heated desposits a colourless, insoluble powder, m. p. 184—185°.

Chloroacetylglucineanilide forms centimetre-long, colourless needles, m. p. 170—171°.

Chloroacetylaminomethylurethane, $\text{CH}_2\text{Cl}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CO}_2\text{Et}$, crystallises in beautiful plates of silky lustre, m. p. 149—150°.

Bromoacetylglucinehydrazide hydrobromide, prepared by the action of hydrogen bromide on diazoacetylglucinehydrazide in alcoholic solution, is a heavy, crystalline powder, deliquescent in the air, decomp. 113°.

Bromoacetylglucinebenzylidenehydrazide is a colourless, amorphous powder, m. p. 187—190° (decomp.).

Bromoacetylglucineazoimide crystallises from ether in colourless, silky, lustrous plates. It melts and explodes when heated on a spatula.

Bromoacetylglucineanilide crystallises in bunches of intergrown, small needles, m. p. 161—162°.

Bromoacetylaminomethylurethane separates from alcohol in colourless plates, m. p. 154—155°.

Iodoacetylglucinebenzylidenehydrazide was obtained as an almost colourless, amorphous powder, m. p. 177—179°.

Iodoacetylglucineazoimide forms colourless platelets, which melt and explode.

Iodoacetylaminomethylurethane crystallises in well-formed, colourless plates, m. p. 171° (decomp.).

Iodoacetylglucine-ethylhydrazide (?) was obtained in colourless, microscopic needles, m. p. 147—148°. When boiled with water a residue, m. p. 102—104° (decomp.), remained, which with benzaldehyde formed the above-described iodoacetylglucinebenzylidenehydrazide.

Iodoacetylglucineamide, $\text{CH}_2\text{I}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}_2$, prepared by the action of hydrogen iodide on diazoacetylglucineamide, crystallises in glistening, colourless needles and plates, m. p. 173—175°.

E. F. A.

Hydrazidicarboxylhydrazide. ROBERT STOLLÉ [and, in part, O. H. LEVERKUS and R. KRAUCH] (*Ber.*, 1910, 43, 2468—2470 compare Curtius and Heidenreich, *Abstr.*, 1895, i, 12; 1896, i, 143). On prolonged boiling of ethyl hydrazidicarboxylate with hydrazine

hydrate in alcoholic solution, the hydrazine salt of hydrazidicarboxylamide separates out. The mother liquors, when shaken with benzaldehyde, yield *dibenzylidenhydrazidicarboxylhydrazide*,

crystallising + H_2O in slender plates, m. p. 229° .

Hydrazidicarboxylhydrazide hydrochloride, prepared from the benzylidene compound by heating with hot hydrochloric acid, crystallises in small, glistening prisms, decomp. 203° . The condensation product with anisaldehyde has m. p. 218° , that with salicylaldehyde has m. p. 238° . On heating ethylhydrazidicarboxylate with hydrazine hydrate at 76° and evaporating to dryness in a vacuum, *hydrazidicarboxylhydrazide*, $\text{NH}_2\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}\cdot\text{NH}_2$, is obtained in monoclinic prisms, m. p. 196° . It reduces ammoniacal silver nitrate in the cold, and Fehling's solution when warmed. The sulphate (+ H_2O) crystallises in strongly refractive prisms, m. p. 210° (decomp.).

Hydrazidicarboxylazoinide has m. p. 146° , and detonates very violently. With aniline in ethereal solution it forms *hydrazidicarboxylanilide*.

Hydrazidicarboxylethylamide crystallises in plates, m. p. 255° .

Hydrazidicarboxylphenylhydrazide has m. p. 213° (decomp.).

E. F. A.

Stereomeric Azobenzenes. CATHERINE V. GORTNER and ROSS AIKEN GORTNER (*J. Amer. Chem. Soc.*, 1910, 32, 1294—1296).—Although it is evident from the structural formula of azobenzene that it should be capable of existence in *syn*- and *anti*-modifications, only one form has hitherto been described.

On heating azoxybenzene with iron filings, a distillate was obtained which consisted of a red liquid containing a crystalline substance. On removing the red liquid by means of light petroleum, in which it is readily soluble, a substance, m. p. 237° (corr.), was left in the form of light grey needles, representing about 1% of the azoxybenzene used. This substance was not further investigated.

The deep red solution was washed with cold dilute hydrochloric acid and afterwards with water, and was filtered and left to evaporate. In several cases, only ordinary azobenzene, m. p. 68° , crystallising in prisms, was obtained, but, in other cases, a deep red liquid was left, which furnished a stereoisomeride, m. p. 25° (corr.), crystallising in stellate groups of needles. From a mixture of the two isomerides, that melting at 68° may be removed by crystallisation, the new form being left in the mother liquor. The latter modification is probably *syn*-azobenzene. It has been converted into the form melting at 68° , but the reverse change has not been effected.

E. G.

Chromoisomerism and Homochromoisomerism of Azophenols. ARTHUR HANTZSCH (*Ber.*, 1910, 43, 2512—2516).—Anhydrous α -azophenol is green; β -azophenol is dark red (Willstätter and Benz, *Abstr.*, 1907, i, 566). These chromoisomerides, m. p. 216 — 218° (decomp., corr.), are very similar in physical and chemical properties, like the chromoisomeric nitroanilines (this vol. i, 475). The chromoisomeric α - and β -azophenols each form chrome-

isomeric (yellow, red, and green) alkali salts, which, however, show the same absorption spectra in solution. Also, α - and β -azophenols themselves in solution exhibit the same molecular extinction and the same absorption spectra (the orange tinge of β -azophenol in ether, described by Willstätter, is due to the presence of a little phenylhydrazine). Consequently, the azophenols, and also their salts, form homochromoisomerides in solution. This behaviour, examples of which have hitherto been furnished only by stereoisomerides, is further evidence of the *syn*- and *anti*-configurations of the α - and β -azophenols suggested by Willstätter.

C. S.

The Nitration of Diazonium Compounds. FARBERGER VORM, MEISTER, LUCIUS, & BRÜNING (D.R.-P. 224387).—The nitration of diazonium salts frequently yields nitrophenolic compounds, but if the diazotisation is effected in somewhat concentrated sulphuric acid and the solution (or suspension) subsequently treated with nitric acid, or a nitrating mixture, the corresponding nitrated diazonium salts are produced. α -Naphthylamine-5-sulphonic acid (23 parts) was dissolved in concentrated sulphuric acid (200 parts) and treated with nitrosyl-sulphuric acid (13 parts), dissolved in 50 parts of concentrated sulphuric acid, the mixture stirred, and the temperature maintained at 10 – 20° during several hours; it was then treated with potassium nitrate (11 parts), when the partly separated diazonium compound redissolved, and, on careful dilution, the nitrated product slowly separated in orange-yellow crystals.

F. M. G. M.

The Changes Produced by Urea in the Internal Friction and Electrical Conductivity of Protein Solutions. G. MORUZZI (*Biochem. Zeitsch.*, 1910, 23, 97–105).—The addition of urea to a protein solution in small concentration at first produces a decrease of conductivity, for as a non electrolyte, it lessens the movements of ions. Later, or in the case of greater concentrations within a few minutes, conductivity, rises owing to the formation of ammonia. Ammonia can also be detected by Nessler's reagent. Ammonium cyanate acts in the same way. Protein acts in this way in virtue of its being a pseudo-base. Urea is believed to owe its hæmolytic power, and its capacity to unite with complement, to the liberation of ammonia in fluids which contain protein.

W. D. H.

Action of Alkalis on Protein. III. ALBRECHT KOSSEL and FR. WEISS (*Zeitsch. physiol. Chem.*, 1910, 63, 165–169. Compare Abstr., 1909, i, 542).—Gelatin was digested with 0.5*N*-sodium hydroxide solution for seven to nineteen days, then precipitated with tannic acid containing a little sodium chloride (precipitate 1), and the filtrate saturated with sodium chloride (precipitate 2). To remove the sodium chloride from the filtrate, this was precipitated with phosphotungstic acid, the resulting precipitate decomposed with barium hydroxide, and the peptone derivatives precipitated by Kossel's silver nitrate-barium hydroxide method (precipitate 3), and, after removal of silver nitrate, the filtrate was precipitated with phosphotungstic acid, the latter removed, and the filtrate precipitated

with sodium bismuth iodide solution (precipitate 4). The precipitates were removed from each of the four precipitates by making use of acetone solutions, and then the precipitates were hydrolysed with 33 per cent. sulphuric acid. The precipitates before hydrolysis gave glycine, *dl*-ornithine, and *L*-valine. After acid hydrolysis, *dl*-histidine, *dl*-arginine, *D*-lysine, and proline were isolated. The action of alkalis on gelatin is thus similar to its action on clupein. Certain groups of the protein molecule are sensitive to racemisation so long as they are not united as "intraprotein." When the gelatin which has been partly racemised by alkali is subjected to acid hydrolysis, certain groups are racemised and others remain in the active form. The ornithine group especially appears to be readily racemised.

J. J. S.

The Amino-acids Obtainable by the Total Hydrolysis of Proteins. EMIL ABDERHALDEN (*Zeitsch. physiol. Chem.*, 1910, 63, 477—486).—A general account of the methods adopted and results obtained by the author and others is given. The paper also contains some new details of analytical results, and replies to criticisms.

W. D. H.

The Behaviour of Commercial Egg-albumin to Hydriodic Acid. THEODOR WEYL (*Zeitsch. physiol. Chem.*, 1910, 63, 236—242).—The name *iodalbose* is given to the product obtained by the action of hydriodic acid on egg-albumin; the iodine is firmly held, and the passage of ammonia through an alcoholic solution of *iodalbose* still leaves an iodine containing residuo which differs from *iodalbose* mainly in containing less carbon; it is termed *apoiodalbose*. By treatment with zinc, an iodine-free substance, *radalbose*, is obtained, which resembles the original egg-albumin closely in composition. Elementary analyses are given throughout.

W. D. H.

The Union of Iodine in Iodothyreoglobulin. ADOLF OSWALD (*Arch. exp. Path. Pharm.*, 1910, 63, 263—269. Compare Abstr., 1909, i, 123).—All hydrolytic agencies (boiling with acids or alkalis, action of the enzymes trypsin, erepsin, autolase) split off iodine from iodothyreoglobulin in an ionised condition as soon as the protein molecule is broken up into its final cleavage products. A part of the molecule is easily decomposed in this way, and readily yields up its iodine; another part is more resistant.

W. D. H.

Hordein and Bynin. A Contribution to our Knowledge of the Alcoholic Extracts of Barley and Malt Albumin. WILHELM KRAFT (*Zeitsch. ges. Brauwesen*, 1910, 33, 193—195. Compare Abstr., 1907, i, 666; 1908, i, 69).—An account of experiments on the extraction and reactions of hordein and bynin as obtained from malt and barley meal.

Methods of analysis, by hydrolysis and estimation of the decomposition products, are described, and the results compared with those obtained by Osborne and other workers; the two substances were found to resemble each other very closely, but the great difficulty of obtaining them pure rendered the interpretation of results very difficult.

F. M. G. M.

Thrombin, Antithrombin, and Prothrombin. WILLIAM H. HOWELL (*Amer. J. Physiol.*, 1910, 23, 453—473).—Thrombin was prepared by extracting washed fibrin with 8% sodium chloride solution, and then precipitating coagulable protein with chloroform. It is soluble in water, is not coagulated by boiling in neutral solutions, it gives the majority of the protein colour tests, and contains no phosphorus or sulphur. When allowed to remain in solution, especially at a high temperature, it gradually loses its power of coagulating fibrinogen. If putrefaction occurs, its coagulating power is at first increased and then lost. Saline solutions may be boiled without losing completely their coagulating power; dialysed solutions are more rapidly and completely destroyed by high temperatures. It keeps indefinitely when dried. Increasing amounts of thrombin give increasing amounts of fibrin, although in decreasing proportion. The weight of fibrin produced by a given submaximal amount of thrombin is not affected by the time during which the thrombin is allowed to act.

The conclusion drawn is that thrombin is probably not an enzyme. One part of thrombin can convert at least two hundred and fifteen times its weight of fibrinogen into fibrin. In the non-coagulable "peptone plasma" of the dog, it is antithrombin which prevents the action of thrombin. This anti-substance is destroyed at 75—80°, but not at 60°. Dilution with water causes spontaneous coagulation in "peptone plasma"; dilution with normal saline solution has no such effect. Prothrombin can be converted into thrombin in solutions free from calcium salts. One experiment is recorded of intravenous injection of large quantities of thrombin; no result followed.

W. D. H.

New Method for the Preparation of Crystals of Blood Colouring Matter. J. OFFRINGA (*Biochem. Zeitsch.*, 1910, 28, 106—111).—Methods previously employed for the preparation of pure hæmoglobin involve the action of heat, solvents, etc., on the blood. The author believes that these processes are not without influence on the labile hæmoglobin, and in any case crystal formation is very slow. He therefore mixes the corpuscles with kieselguhr, and submits the mass to hydraulic pressure. A fairly concentrated hæmoglobin solution is thus obtained, which, in the case of horse-blood, is frozen solid and centrifuged until again fluid, when a fair crop of crystals is left. The solution from pig's blood required previous concentration in an air current. The purity of the crystals was established by measurement of the extinction coefficients with the spectrophotometer. In each case the ratio 1:59 was obtained, agreeing closely with the Hüfner figure, 1:578, for oxyhæmoglobin.

The Refractive Indices of Solutions of Certain Proteins. II. The Paranucléins. T. BRAILSFORD ROBERTSON (*J. Biol. Chem.*, 1910, 8, 287—296. Compare this vol., i, 526).—The collective term paranucléin is applied to an insoluble substance which results from the incomplete peptic hydrolysis of casein, and also to the substance which is formed by high concentrations of pep-in from the synthetic products of complete casein hydrolysis. Additional confirmation of

the view that the substances are identical is obtained by a study of their refractive indices (this vol., i, 526), the value of α being 0.0014.

W. D. H.

Comparative Investigation on the Composition and Cleavage Products of Different Silks. X. Monoamino-acids of the Cocoon of the Italian Silk-worm. GEORG ROOSE. XI. The Monoamino-acids of the Cocoon of the Japanese Silk "Haruko." AKIKAZU SUWA (*Zeitsch. physiol. Chem.*, 1910, 68, 273—274, 275—276).—The following table gives the results in percentages with the two kinds of cocoon (freed from "gum") employed, calculated on the ash-free substance.

| | Italian. | Japanese. |
|---------------------|----------|-----------|
| Glycine..... | 33.5 | 35.0 |
| Alanine..... | 20.0 | 22.6 |
| Leucine..... | 0.75 | 0.7 |
| Serine | 1.9 | 0.7 |
| Aspartic acid | 1.0 | 1.0 |
| Glutamic acid | 0.25 | 0.07 |
| Phenylalanine..... | 1.2 | 1.3 |
| Tyrosine ... | 9.0 | 9.7 |
| Proline | 0.8 | 0.7 |

W. D. H.

Partial Hydrolysis of Proteins. II. Fibrin heteroproteose. PRÆBUS A. LEVENE, DONALD D. VAN SLYKE, and F. J. BIRCHARD (*J. Biol. Chem.*, 1910, 8, 269—284).—Heteroproteose was prepared from fibrin by a combination of Kühn's and Pick's methods; it contained C 49.52%; H 6.64%, and N 16.46%, which figures agree very well with Pick's. The results of hydrolysis in parts % are as follows:

| | | | |
|--------------------------|------|---------------------|-------|
| Glutamic acid | 9.51 | Aspartic acid | 4.73 |
| Leucine | 3.05 | Glycine | 0.15 |
| isoLeucine | 2.96 | Tyrosine | 3.43 |
| Valine | 3.54 | Arginine | 6.35 |
| Alanine | 3.39 | Histidine | 1.76 |
| Valine-alanine mixture.. | 1.36 | Lysine..... | 4.80 |
| Proline | 4.27 | Cystine | 4.10 |
| Phenylalanine ... | 2.45 | Ammonia | 1.65 |
| | | Total | 53.05 |

W. D. H.

The Study of Enzymes by means of the Synthetical Polypeptides. ARTHUR H. KOELKER (*J. Biol. Chem.*, 1910, 8, 145—175).—*r*-Alanylglycine can be used with great accuracy for the study of proteolytic enzymes, using the optical method. Solutions of *d*-alanylglycine and of *r*-alanylglycine remain unchanged in solution at 15—20° for thirteen months if toluene is used as a preservative. Buchner's grinding method yields the most active enzymes; precipitation with alcohol cannot be used with advantage in the purification of the active principle. The active principle of yeast which hydrolyses alanylglycine dialyses through parchment. The

solution of the enzyme, freed from most of the solids by dialysis, can be evaporated to dryness and redissolved without impairing its activity. The enzyme is still present after thirteen days' digestion at 37° ; heating to 75° for a few minutes destroys it completely. Sodium chloride has no influence on the rate of hydrolysis; calcium chloride in concentration 0.1% increases, and in concentration 1% inhibits, the hydrolysis.

W. D. H.

Isoelectric Constant of Pepsin. LEONOR MICHAELIS and HEINRICH DAVIDSOHN (*Biochem. Zeitsch.*, 1910, 28, 1-6).—From electrometric measurements of the changes in the hydrogen-ion concentration which are brought about by the passage of a current through solutions of pepsin containing hydrogen ions in gradually diminishing quantities, the authors have obtained the so-called isoelectric constant of pepsin. This is the hydrogen-ion concentration for which the positive and negative ions of the amphoteric electrolyte are equal, and the sum of the ions has a minimum value. The value found is 5.5×10^{-2} . For hydrogen-ion concentrations greater than this, the pepsin migrates to the cathode, and for smaller concentrations towards the anode. If the acidity is much greater than that corresponding with the isoelectric constant, the same effect is found as in the neighbourhood of the isoelectric point. This is attributed in the case of hydrochloric acid solutions to the formation of undissociated pepsinium chloride in presence of the excess of acid.

H. M. D.

Action of Pepsin and Hydrochloric Acid. EMIL ARDERHALDEN and EUGEN STEINBECK (*Zeitsch. physiol. Chem.*, 1910, 68, 293-311).—Gastric juice and hydrochloric acid of the same strength were allowed to act on peptone from various sources, and the result estimated polarimetrically; no change was produced in times varying from one to 170 hours. In similar experiments on native proteins after treatment with gastric juice or hydrochloric acid alone of the same concentration, no effect was observed in either case by the optical method. When solid, denaturalised protein was employed; hydrochloric acid alone produced little or no effect, but gastric juice caused a rise in rotation. If the solidified protein is placed for a short time in gastric juice, washed, and then placed in distilled water, the water after a time at 37° showed evidence of the presence of peptone by the biuret reaction and the polarimeter.

W. D. H.

The Action of Sodium Fluoride on Pepsin and Trypsin. ALBERT J. J. VANDEVELDE and EDM. POPPE (*Biochem. Zeitsch.*, 1910, 28, 134-137).—Amberg and Loevenhart showed that fluorides retard the action of lipase (*Abstr.*, 1908, i, 235), but in the concentrations used they have no effect on the digestive activity of pepsin and trypsin.

W. D. H.

Leucoprotease and Anti-leucoprotease. C. H. BURTON BRADLEY (*J. Hygiene*, 1910, 10, 209-230).—Lympho-protease is a pepsin-like enzyme associated with mono-nuclear leucocytes. Leucoprotease is a trypsin-like enzyme associated with polynuclear leuco-

cytes, and was in the present experiments obtained from pus cells. Experiments on its rate of action are given. It acts only in neutral or faintly alkaline media. The anti-tryptic action of serum varies in different animals, and in the same animal under different conditions (disease, etc.). In the present experiments, the variation in mammals was slight, and immunisation with leucoprotease caused only a small increase of anti-tryptic activity. Goats were the animals used.

W. D. H.

* The Erepsin of the Cabbage (*Brassica oleracea*). ALICE F. BLOOD (*J. Biol. Chem.*, 1910, 8, 215—226).—An active solution of a vegetable erepsin can be prepared from the cabbage by the ammonium sulphate method; the solution deteriorates very slowly if kept cool. It splits off tryptophan from Witte's peptone and from casein, and tyrosine from "peptone Roche." It clots milk and liquefies gelatin. It does not digest fibrin, egg white, or edestin in neutral, acid, or alkaline media, or in the presence of hydrocyanic acid. It is active over a considerable range of acidity and alkalinity, but is inhibited by a concentration of hydrogen ions corresponding with the acidity of methyl orange.

W. D. H.

Some Peculiarities of the Proteolytic Activity of Papain. LAFAYETTE B. MENDEL and ALICE F. BLOOD (*J. Biol. Chem.*, 1910, 8, 177—214).—The digestion of Witte's peptone by papain in the presence of the common antiseptics, judged by the tryptophan test, is very slow. Hydrocyanic acid, however, as Vines pointed out, accelerates proteolysis. The same accelerating effect is noticed when other proteins are digested by papain; it also accelerates the clotting of milk and liquefaction of gelatin. Whether there is more than one enzyme in papain is discussed. Hydrogen sulphide also accelerates the digestion. Hydrocyanic acid is provisionally placed with the co-enzymes. Another peculiarity of papain digestion is that digestion proceeds rapidly even after mixtures of the protein and enzyme have been boiled, and plant proteins are rapidly digested at 80°. Spontaneous deterioration occurs rapidly in solutions of papain; egg-white protects papain in some measure. Extracts of *Ascaris*, which are strongly antipeptic and anti-tryptic, exert no inhibition over papain proteolysis.

W. D. H.

Chemical Composition and Formation of Enzymes. II. HANS EULER and BETH AF UGGLAS (*Arkiv. Kem. Min. Geol.*, 1910, 3, No. 34, 1—12. Compare this vol., i, 345).—I. *Variation of Enzyme Content of Brewer's Yeast*.—No difference was found in the amount of invertase extracted from yeast dried (1) by treatment with absolute alcohol, (2) by treatment with 95% alcohol, (3) by drying in a vacuum at 40°, and (4) dried at 40° and subsequently slowly heated up to 80°. Yeast cultivated for several generations on dextrose-peptone contained about half as much invertase as the same yeast cultivated in sucrose-peptone. A yeast kept some days under toluene water and subsequently dried, had a low inverting power; the same yeast kept in yeast water and 0.5% sucrose, and strongly aerated, had a normal inverting power.

The diastatic power of barley corns germinated in the one case on moist sand, and in the other on sand moistened with $N/10$ -disodium phosphate solution, was in the ratio 1:2:3. The increase is attributed to the formation of a co-enzyme from the absorbed phosphate.

II. *Adsorption of Nitrogenous Substances*.—Iron and aluminium hydroxides adsorb proteins, but are not suited for the separation of protein and peptone. Charcoal entirely adsorbs peptone from solution, whilst from yeast extract it adsorbs both nitrogenous and nitrogen-free compounds. From erythrodextrin solutions about 90% is adsorbed by charcoal. Pectic acid is hardly adsorbed by kaolin, strongly by charcoal. Kaolin adsorbs the carbohydrates from yeast-extract preferentially to the nitrogen compounds. The peptones may be removed by charcoal, but the larger part of the nitrogenous constituents still remains.

E. F. A.

Inversion of Sucrose by Invertase. V. Destruction of Invertase by Acids, Alkalis, and Hot Water. C. S. HUDSON and H. S. PAINE (*J. Amer. Chem. Soc.*, 1910, 32, 985—989).—It has been shown in an earlier paper (this vol., i, 601) that invertase is destroyed by both acids and alkalis at 30° ; in each case, the destruction begins at a concentration of about $0.01N$, and becomes almost instantaneous at about $0.05N$. It is now found that as the temperature is raised, the rate of destruction by acids and alkalis increases, and that at about 60° water itself slowly destroys the enzyme, and at 65° the destruction is quite rapid. The destruction of invertase by hot water is evidently due to the same cause as its destruction by acids and alkalis, namely, the hydrolysis of the complex enzyme molecule. The rates of destruction in the same medium at different temperatures are compared, and the coefficients of the rates of increase for 10° rise of temperature are recorded. The average value of this coefficient is 3.1, which agrees with the general observation that this factor for most chemical reactions is between 2 and 4. The hydrolytic destruction of invertase by acids, alkalis, and hot water thus accords with the common types of chemical reactions.

It is shown that levulose has a remarkable power of protecting invertase from destruction. The rate of destruction by $0.04N$ -hydrochloric acid, $0.03N$ -sodium hydroxide, 50% alcohol, and hot water was first determined in the absence of the sugar and then with it present in concentrations of 2.7, 5.4, and 10.9%. The results are tabulated and plotted as a curve. This protective action of levulose can be best explained by assuming that the enzyme forms a compound with the sugar which is more resistant to the action of acids, alkalis, hot water, and alcohol than is invertase itself.

E. G.

Inversion of Sucrose by Invertase. VI. Theory of the Influence of Acids and Alkalis on the Activity of Invertase. C. S. HUDSON (*J. Amer. Chem. Soc.*, 1910, 32, 1220—1232).—It has been shown in earlier papers (this vol., i, 601; preceding abstract) that invertase is inactive in alkaline solutions, whilst in presence of dilute acids the activity rises to a maximum and afterwards decreases

with increasing acidity. These phenomena are most readily explained on the assumption that acids and alkalis combine with invertase in accordance with the law of mass-action, and thus prevent it from effecting the inversion of sucrose. On this hypothesis, a formula has been deduced by means of which the activity of invertase has been calculated over a considerable range of acidity and alkalinity. The results thus obtained agree closely with the observed activities.

E. G.

Inversion of Sucrose by Invertase. VII. Effect of Alcohol on Invertase. C. S. HUDSON and H. S. PAINE (*J. Amer. Chem. Soc.*, 1910, 32, 1350—1357).—The work described in this paper was carried out with the object of ascertaining the influence of alcohol of various concentrations on invertase at 30°. The observation of O'Sullivan and Tompson (*Trans.*, 1890, 77, 927), that the activity of invertase is reduced by alcohol, is confirmed, and it is found that the relation between the strength of the alcohol and the activity of the enzyme may be represented as a logarithmic or hyperbolic function.

Invertase is destroyed by alcohol of certain strengths. The destruction follows the course of unimolecular reactions; it is not appreciable if the alcohol is under 20%, is almost instantaneous at 50%, and then decreases to nearly zero at 80%. The rate of destruction is greatly retarded by the presence of sucrose, 6% of the sugar reducing the rate in 50% alcohol to about 1% of its original value. An equation is given expressing the rate of inversion of sucrose by invertase in presence of sufficient alcohol to effect the slow destruction of the enzyme, and is found to yield results agreeing closely with those obtained by experiment. In this way the activity of invertase has been determined in 50% and 60% alcohol.

Invertase can be precipitated by alcohol of about 90% strength without much being destroyed, and a preparation has been thus obtained with 78% of the activity of the original solution. In presence of sucrose very little invertase is destroyed, even when precipitated with 70% alcohol; by this method the enzyme has been recovered with 94—96% of the original activity.

E. G.

The Invertase of Malt Extracts. ALBERT J. J. VANDEVELDE (*Biochem. Zeitsch.*, 1910, 28, 131—133).—The extract of green malt inverts sucrose. Illustrative experiments are given. W. D. H.

Existence of a Specific Methylglucase in Beer Yeast. BRESSON (*Compt. rend.*, 1910, 151, 485—487. Compare Bierry, *Abstr.*, 1909, ii, 747).—Top-fermentation yeast hydrolyses α -methylglucose, whilst bottom-fermentation yeast does not. The author considers that an extract of the former contains a specific diastase not identical with invertin or maltase.

W. O. W.

Preparation of the Polypeptolytic Ferment of Yeast. A. H. KOELKER (*Zeitsch. physiol. Chem.*, 1910, 67, 297—303).—Whilst the filtered liquid obtained from yeast after treatment with chloro-

form very rapidly causes the hydrolysis of sucrose, it was found that alanylglycine is very slowly hydrolysed by the liquid, which is distinctly acid. When, however, calcium carbonate is added, much carbon dioxide is given off, and the liquid becomes very active, far more so than freshly-prepared expressed yeast.

The liquid is prepared by intimately mixing yeast (500 grams) and precipitated calcium carbonate (30 grams) and adding chloroform (50 c.c.). The yeast liquefies in one to three hours, and is then left for three to four days at the ordinary temperature and filtered. After treating with toluene, it is kept at 38° for auto-digestion until the rotatory power becomes constant (ten to forty hours). When filtered it is ready for use.

Calcium chloride does not increase the hydrolytic activity.

N. H. J. M.

Amylase (Diastase). ALFRED WOHL and E. GLIMM (*Biochem. Zeitsch.*, 1910, 27, 349—375).—The results of experiments on the effect of maltose and other sugars in checking the production of sugar from starch by amylase showed that the union of sugar with the enzyme increases with the concentration of the solution, and is sufficiently complete in 15% maltose solutions to render the production of sugar inappreciable. Similar results were obtained with 10% dextrose solutions, whilst 15% dextrin solution only reduced the activity of amylase to 25%. Galactose (20%) reduced the action by only one-third, and mannose (10%) by only 15%, whilst sucrose and laevulose had no effect.

Addition of 10% of maltose to solutions of amylase enables the latter to retain its enzymatic power when heated at 60° for ten minutes. The same effect is obtained by addition of 20% of dextrose, invert-sugar, and dextrin, whilst sucrose and starch have less effect. In each case the protective action depends on the concentration, and not on the absolute amount of the substance added.

N. H. J. M.

Amylases. II. Action of Pancreatic Amylase. E. C. KENDALL and HENRY C. SHERMAN (*J. Amer. Chem. Soc.*, 1910, 32, 1087—1105. Compare this vol., ii, 1011).—A study of the effect of electrolytes and of the concentration of starch on the amylolytic activity of pancreatin. The best commercial preparations are without action on pure starch, but are activated by the addition of neutral electrolytes, or, better, by the action of both a salt and alkali. Below the concentration for maximum activation, the optimum concentrations of salt and alkali depend on each other; above this concentration the optimum for the alkali depends chiefly on the concentration of the starch. Under these conditions, the initial rate of hydrolysis is independent of the amount of starch, but the rate diminishes as the reaction proceeds, the less rapidly the greater the amount of starch present. Equilibrium is attained in 1% starch solutions when the weight of maltose is about 85% of the initial weight of starch. Between 20° and 40°, the temperature-coefficient for amylase conforms to van't Hoff's rule for normal chemical reactions.

Apart from its action as an alkali, asparagine has little effect as an activating agent.
W. O. W.

Individuality of Cellase and Emulsin. GABRIEL BERTRAND and A. COMPTON (*Compt. rend.*, 1910, 151, 402—404. Compare this vol., i, 212, 220).—Previous experiments not having definitely established the non-identity of cellase and emulsin, a number of comparative observations have been made on the diastases extracted from almonds, maize, and bran. In each case the material was allowed to act on cellose and on amygdalin, when it was found that the ratio between the rates at which these substances underwent hydrolysis varied very considerably according to the source of the enzymes. It would appear, therefore, that cellase and emulsin are two specific enzymes occurring together in plants in variable proportions.
W. O. W.

δ -Emulsin. LEOPOLD ROSENTHALER (*Biochem. Zeitsch.*, 1910, 28, 408—412. Compare this vol., i, 403).—The action of emulsin on amygdalin occurs in three stages: in the first, mandelonitrile-glucoside and α -dextrose are formed; in the second, the first-named substance yields mandelonitrile (*d*-benzaldehyde cyanohydrin) and β -dextrose; in the third stage, the first-named substance splits up into benzaldehyde and hydrogen cyanide. The first two stages are hydrolytic, the third is not, and the enzyme responsible for the splitting of the nitrile (oxynitrilase) is distinct from that concerned in hydrolysis (glucosidase). Complete saturation with magnesium sulphate and filtration leads to the appearance in the filtrate of the hydrolytic enzyme only. In precipitation with copper sulphate and half saturation with ammonium sulphate, the filtrate contains both enzymes. The action of oxynitrilase is reversible.
W. D. H.

Lipase Reactions. HAROLD C. BRADLEY (*J. Biol. Chem.*, 1910, 8, 251—264).—When water is present in excess, the hydrolysis of triolein is regularly increased by an increase of lipase; this suggests a mass effect of lipase on the equilibrium of the reaction. A given amount of lipase can under optimum conditions liberate a definite amount of fatty acid from triolein irrespective of the mass of the latter. If more than 50% of water is present, reversion is negligible. Reversion is only appreciable in conditions approaching desiccation. It is possible that lipase, while important in the hydrolysis and absorption of fats, is not important as a factor in their synthesis and storage in the cell.
W. D. H.

Action of Acids in the Enzymic Decomposition of Oil by Castor Oil Seeds. YOSHIO TANAKA (*J. Coll. Eng. Tōkyō*, 1910, 5, 25—42. Compare Armstrong, Abstr., 1906, i, 126).—Castor oil seeds only hydrolyse fats after acid is added. The absolute quantity of the added acid is the important factor, its concentration having no marked influence. The optimum amount of acid required is related to the amount of castor oil seeds alone, and not to the quantity of oil. In the case of mineral and strong organic acids, the optimum quantities

are proportional to their equivalent weights, with weaker organic acids they are larger. The optimum quantity of an acid of the acetic series increases the higher the homologue is; the inhibitory action of an acid when present in excess is greater the lower the homologue.

Lipase is present in castor oil seeds in the form of an insoluble zymogen, which is readily converted by dilute acid into the insoluble enzyme. The added acid does not act by acidifying the medium, but by liberating enzyme from its zymogen. After treating castor oil seeds with acid and completely washing out all the acid and soluble matter with water, a residue was obtained which hydrolysed fatty oils in neutral solution. This proves lipase to be insoluble and active in a neutral medium. It is less active in the presence of free acid, and inactive in an alkaline medium.

E. F. A.

Filtration of Rennet and Pepsin. CASIMIR FUNK and ALBERT NIEMANN (*Zeitsch. physiol. Chem.*, 1910, 68, 263—272).—A complete parallelism between the actions of the two enzymes rennet and pepsin was found; they behaved exactly in the same way in attempts to separate them by Holder's filtration method.

W. D. H.

Inactivation of Rennet by Shaking. SIGNE SCHMIDT-NIELSEN and SIGVAL SCHMIDT-NIELSEN (*Zeitsch. physiol. Chem.*, 1910, 68, 317—343. Compare this vol., i, 83).—A solution of rennet inactivated by shaking recovers its activity after about an hour. The cause of the inactivation is the concentration of the enzyme on the surface of the froth; on remaining quiet, the former condition of things once more obtains. If the froth is removed after shaking, reactivation does not occur in the residual fluid. There is never a complete return of activity, part of the enzyme disappearing; the non-reversible part of the inactivated rennet increases the longer the shaking is continued; this is regarded as an adsorption phenomenon.

W. D. H.

The Milk-curdling and Proteolytic Action of the Gastric Infusion of Ox and Calf and of Natural Gastric Juice. A. RAKORZY (*Zeitsch. physiol. Chem.*, 1910, 68, 421—463).—The milk-curdling enzyme spoken of as chymosin is not identical with pepsin; the former is easily destroyed by incubating at 40° with dilute hydrochloric acid. The two enzymes can also be separated by dialysis, pepsin being almost completely precipitated, whilst the chymosin remains mainly in solution. Chymosin can be extracted from the stomach with water or very dilute hydrochloric acid; a stronger acid then dissolves out the pepsin. The milk-curdling power of gastric juice is due partly to chymosin, partly to pepsin. The amount of the former enzyme lessens with age, so that in the ox the milk-curdling power is due to pepsin alone. Bang's parachymosin is possibly identical with pepsin.

W. D. H.

Theory of the Action of Oxydases. ALEXIS BACH (*Arch. Sci. phys. nat.*, 1910, [iv], 30, 152—164).—A polemical summary of

the rival theories of the action of oxydases of Bertrand and of Bach. Colloidal aluminium hydroxide and, to a less extent, other aluminium salts accelerate the transformation of the red oxidation product, produced by the action of tyrosinase on tyrosine, into black melanin. Laccase acting on pyrogallol produces a yellow coloration; the solution in time becomes reddish-brown, and deposits crystals of purpurogallin. The addition of a few drops of a solution of an aluminium salt at the yellow stage greatly facilitates the formation of purpurogallin, and the rate of oxidation is the same in a portion of the solution which was boiled to destroy the oxydase. The influence of metallic salts on oxydases is analogous to that of ferrous sulphate on peroxides; the salts are only enabled to act because the oxydase has formed a peroxide. Inorganic salts are not an integral part of oxydases, and do not constitute their active principle; their function is solely to accelerate the oxidising action of the peroxides formed by the true oxydases.

E. F. A.

Peroxydase Character of Oxyhæmoglobin. JULES WOLFF and E. DE STOEKLIN (*Compt. rend.*, 1910, 151, 483—485. Compare Abstr., 1908, i, 490, 573, ii, 1022; 1909, i, 347).—The authors have indicated previously the resemblance between certain colloidal compounds of iron and the peroxydases of vegetable origin. Oxyhæmoglobin is now shown to share this similarity, and it has been found by quantitative experiments on the oxidation of potassium iodide, in the presence of hydrogen peroxide, that its catalytic activity surpasses that of the plant peroxydases. It is extremely sensitive to the influence of other substances in the medium, and loses its activity when the solution is boiled. The best results were obtained in an N/20 solution of sodium citrate; small quantities of organic acids inhibit the action.

Oxyhæmoglobin shows the usual reactions with pyrogallol, guaiacol, and quinol. The substance appears to be more active after a second crystallisation than after the first.

W. O. W.

Isomerisation of Some Phosphorus Compounds. I. ALEXANDER E. ARKUSOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 395—420).—The esters of phosphoric acid of the type $P(OR)_3$ under the catalytic influence of alkyl halides are capable of being isomerised into the ethers of the type $PRO(OR)_2$. A rise in temperature of 10° doubles the velocity of reaction, which is also greatest with alkyl iodides and least with the chlorides.

Ethers of the general formulæ $PR'(OR)_2$ and $PR_2'OR$ (where R is an aliphatic radicle, and R' any other aliphatic or aromatic radicle) also undergo isomerisation when treated with alkyl halides, being converted into derivatives of quinquevalent phosphorus, $PRR'OOR$ and $O.PRR_2'$ respectively. The velocity of isomerisation is proportional to the mass or concentration of the catalyst, and to the readiness with which the reacting substance forms intermediate additive products; thus the following is the order of the velocity of isomerisation of some of the substances employed: $PR_2'OEt$, $PR'(OEt)_2$, $P(OEt)_3$.

Phenyl chloride, PPhCl_2 , was prepared by a modification of Michaelis' method (this Journ., 1873, 1148; 1874, 168), a detailed description and figure of the modified apparatus being given; when this substance is heated in a sealed tube at 300° , diphenylphosphoryl chloride, Ph_2PCl , is obtained, which, on treatment in ethereal solution with sodium ethoxide, furnishes *ethyl diphenylphosphinite*, $\text{PPh}_2\cdot\text{OEt}$, b. p. $179^\circ/14$ mm., D_4^{20} 1.0896; the *additive product* with copper iodide has m. p. $190-191^\circ$. As a by-product in the formation of the ester, diphenylphosphinic acid, $\text{PPh}_2\cdot\text{O}\cdot\text{OH}$, is obtained. Under the catalytic influence of ethyl iodide at the ordinary temperature, the ester is converted quantitatively into diphenylethylphosphine oxide, $\text{O}\cdot\text{P}(\text{Et})\text{Ph}_2$.

Isopropyl diphenylphosphinite, $\text{PPh}_2\cdot\text{OPr}^i$, has b. p. $160^\circ/8$ mm., D_4^{20} 1.0925, and forms a crystalline *additive* compound with copper iodide, m. p. $114-115^\circ$. *Isopropyl diphenylphosphinate*, $\text{PPh}_2\cdot\text{O}\cdot\text{OPr}^i$, m. p. $95-96^\circ$, is formed as by-product in the preparation of the ester.

On heating at 115° with isopropyl iodide, isopropyl diphenylphosphinite is quantitatively isomerised into *diphenyl isopropylphosphine oxide*, $\text{O}\cdot\text{P}(\text{Pr}^i)\text{Ph}_2$, which crystallises in prisms, m. p. $145-146^\circ$.

Isobutyl diphenylphosphinite, $\text{PPh}_2\cdot\text{OC}_4\text{H}_9$, has b. p. $202-203^\circ/11$ mm., D_4^{20} 1.0311, and forms a crystalline *additive* compound with copper iodide. In the preparation of the ester, *isobutyl diphenylphosphinate*, $\text{PPh}_2\cdot\text{O}\cdot\text{OC}_4\text{H}_9$, m. p. 77° , and diphenylphosphinic acid are also obtained. *Isobutyl diphenylphosphinite*, when heated at 120° with isobutyl iodide, is isomerised to *diphenylisobutylphosphine oxide*, $\text{O}\cdot\text{P}(\text{H}_2\text{C}\cdot\text{C}_3\text{H}_7)\text{Ph}_2$, which forms needles, m. p. $137.5-138^\circ$.

Diphenylmethylphosphine oxide, $\text{O}\cdot\text{P}(\text{MePh})_2$, prepared from diphenylphosphoryl chloride and sodium methoxide, crystallises in needles, m. p. $109-110^\circ$, and diphenylmethylphosphine is formed as a by-product. The intermediate ester was not obtained, as it isomerises so rapidly. Similarly, *diphenylbenzylphosphine oxide*, m. p. $192-193^\circ$, is obtained from diphenylphosphoryl chloride and sodium benzyloxide. Diethyl phenylphosphinite, $\text{PPh}(\text{OEt})_2$, in contact with ethyl iodide is isomerised into *ethyl phenylethylphosphinate*, $\text{PEtPhO}\cdot\text{OEt}$, b. p. $162-164^\circ/16$ mm. On hydrolysis, *phenylethylphosphinic acid*,

m. p. $79-80^\circ$, is formed, of which the barium and silver salts are described.

Z. K.

Preparation of Amino-derivatives of Hydroxyarylsarsinic Acids and Their Reduction Products. FARBERKE VORM. MEISTER, LEIGES & BRÜNING (D.R.-P. 224953. Compare Abstr., 1909, i, 347).—It is found that the therapeutically active hydroxyarylsarsinic acids can be nitrated, and subsequently reduced to the corresponding amino-compounds having enhanced medicinal value.

Nitrophenolsarsinic acid is prepared by dissolving sodium *p*-hydroxyphenylarsinite (144 parts) in 450 c.c. of concentrated sulphuric acid, and slowly dropping in a mixture of 39 c.c. of nitric acid ($D_{1.4}$) with an equal volume of concentrated sulphuric acid, with continual stirring and at a temperature of 0° ; the mixture is diluted with 1250 c.c. of

water, from which the product separates as a yellow powder. The alkali salts are readily soluble in water, yielding deep yellow solutions.

Aminophenolarsinic acid is prepared by the reduction of the foregoing nitro-compound with either sodium amalgam or sodium hyposulphite; it forms minute prisms or leaflets, which blacken and decompose at about 170° .

Diaminoarsenophenol, a yellow powder, is formed by the energetic reduction of nitrophenolarsinic acid with a large excess of sodium hyposulphite; by oxidation with hydrogen peroxide, it is converted into aminophenolarsinic acid.

Nitro-o-cresolarsinic acid, $\text{OH}\cdot\text{C}_6\text{H}_4\text{Me}(\text{NO}_2)\cdot\text{AsO}_3\text{H}_2$, prepared from *o*-cresolarsinic acid, is a yellow, crystalline powder, sparingly soluble in cold, readily in hot, water.

Amino-o-cresolarsinic acid is exceedingly soluble in water.

Diaminoarsenocresol, m. p. $165-167^{\circ}$ (decomp.), is sparingly soluble in water and in organic solvents.

Dinitrophenolarsinic acid is prepared by the action of excess of nitric acid (D 1.5) with concentrated sulphuric acid on *p*-hydroxyphenylarsinic acid at a temperature of $15-20^{\circ}$; it forms dark yellow leaflets, sparingly soluble in cold, readily in hot, water.

Diaminophenolarsinic acid, silver grey needles, decomposes at about 170° without fusion.

Tetraminoarsenophenol, a bright yellow powder which blackens and decomposes at about $155-157^{\circ}$, is obtained by the reduction of dinitrophenolarsinic acid with a large excess of sodium hyposulphite.

F. M. G. M.

Preparation of Pyrimidine Derivatives containing Mercury.
FARBENFABRIKEN VORM. FRIEDRICH BAYER & Co. (D.R.-P. 224491).—

When the alkali salt of 4-imino-2:6-diketodihydropyrimidine-3-acetic acid, $\text{CO}\langle\text{NH}-\text{CO}\rangle\text{CH}_2\cdot\text{C}(\text{NH})\rangle\text{N}\cdot\text{CH}_2\cdot\text{CO}_2\text{Na}$, is shaken in aqueous suspension with freshly precipitated mercuric oxide or mercury acetamide during several hours, the solution filtered, concentrated in a vacuum, and treated with alcohol, a compound,

is obtained. It is insoluble in organic solvents, but readily soluble in water, and from which mercury is not precipitated on the addition of sodium carbonate.

F. M. G. M.

Organic Chemistry.

Molecular Rearrangements of Carbon Compounds. C. G. DERICK (*J. Amer. Chem. Soc.*, 1910, 32, 1333—1350).—A general paper of a theoretical character, dealing especially with rearrangements of the non reversible type, such as the transformation of Δ^2 -unsaturated acids into their Δ^2 -isomerides. A discussion is given of the formation, stability, and velocity of rearrangement of compounds of this class, and a system of classification of molecular rearrangements of organic compounds is presented. E. G.

Wax Oil. THOR EKECRANTZ and E. LUNDSTRÖM (*Arch. Pharm.*, 1910, 248, 500—513).—At the present time wax oil (*oleum ceræ*) is always prepared by the dry distillation of wax and calcium oxide. The authors have examined wax oil obtained by three different methods: (A) pure beeswax and twice its weight of calcium oxide are distilled in an iron retort, the distillate being rectified by two distillations with twice the quantity of calcium oxide; (B) equal weights of beeswax and calcium oxide are distilled in a glass retort on a sand-bath, the distillate being rectified by a second distillation with an equal weight of calcium oxide; (C) wax oil prepared in an apothecary's laboratory, and guaranteed unadulterated. A is a greyish-yellow mass of crystalline leaflets, and has m. p. 34.5° , D_{20}^{25} 0.792, acid number 15.4, and iodine number 68.3. B is a brownish-yellow oil, having D_{20}^{25} 0.792, acid number 8.7, and iodine number 84.3. C is also a brownish-yellow oil, having D_{20}^{25} 0.790, acid number 9.7, and iodine number 86.6. The oils are distilled with steam, and the residues are separated by acetone into a liquid and a solid portion; from the proportions of the liquid volatile with steam, the liquid non-volatile with steam, and the solid, it is evident that in the distillation of wax and calcium oxide the decomposition of the initially-formed products is least in the oil prepared by method A and greatest in that prepared by method B. The liquid volatile with steam consists chiefly of a mixture of saturated and unsaturated hydrocarbons, containing 10—16 atoms of carbon; the non-volatile liquid, of a similar mixture containing 16—27 atoms of carbon. The solid portion, m. p. $58-59^\circ$, iodine number 13.1, is separated by ether into two parts; one, sparingly soluble in ether, consists chiefly of nonacosane and a little myricyl alcohol; the other, easily soluble in the solvent, is probably a mixture of nonacosane, pentacosane, and a small quantity of unsaturated hydrocarbons. Several commercial wax oils have also been examined. The authors state that the sp. gr. of a wax oil should lie between 0.790 and 0.792, the acid number between 8 and 12, and the iodine number between 80 and 90. They recommend that the iodine number should be determined in the liquid constituents which are volatile with steam. C. S.

Additive Power of 2-Pentene [Δ^2 -Amylene]. ROGER F. BRUNEL and EUGENE G. PROBECK (*Amer. Chem. J.*, 1910, 44, 5, 431—438. Compare Michael, *Abstr.*, 1909, i, 197).—A comparison

is given of the additive power of Δ^{β} -amylenes towards acid with that of β -methyl- Δ^{β} -butylene and of α -butylene. Michael's hypothesis regarding the relation between the position of atoms in a molecule and their influence on each other is adopted (Abstr., 1900, i, 321; 1906, i, 550). According to this hypothesis, if one of the unsaturated carbon atoms in the molecule be numbered 1, the mutual influence between this atom and the other atoms of the molecule will decrease according to the scale: 2—3—5—6—4—7—(9—10—11)—8.

In the case of Δ^{α} -butylene and Δ^{β} -amylenes this gives:

By an additive process the unsaturated atoms in each molecule are compared, and it is shown that from this consideration alone, the greater additive power should be found in the case of Δ^{β} -amylenes, although the difference should not be great. As, however, with the transition from the C_4 to the C_5 series the reduction in the affinity for hydrogen increases, there is a possibility that Δ^{β} -amylenes may show the weaker additive power. This is found experimentally to be the case, the ratio being about 7:5. A similar comparison with β -methyl- Δ^{β} -butylene shows that the difference in additive power in this case must only depend on the degree of attraction of the negative radicals. Experimentally the velocity with which β -methyl- Δ^{β} -butylene dissolves in dilute sulphuric acid is over one hundred times as great as for Δ^{α} -amylenes.

The Adsorption of Acetylene by Colloidal Palladium. CARL PAAL and CHRISTIAN HOHENEGGER (*Ber.*, 1910, 43, 2684—2692).—The liquid hydrosol of palladium, prepared according to the method of Paal and Amberger, dissolves considerable quantities of acetylene. The determination of the amount adsorbed was made in a way similar to that used by Paal and Gerum (Abstr., 1908, ii, 392) to measure the adsorption of hydrogen.

Several days are necessary before the adsorption is complete. After adsorption is complete at room temperature, warming at 40—70°, accompanied by the exercise of a slight pressure, increases the amount of acetylene adsorbed. This extra acetylene is not liberated when the original temperature and pressure are restored, since it is converted partially into volatile and non-volatile condensation and polymerisation products, which, however, could not be isolated in sufficient quantity for identification.

On exposing a palladium hydrosol which has been saturated with acetylene to the air, the chemically unchanged acetylene is set free, especially on warming. On bringing the palladium sol again into contact with acetylene, very little gas is adsorbed, probably because the palladium particles are coated with the acetylene condensation products. This is also the case when the palladium sol is extracted with ether, acidified in order to precipitate the adsorption compound of the solid palladium sol with free protalbic acid, and the precipitate again converted into a liquid sol by the addition of water containing a little sodium hydroxide.

The number of molecules of acetylene adsorbed per gram-atom of

palladium varied from 0.44 to 1.90 molecules, namely, from 1075 to 4630 volumes of acetylene per one volume of palladium, depending on the duration of the experiment and the concentration of the palladium.

T. S. P.

The Adsorption of Acetylene by Palladium Black. CARL PAAL and CHRISTIAN HOHENEGGER (*Ber.*, 1910, 43, 2692—2694).—The adsorption of acetylene by palladium black was measured in an apparatus similar to that used by Paal and Gerum (*Abstr.*, 1908, ii, 372) to determine the adsorption of hydrogen. The palladium was suspended either in an aqueous solution of sodium protalbate or in an aqueous solution of ammonia, or in aqueous alcohol, in order to determine whether the acetylene adsorbed by the palladium reacted with the dissolved substances. In all three cases, approximately equal quantities of acetylene were adsorbed (1.36—1.53 molecules per gram-atom of palladium); in no case did the adsorption exceed that obtained with colloidal palladium under similar conditions.

Some of the adsorbed acetylene was changed into condensation products, but not to the same extent as with colloidal palladium.

T. S. P.

Tetranitromethane. ERNEST BERGER (*Compt. rend.*, 1910, 151, 812—815. Compare Pictet and Gœuquand, *Abstr.*, 1903, i, 303, 356; Chittaway, *Trans.*, 1910, 97, 2099).—The following method is recommended for the preparation of tetranitromethane. A mixture of 160 grams of absolute nitric acid (or 180 grams of fuming nitric acid) with glacial acetic acid (100 grams) is treated, in a flask kept cool under the tap, with acetic anhydride (290 grams). The flask is allowed to remain in cold water for some hours, and then for a night at the ordinary temperature. After heating for three to four hours at 25—30°, the temperature is raised by 5° every three to four hours until it reaches 65—70°, when the liquid is poured into four times its volume of water. The tetranitromethane is washed and dried over anhydrous sodium sulphate; the acid liquid from which it separates contains trinitromethane and trinitroacetic acid. The yield is 28—60 grams, according to the concentration of the nitric acid.

Tetranitromethane has b. p. 21—23°/22 mm., 124—125°/750 mm. with slight decomposition; D_{20}^{22} 1.620. The heat of combustion was determined in presence of amyl alcohol, since the compound itself contains too much oxygen. The results are expressed by the equations: $C(NO_2)_4 = CO_2 + 2N_2 + 3O_2 + 89.6 \text{ Cal.}$ C diamond + $2N_2(\text{gas}) + 4O_2(\text{gas}) = C(NO_2)_4 + 4.7 \text{ Cal.}$

W. O. W.

Catalytic Reactions by means of Metallic Oxides. ALPHONSE MAILHE (*Chem. Zeit.*, 1910, 43, 1173—1174, 1182—1184, 1201—1204).—In these three papers a résumé is given of the results of recent work carried out by the author and others on the catalytic reactions induced by heated metallic oxides. The first paper deals with the decomposition of alcohols, acids, and esters, and records, for the most part, results already published (Senderens, *Abstr.*, 1907, i, 577; 1908, ii, 166; i, 494, 495; 1909, i, 127, 286, 627; and this vol., i, 11, 179, 318, 489; Sabatier and Mailhe, 1908, i, 594, 713; 1909, i, 546, and this vol., i, 294, 606). In the second paper a theory of these catalyses already outlined (*loc. cit.*, but especially 1908, i, 594, and this vol., i,

294) is discussed in detail in its application to various special cases, and the preparation of amines is described (Abstr., 1909, i, 292), with a number of new examples of the application of the process to this class of compounds. The third paper deals with the preparation and decomposition of thiols by this process (this vol., i, 294, 456, 536).

T. A. H.

Two Active Alcohols and a Third Ketone Contained in Coconut Oil. ALBIN HALLER and A. LASSIZUR (*Compt. rend.*, 1910, 151, 697—699. Compare this vol., i, 355).—The odoriferous constituents of the "essence" of coconut butter have been shown previously to consist of higher fatty acids with neutral substances. The latter have now been separated into alcohols and ketones by means of phthalic anhydride. The alcoholic portion consists chiefly of *d-methylnonylcarbinol*, b. p. 228—233°, D_4^{20} 0.827, n_{20}^{25} 1.4336, $[\alpha]_D^{25}$ +1.24°, with a small quantity of *d-methylheptylcarbinol*, b. p. 195—196°, D_4^{20} 0.823, n_{20}^{25} 1.4249, $[\alpha]_D^{25}$ +2.25°. The ketonic portion contains about 75% of methyl nonyl ketone, together with methyl heptyl ketone and methyl undecyl ketone.

W. O. W.

Basic Properties of Oxygen: Compounds with Bromine and Iodine. DOUGLAS MCINTOSH (*J. Amer. Chem. Soc.*, 1910, 32, 1330—1333).—It has been suggested by Tschelinzeff and Konowaloff (Abstr., 1909, i, 353) that the compound $C_4H_{10}OBr_2$, obtained by the action of bromine on ethyl ether, has the constitution $C_4H_{10}O \begin{smallmatrix} Br \\ \diagup \\ \diagdown \\ Br \end{smallmatrix}$.

It is now stated that the compound obtained by these authors was not pure, and that the value of the molecular weight in acetic acid which they obtained is not trustworthy, since the dibromide is decomposed by this solvent. Attempts have been made to determine the molecular weight of the di- and tri-bromides of ethyl ether by f. p. measurements in chloroform solution, but without success, since the substance undergoes partial decomposition under those conditions. It has also been found that this constant cannot be determined by Ramsay and Shields' method.

Waentig (this vol., ii, 117) has stated that iodine combines with certain organic solvents at low temperatures. It is now found that when a solution of iodine in alcohol or acetone is cooled to -80° or -90°, a substance separates which may be mistaken for a compound. When completely dried at a low temperature, however, the product is shown by analysis to be iodine, contaminated with a little of the solvent. When ethyl acetate is used, mixed crystals of the solvent and iodine may be obtained.

When bromine and chlorine are dissolved in organic solvents containing oxygen, an appreciable amount of heat is developed, whilst, in the case of iodine, a slight absorption of heat occurs. On the basis of these facts, it is shown that it is improbable that iodine compounds could be produced in a reasonably pure state by cooling the solutions to a low temperature.

E. G.

The Solubilities of the Pharmacopœial Organic Acids and Their Salts. ATHERTON SEIDELL (*Bull. No. 67, Hyg. Lab., U.S. Pub. Health and Mar. Hosp. Serv.*, 1910, 7—98).—The importance attached

to the quotation of solubility determinations in pharmacopœial descriptions of chemicals has led the author to re-determine the solubilities of the organic acids of the United States Pharmacopœia in water, aqueous alcohol, and a number of common organic solvents, and to obtain like data for the official salts of these acids as regards water and aqueous alcohol. The results obtained, together with obviously trustworthy results recorded by previous investigators, are tabulated, and also represented graphically in the original.

The method used consisted in agitating the solvent with excess of the acid or salt at the selected temperature, due precautions being taken to secure saturation in each case and to ensure uniform experimental conditions. The specific gravity of the saturated solution was determined, and then the quantity of substance in solution ascertained by evaporation to dryness, or if this was impossible, by chemical analysis. The results are expressed as the number of grams of substance in 100 grams of the saturated solution.

The following deductions are drawn from a consideration of all the results obtained. Of the thirty-five substances examined, only nine gave results showing satisfactory agreement with the figures quoted in the U. S. P., the remainder showing differences ranging from 5 to 190%. A solubility determination is of little value as a criterion of the purity of a substance. It is impossible to predict the solubility of a substance in a mixture of alcohol and water from a knowledge of its solubility in each of these solvents alone. Citric acid shows nearly parallel solubility curves for the anhydrous and hydrated forms in aqueous alcohol, the second being the more soluble substance. Potassium citrate mixed with aqueous alcohol causes the separation of an upper layer of nearly pure alcohol, and a lower layer of aqueous salt solution (compare Linebarger, Abstr., 1892, 1146). Oleic acid shows apparently unstable solubility equilibrium in aqueous alcohol at certain concentrations. Trichloroacetic acid undergoes partial esterification in aqueous-alcoholic solutions.

T. A. H.

Organic Salts of Yttrium. SEBASTIAN TANATAR and I. VOLZANSKI (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 586—590).—Yttrium propionate, $(EtCO_2)_3Y$, formed by the prolonged heating on a water-bath of yttrium oxide with dilute propionic acid, can be readily obtained pure by recrystallisation. It forms white, monoclinic needles, and is insoluble in all organic solvents except warm alcohol, by which, however, it is converted into the basic salt. The following salts were also obtained: the isobutyrate, $(C_3H_7\cdot CO_2)_3Y$; lactate, $(OH\cdot CHMe\cdot CO_2)_3Y, 4H_2O$; benzoate, $Y(OBz)_3$; fumarate, $(C_4H_3O_3)_3Y, 2H_2O$; phthalate, $(C_8H_4O_4)_3Y, 2C_{10}H_8O_4$; crotonate, $(CHMe\cdot CH\cdot CO_2)_3Y, 5H_2O$; malate, $(C_4H_4O_5)_3Y$; and citronate, $(C_6H_4O_4)_3Y, 9H_2O$.

Yttrium nitrate, $Y(NO_3)_3\cdot 2H_2O$, is formed by dissolving yttrium oxide in excess of dilute nitric acid and evaporating to a syrup, which is dried at 100° . After cooling and stirring, the syrup suddenly forms tiny crystals with development of heat.

Z. K.

Transformation of Stereoisomeric Ethylenic Compounds. I. PAUL PFEIFFER (*Ber.*, 1910, 43, 3039—3048).—When an $\alpha\beta$ -di-haloid derivative of butyric or β -phenylpropionic acid is treated with potassium hydroxide, it furnishes the unstable corresponding α -halogenated *isocrotonic* or *allocinnamic* acid, whereas with pyridine it yields the stable α -halogenated isomeride. In both cases the unstable form is first produced, but in the presence of pyridine this is transformed into its isomeride.

[With A. LANGENBERG].— $\alpha\beta$ -Dichlorobutyric acid reacts slowly with pyridine at the ordinary temperature, but more rapidly on warming at 100°, to give α -chlorocrotonic acid. Under like conditions, $\alpha\beta$ -dibromobutyric acid furnishes α -bromocrotonic acid. $\alpha\beta$ -Dichloro- β -phenylpropionic acid is not decomposed by pyridine at atmospheric temperature, but at 100° furnishes α -chlorocinnamic acid, whilst $\alpha\beta$ -dibromo- β -phenylpropionic acid gives cinnamic with some α -bromocinnamic acid.

α -Chloroisocrotonic acid, when kept in pyridine solution with pyridine hydrochloride at atmospheric temperature, or more rapidly on warming, is converted into α -chlorocrotonic acid, and under like conditions a similar change ensues with α -chloro*allocinnamic* acid, α -bromo*allocinnamic* acid, and α -bromoisocrotonic acid, the last-mentioned acid being also transformed when kept with pyridine alone. β -Chloroisocrotonic acid is not transformed into β -chlorocrotonic acid under these conditions.

T. A. H.

Linolenic Acid and Linseed Oil. ERNST ERDMANN and FRED BEDFORD (*Zeitsch. physiol. Chem.*, 1910, 69, 76—84. Compare Abstr., 1909, i, 357).—Several miscalculations are pointed out in Rollett's work (*Abstr.*, 1909, i, 760). The general conclusions drawn are: (1) The hydrogen and iodine numbers show that in linseed oil there is not more than 20—25% of acids, $C_{18}H_{30}O_2$, containing three ethylene linkings. This is mainly α -linolenic acid, which yields a hexabromide, m. p. 179°. (2) When the solid hexabromide is treated with zinc, a mixture of two stereoisomeric acids is formed; 75% of this mixture consists of β -linolenic acid and 25% of the α -acid. The β -acid yields an oily tetrabromide, and this with zinc gives the β -acid together with polymerisation and anhydro-products. (3) Rollett's conclusions that only one linolenic acid is present in linseed oil, and that the amount is some 50—60%, are incorrect.

J. J. S.

The Composition of Boiled Linseed Oil and the Distribution of Oxygen in Dried Layers of Oil. I. E. I. ONLOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 658—676. Compare Erdmann, *Abstr.*, 1909, i, 357).—The solid substances formed when linseed oil is dried on a plate contain unsaturated double linkings, and even when the greatest quantity of oxygen has been absorbed, the dried oil still gives an iodine number not less than 14.15. The amount of oxygen absorbed depends on the thickness of the layer and the surrounding temperature, but in all cases if, after the layer has ceased to increase in weight, the surface of the layer be removed, oxygen commences to be absorbed again and the weight increases.

Although fresh linseed oil has no reducing properties, the oil dried on plates is markedly reducing, owing to the formation of two *linoxins* from the glycerides of linolic and linolenic acid.

The *linoxin* (I) from linolenic acid is a solid insoluble in alcohol and ether, that (II) from linolic acid is a soluble syrupy liquid. The *linoxins* are not ozonides, and a detailed study of their properties leads to the conclusion that they have the following constitution :

The relative proportions of each formed in various experiments are estimated and found to agree very well with the theoretically calculated numbers. Z. K.

The Ability of Alcoholic Hydroxyl Groups to Form Complexes. G. CALCAGNI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 833-337).—By a method analogous to that of Weinland (*Abstr.*, 1909, i, 757), the author has prepared basic salts of hexaglycollato- and hexalactato-trichrome bases. To them is to be assigned a constitution similar to that of the salts obtained by Weinland, so that in this case the alcoholic hydroxyl groups take part in the formation of the salt, whilst other negative radicles (chlorine, bromine) only strengthen the carboxylic hydrogen. The *basic glycollate* of a *hexaglycollatotrichrome base*, $\left[\text{Cr} \left(\text{CO}_2 \cdot \text{CH}_2 \cdot \text{OH} \right)_6 \right] \text{CO}_2 \cdot \text{CH}_2 \cdot \text{OH}, \text{Cr}(\text{OH})_3$, is obtained as a dark green, hygroscopic powder by dissolving chromic hydroxide in glycollic acid and precipitating with alcohol. It is stable towards ammonia and sodium hydroxide; chromic hydroxide is only precipitated after prolonged ebullition with the latter. The *basic lactate* of a *hexalactatotrichrome base*,

was obtained in the same way, and has similar properties. The analytical results indicate the presence of about $5\text{H}_2\text{O}$ in the molecule. When it is treated with fuming nitric acid on the water-bath, only one of the lactate groups is replaced, the *nitrate*,

being formed.

R. V. S.

The Equilibrium Isomerism of Acetoacetic Ester and the So-called Isorropesis of its Salts. ARTHUR HANTZSCH (*Ber.*, 1910, 43, 3049-3076).—A systematic investigation of acetoacetic ester and its homologues has been made both by refractometric (compare Brühl, *Abstr.*, 1905, i, 407) and ultra-violet absorption spectra methods, with a view to determining its constitution. The following are the chief results recorded.

The dialkylacetoacetates, which exist only in the ketonic form, absorb but little ultra-violet light, whilst ethyl ethoxycrotonate shows large absorption, but neither of these exhibits much change in absorption in whatever solvent it is examined. Ethyl acetoacetate, on the contrary, shows great variation in absorption, depending on the solvent used; thus, in water and dilute hydrochloric acid, it is slightly absorbent, whilst in indifferent solvents the absorption increases inversely as the dielectric constant of the solvent, and reaches its maximum in hexane. The absorption also increases with rise of temperature and with increasing dilution, the latter especially in hexane. This rise in absorptive capacity is parallel with Brühl's exaltation of refraction. Methyl- and ethyl-acetoacetic esters show similar behaviour. Homogeneous ethyl acetoacetate shows greater absorption than its solutions.

Tables and graphs illustrating these general results are given in the original.

The following explanation of these results is given. The acetoacetates and their mono-substitution products, in the homogeneous state and also in solution in indifferent solvents, are equilibrium mixtures of keto-enolic isomerides. The equilibrium point is shifted to the enol side by (1) rise of temperature, (2) dilution in the same solvent, (3) use of solvents of decreasing dielectric constant. Ethyl acetoacetate is strongly enolised and slightly associated. In dilute hydrochloric acid solution, it is practically entirely ketonised, and in dilute hexane solution almost entirely enolised, since then it shows nearly the same absorption spectrum as ethyl ethoxycrotonate. In water, at medium temperatures, it is about one-fifth, and in methyl alcohol about nine-tenths, enolised. These results are confirmed in part by Stobbe's observations on the ferric chloride test (Abstr., 1907, i, 177).

It is pointed out that the phenomenon of isorropesis (Stewart and Baly, Trans., 1906, 89, 498) is particularly well shown by the addition of alkalis to ethyl acetoacetate (compare Baly and Desch, *ibid.*, 1904, 85, 1036), and is probably the result of "salt" formation, since maximum absorption is reached more quickly the greater the concentration of ester and the more acidie in nature the latter is. Further, the metallic derivatives of ethyl acetoacetate are optically and chemically different from the enol-form of the ester itself, and in these derivatives the ester must exist in a new form, which may be called the aci-form, since it probably also occurs to a minute extent in solutions of the ester in hexane. The relationship of the aci- and enol forms cannot be that of stereoisomerides, as these would be optically identical (this vol., i, 474), and of the formulæ considered for the aci-form, the most likely is the annexed one, the dotted line indicating a "subsidiary valency." This formula represents a "valency isomeride" of the enol form and permits

in a modified way of Baly and Desch's "oscillation" explanation of isorropesis, the oscillation taking place by an interchange of "principal" and "subsidiary" linkings at the points marked 1 and 2, with a suitable change in position of the double linkings. Apart from the equilibrium isomerism

between the keto and enol forms and between the enol and aci-forms, there is a third possible equilibrium between the trans-enol and cis-enol forms, and it seems likely that the cis-enol form only can pass into the aci-form thus:

Ethyl α -Nitrosoisheptoate and the Action of Nitrous Gases on Allyl-, Dimethyl-, and Diethyl-acetoacetic Esters. JULIUS SCHMIDT and AUGUST HAID (*Annalen*, 1910, 377, 23–30. Compare Schmidt and Widmann, Abstr., 1909, i, 453).—The nitrous gases from a mixture of nitric acid and arsenious anhydride react with ethyl isheptoate, yielding *ethyl α -nitrosoisheptoate*,

as a dark blue oil, $D_4^{20.2}$ 1.054, and $n_D^{20.2}$ 1.6251. It has a strong odour, cannot be distilled even under very low pressures, and gives Liebermann's nitroso-reaction. When kept or when treated with water or alkalis, the blue liquid becomes colourless; this is partly due to polymerisation, and partly to conversion into the isomeric oximino-derivative. It has a deeper colour, and is also somewhat more stable than the analogous isohexoate (Schmidt and Widmann). When oxidised with hydrogen peroxide, the nitroso-ester yields *ethyl α -nitroisheptoate*, $\text{CHMe}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}(\text{NO}_2)\cdot\text{CO}_2\text{Et}$, as a yellow oil, D_4^{20} 1.070, n_D^{20} 1.4486.

The nitrous gases react with ethyl allylacetacetate, but definite products could not be isolated, and when ethyl dimethyl- and diethyl-acetacetates were used, the unaltered esters were recovered. It would thus appear that substituted acetoacetic esters, in which both the methylene hydrogens are replaced by alkyl groups, cannot yield nitroso-derivatives.

J. J. S.

Esters of Aliphatic Nitroso- and Nitro-carboxylic Acids. JULIUS SCHMIDT and HEDWIG DIETERLE (*Annalen*, 1910, 377, 30–70. Compare Schmidt and Widmann, Abstr., 1909, i, 453; Schmidt and Haid, preceding abstract).—Nitrous gases from arsenious anhydride and nitric acid are able to replace by nitroso-groups, not merely acetyl, but also formyl and benzoyl groups in esters of α -acylated saturated carboxylic acids. The formyl group is replaced most readily, and the benzoyl group least readily. In the last case the reaction requires several days for completion, and the product actually isolated is not a true nitroso-derivative, but the isomeric oximino-compound; at the same time, partial hydrolysis occurs, so that the final product in the case of ethyl benzoylsuccinate is ethyl hydrogen oximinosuccinate, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{C}(\text{NOH})\cdot\text{CO}_2\text{Et}$.

The nitro-group in esters of nitro-substituted saturated acids can also be replaced by the nitroso-group by the action of the nitrous gases on the ester in the absence of a solvent, but it has not been found possible, so far, to replace the bromine atom in α -brominated

esters by the nitroso-group. When ethyl formylphenylacetate is used, an oximino-group replaces the formyl group, and at the same time the phenyl radicle is nitrated, so that the final product is

Ethyl diacetylacetate does not react with the nitrous gases; the presence of a CH-group in the acylated ester is thus essential for the reaction (compare preceding abstract), and it is probable that the nitroso-group first replaces the hydrogen atom of this group and that hydrolysis then takes place, resulting in the elimination of a molecule of the organic acid, for example: $\text{CH}_3 \cdot \text{CO} \cdot \text{CH}(\text{NO}) \cdot \text{CO}_2\text{Et} \rightarrow \text{CH}_3 \cdot \text{CO} \cdot \text{C}(\text{NO})\text{R} \cdot \text{CO}_2\text{Et} \rightarrow \text{CH}_3 \cdot \text{CO}_2\text{H} + \text{NO} \cdot \text{CHR} \cdot \text{CO}_2\text{Et}.$

The changes which the nitroso-derivatives undergo when kept have been examined, mainly by cryoscopic measurements. In the case of ethyl α -nitrososuccinate and ethyl α -nitroso *n*-butyrate, the blue oils undergo polymerisation, yielding the nearly colourless bimolecular products, which, in their turn, change gradually into the yellow or colourless, unimolecular oximino-derivatives, for example:

In most other cases the second change begins before the first is complete, so that the molecular weight never reaches the value required for the bimolecular compound. This is extremely well shown in the case of ethyl α -nitrosopropionate, prepared from ethyl α -formylpropionate. The conversion into the oximino-compounds is accelerated to an enormous extent by the presence of minute traces of alkalis, and most solvents, for example, water and benzene, also facilitate the transformation.

Good yields of esters of amino-acids cannot be obtained by reducing either the nitroso- or the more stable nitro-esters, the best results being obtained when stannous chloride and hydrochloric acid are used. Small amounts of the oximino-carboxylic acids can be prepared by hydrolysing the esters of the nitroso acids with very dilute alkali at low temperatures. Small yields of the potassium salts of the α -nitro-acids are formed when the corresponding esters are treated with concentrated potassium hydroxide solution. They form golden-yellow crystals, and cannot be transformed into the corresponding acids.

Ebert's ethyl α -oximosuccinate (Abstr., 1885, 1122) is formed readily when ethyl α -nitrososuccinate is shaken with sodium carbonate solution; it has n_D^{20} 1.3765, and when hydrolysed with sodium hydroxide, the oximino-ester yields oximosuccinic acid, ethyl oximinopropionate, or oxalacetic acid, according to the conditions of the experiment, but in all cases the yields are extremely poor, namely, 1 to 2%.

Ethyl α -nitroso *n*-valerate, $\text{CH}_2\text{Et} \cdot \text{CH}(\text{NO}) \cdot \text{CO}_2\text{Et}$, prepared from ethyl *n*-propylacetoacetate, forms a dark blue oil, and retains the blue colour for some twelve to twenty-four hours at the ordinary temperature. It has D_4^{20} 1.213 and n_D^{20} 1.4350, and the isomeric α -oximino-ester is a yellow oil, with n_D^{20} 1.3250. When oxidised with hydrogen peroxide, the nitroso-derivative yields ethyl α -nitro *n*-valerate, $\text{CH}_2\text{Et} \cdot \text{CH}(\text{NO}_2) \cdot \text{CO}_2\text{Et}$, as a yellow oil, with D_4^{20} 1.0551, n_D^{20} 1.4595, and has a very strong odour.

Ethyl α -nitrosohexoate (Abstr., 1909, i, 454) has n_D^{20} 1.4515, and when the corresponding nitro-derivative is treated with concentrated potassium hydroxide solution, yellow crystals of potassium α -nitrohexoate, $C_6H_{11} \cdot CH(NO_2) \cdot CO_2K$, are formed, together with the potassium salt of α -oximinohexoic acid.

α -Oximinohexoic acid, $C_6H_{11} \cdot C(N \cdot OH) \cdot CO_2H$, crystallises from water in colourless needles, m. p. 132° (decomp.).

Pure ethyl α -nitrosopropionate, prepared from ethyl α -formylpropionate, has n_D^{20} 1.4295, and can be kept for two or three days. The best method for transforming it into the isomeric α -oximino-ester is shaking for a few minutes with very dilute sodium hydrogen carbonate solution and keeping for two to three hours.

Ethyl oximinonitrophenylacetate, $NO_2 \cdot C_6H_4 \cdot C(N \cdot OH) \cdot CO_2Et$, crystallises from alcohol in colourless, glistening needles, m. p. 195°. It yields sparingly soluble mercurous and silver derivatives, and gives a dirty reddish-brown colour with ferric chloride. The benzoyl derivative, $NO_2 \cdot C_6H_4 \cdot C(CO_2Et) \cdot NO \cdot COPh$, has m. p. 145°, and its methyl ether forms colourless needles, m. p. 151°.

It has not been found possible to isolate a nitroso-derivative from ethyl dibenzoylsuccinate by the action of nitrous gases, although benzoic acid is eliminated.

Ethyl α -benzoylpropionate reacts with nitrous gases, yielding ethyl α -oximinopropionate and the corresponding acid (Ebert, *loc. cit.*).

J. J. S.

Synthesis of β -Methyl- $\alpha\beta$ -diethylhydracrylic Acid and its Properties. I. MATSCHUREVITSCH (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 891—899. Compare Abstr., 1909, i, 304).—Ethyl β -methyl- $\alpha\beta$ -diethylhydracrylate [*ethyl β -hydroxy- β -methyl- α -ethylacrylate*],

is best prepared by mixing methyl ethyl ketone with ethyl α -bromobutyrate dissolved in dry benzene, and pouring on to dry zinc previously treated with sulphuric acid. The whole is heated on the water-bath in a reflux apparatus for some hours, after which the product is treated with water, fractionated, and purified. It is a colourless, mobile liquid, b. p. 115.5—116°/25 mm., 214—219°/760 mm. (decomp.), D_4^{20} 0.96230, which with barium hydroxide yields the acid, $OH \cdot CMeEt \cdot CHEt \cdot CO_2H$, of which the potassium, sodium, barium, silver, and copper salts are described.

With sulphuric acid the acid is decomposed, thus:

and $OH \cdot CMeEt \cdot CHEt \cdot CO_2H = H_2O + CO_2 + OH \cdot CMeEt \cdot CH_2Et$.

When the ester is treated with phosphoric oxide, ethyl β -methyl- α -ethyl- Δ^2 -pentenoate, $CMeEt \cdot CH_2Et \cdot CO_2Et$, b. p. about 188—190°, is formed, which when treated with potassium hydroxide yields β -methyl- α -ethyl- Δ^2 -pentenoic acid, $CMeEt \cdot CH_2Et \cdot CO_2H$, of which a bromide and the potassium, silver, lead, and calcium salts were prepared.

The Unary Termolecular Pseudo-ternary System: Acetaldehyde, Paracetaldehyde, and Metacetaldehyde. ANDREAS SMITS and H. L. DE LEEUW (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 318—323).—Observations relating to the connexion between acet-

aldehyde, paracetaldehyde, and metacetaldehyde are discussed, and it is shown that the apparently contradictory results relating to the conditions under which these substances are formed and transformed into one another can be accounted for on the assumption of a ternary equilibrium represented by:

On account of the conversion of metacetaldehyde into the other two isodynamic forms, previous attempts to determine the triple point of metacetaldehyde have given erroneous results. By a method in which the substance, contained in closed thin-walled capillary tubes, was immersed in baths of different temperatures, the melting point of metacetaldehyde under its own vapour pressure was found to be 246.2° . This is much higher than the temperatures, 184° and 167° , obtained by Roozeboom and Hollman respectively. H. M. D.

The System Acetaldehyde-Alcohol. ANDREAS SMITS and H. L. DE LEEUW (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 329—339).—Experiments have been made to determine the nature of the additive compounds which are formed in mixtures of acetaldehyde and ethyl alcohol. Mixtures which had been kept at the ordinary temperature for about a year, or heated for several hours at 100° , gave no indication of the presence of water when tested with anhydrous copper sulphate. When acetaldehyde-alcohol mixtures are left in contact with copper sulphate for a long time, a blue colour appears, however, and this is supposed to be due to the catalytic influence of the copper salt on the formation of acetal. This accelerating effect affords a convenient method for the preparation of acetal.

The mixing of acetaldehyde and alcohol is attended by a large diminution in volume, and it is found that the density of an equimolar mixture has a maximum value (D_{18}° 0.8719) which is very much greater than that of either of the components. The density data indicate therefore the formation of a compound $\text{CH}_3\cdot\text{COH}\cdot\text{C}_2\text{H}_5\cdot\text{OH}$.

Measurements of the boiling points of various mixtures at different pressures, and of the composition of the vapour emitted by these mixtures, were also made. The curves obtained by plotting boiling points against the composition of the liquid also indicate the formation of the above compound, and a further compound containing a larger proportion of alcohol. Similar conclusions are drawn from the heats of mixing, a maximum heat effect being obtained for an equimolar mixture.

The data obtained in freezing-point measurements confirm these results, and indicate with certainty the formation of compounds, $\text{CH}_3\cdot\text{COH}\cdot\text{C}_2\text{H}_5\cdot\text{OH}$ and $\text{CH}_3\cdot\text{COH}\cdot 2\text{C}_2\text{H}_5\cdot\text{OH}$, which are considerably dissociated at their respective melting points, -122° and -133° . H. M. D.

Preparation of Keten from Acetone. JULIUS SCHMIDLIN and MAXIMILIAN BERGMANN (*Ber.*, 1910, 43, 2821—2823. Compare Wilshire, *Trans.*, 1907, 91, 1938).—Keten appears to be stable

at fairly high temperatures, and a 14% yield can be obtained by passing the vapour of acetone through a hard glass tube filled with porous earthenware and heated at 500—600°. The decomposition of acetone appears to take place in two stages: (1) at about 500—600°, $2\text{CH}_3\cdot\text{CO}\cdot\text{CH}_3 = 2\text{CH}_3\cdot\text{CO} + 2\text{CH}_4$, and (2) at higher temperatures, $2\text{CH}_3\cdot\text{CO} = 2\text{CO} + \text{C}_2\text{H}_4$. It is impossible to prevent part of the keten from decomposing even at the lower temperature.

It is highly probable that in the preparation of keten from acetic anhydride, acetone is the first product formed. J. J. S.

A New Sugar, Verbascose, from the Root of Mullein. ÉMILE BOURQUELOT and MARC BRIDEL (*Compt. rend.*, 1910, 151, 760—762*).—A description of the detection and isolation of a new polysaccharide occurring in the roots of *Verbascum thapsus*. The sugar, for which the name *verbascose* is suggested, crystallises in minute, spherular aggregates of slender needles, m. p. 219—220°, on the Maquenne block; $[\alpha]_D + 169.9^\circ$. It appears to be analogous to stachyose, since, on hydrolysis, dextrose, levulose, and galactose are produced. Verbascose does not reduce Fehling's solution; on oxidation with nitric acid, it yields mucic acid.

Verbascum thapsus appears also to contain a glucoside, hydrolysable by emulsin. W. O. W.

Purification of Starch. GIOVANNI MALFITANO and MILE A. N. MOSCHKOFF (*Compt. rend.*, 1910, 151, 817—819. Compare this vol. i, 301).—Further experimental details are given for the preparation of starch free from electrolytes by the method previously described. Potato starch is the variety most amenable to this method of purification. The material so obtained contains less than 0.02% of ash. With hot water it gives a colloidal solution less viscous than an ordinary starch solution, but from which the substance is precipitated by dilution. W. O. W.

The Adsorption of Acids by Carbohydrates. FRED. ROBINSON (*Proc. Camb. Phil. Soc.*, 1910, 15, 548—558. Compare Fenton and Gostling, *Trans.*, 1898, 73, 554).—The dry carbohydrate is covered with chloroform or carbon tetrachloride, a standard solution of dry hydrogen chloride or bromide in the same solvent is then added, and, after several hours, a known volume is withdrawn, shaken with water, and titrated with barium hydroxide.

Carbohydrates adsorb the acids rapidly, the results agreeing well with an exponential adsorption formula, but the relative order of adsorption is not related to the chemical nature of the carbohydrate. It is also independent of chemical action, as the adsorptive power of starch is the greatest, although starch yields the smallest quantity of chloromethylfurfuraldehyde. Lactose and dextrose have the lowest adsorptive power, lactose and maltose differing widely. Levulose and sucrose become pink, and finally black, with hydrogen bromide. C. H. D.

Hydrocellulose. CARL G. SCHWALBE (*Zeitsch. angew. Chem.*, 1910, 23, 2030—2031).—The conclusions of Jentger (this vol. i, 654) are erroneous, as the cellulose used would retain a considerable quantity of

* and *J. Pharm. Chim.*, 1910, [vii], 2, 481—490.

water, so that the acid is diluted with water, and is not in the so called molecular condition.

C. H. D.

Nitrous Esters of Cellulose. PAUL NICOLARDOT and GEORGES CHERTIER (*Compt. rend.*, 1910, 151, 719—722).—Estimation of the nitrogen in nitrated cellulose by the Schläsing method always gives a higher result than when the analysis is effected in the Lunge nitrometer. This appears to be due to the existence of nitrous esters, which undergo immediate decomposition when dissolved in sulphuric acid. Attempts to prepare such compounds by the action of oxides of nitrogen on cotton under various conditions were unsuccessful, oxidation usually taking place. By their action on viscose, however, in presence of acetic acid, a product was obtained containing 3% of nitrogen (Schläsing) or 5% (Lunge). This was freed from nitrates by treatment with acetone, in which the nitrites are insoluble.

The nitrous esters of cellulose are somewhat unstable, grey substances, pulverulent when dry, but gelatinous when wet. They are insoluble in water and organic solvents; alkalis bring about hydrolysis, nitrites being formed. Hydrolysis is slowly effected by water at the ordinary temperature, and in contact with alcohols, decomposition occurs, the corresponding aldehyde or acid being produced. The deterioration of nitrated cotton is probably connected with the presence of these substances.

W. O. W.

Ammonium and Oxonium Perchlorates. Relationship between Constitution and Behaviour towards Water. KARL A. HOFMANN, R. RÖHN, K. HÜBOLD, and A. METZGER (*Ber.*, 1910, 43, 2624—2630. Compare this vol., i, 105, 168, 187, 370).—The solution of perchlorates in water is primarily due to the formation of hydrates; electrolytic dissociation and hydrolysis are secondary phenomena. Quaternary ammonium perchlorates are not so readily soluble in water as the perchlorates derived from primary, secondary, and tertiary amines. Diazonium perchlorates and the perchlorates of the magenta and methylene-blue series are also sparingly soluble.

Oxonium perchlorates of the type $R_3O \cdot HClO_4$ are readily soluble, whereas tertiary perchlorates, $R_3O \cdot ClO_4$, are sparingly soluble.

These phenomena are attributed to subsidiary valencies of the acidic H atom, which can be used up in attaching water to the molecule of the acid or salt.

The following salts are described: *Trimethylammonium perchlorate*, $NHMe_3 \cdot ClO_4$, doubly refracting prisms and pyramids; at 17° , 20 grams dissolve in 100 of water; *trimethylamineoxazils perchlorate*, $NMe_3O \cdot HClO_4$, hygroscopic cubes; *ethylenediamine perchlorate*, $C_2H_5N_2 \cdot 2HClO_4$, compact prisms, soluble in its own weight of water at 17° ; *tetramethylammonium perchlorate*, $NMe_4 \cdot ClO_4$, tetragonal crystals, decomposing above 300° , solubility 0.341 at 12° , 1.008 at 19° , and 1.554 at 25° ; *tetraethylammonium perchlorate*, solubility 2.392 at 17° , decomposes above 300° ; *trimethylethylammonium perchlorate*, long, rectangular prisms, solubility 11.06 at 17° and 11.97 at 20° ; *trimethylbromoethyl perchlorate*, $C_2H_4Br \cdot NMe_3 \cdot ClO_4$, rectangular plates, m.p. about 200° (decomp.), solubility 3.59 at 19° ; *choline perchlorate*, $OH \cdot C_2H_4 \cdot NMe_3 \cdot ClO_4$, glistening, rectangular plates from absolute

alcohol, solubility 0.89 at 20°; *neurine perchlorate*, $C_8H_9 \cdot NMe_3 \cdot ClO_4$, in prisms, solubility 5.764 at 0°, also soluble in 30% hydrogen peroxide; *betaine perchlorate*, $C_2H_3O_2 \cdot NMe_3 \cdot ClO_4$, doubly refractive plates, solubility 17.73 at 19°; *diphenylhydronium perchlorate*, $IPh_2 \cdot ClO_4$, colourless, felted needles, solubility 0.624 at 19.6°. The perchlorates of malachite-green, crystal-violet, and methylene-blue are sparingly soluble that the solubilities can be estimated by the gravimetric method only. The perchlorates of the corresponding neo-bases are much more readily soluble. *Magenta tetraperchlorate*, $H_2N \cdot N_2 \cdot 4HClO_4$, is a dark orange-coloured, crystalline powder, obtained by mixing the monopерchlorate with 60% perchloric acid and ether; it decomposes above 300° and is hydrolysed by water to the monopерchlorate. *p*-Phenylenediamine, *p*-phenylenedimethylamine, acetyl-*p*-phenylenediamine, and *m*-phenylenediamine, all yield sparingly soluble crystalline diazonium perchlorates, that derived from *p*-phenylenediamine being extremely explosive. The diazo-compounds from *o*-phenylenediamine and *o*- and *p*-aminophenol do not yield crystalline perchlorates.

The following alkaloid perchlorates are formed as precipitates when acetic acid solutions of the base are mixed with excess of 20% perchloric acid solution: *Cinchonine perchlorate* (2), prisms; *strychnine perchlorate* (1), long needles, solubility 0.22 at 15°; *brucine perchlorate* 1, rhombic plates, solubility in 2% perchloric acid solution 0.15 at 18°; *morphine perchlorate* (1), glistening needles, solubility in 4% acid 0.44 at 15°; *cocaine perchlorate* (1), long needles, solubility in 8% acid 0.26 at 6°. The numbers refer to the number of molecules of acid combined with one molecule of alkaloid. Quinine, quinidine, kairine, atropine, nicotine, piperidine, piperazine, and solanine are not precipitated by 20% perchloric acid.

Unisaldehyde perchlorate, $2OMe \cdot C_6H_4 \cdot CHO \cdot HClO_4$, crystallises from etheral solution in colourless prisms or plates, which deliquesce in contact with the air. *Chrysoguinone perchlorate*, $C_{18}H_{10}O_2 \cdot HClO_4$, forms dark violet-coloured prisms, decomposing at about 190°. Anthranol, anthraquinone, diphenylene oxide, and phenyl ether do not yield perchlorates, but dibromophenyl ether and dibromodiphenylene ether yield sparingly soluble perchlorates (3 mols. of oxygen compound to 1 of acid) which are hydrolysed by water.

Xanthoxonium perchlorate, $C_{12}H_9O \cdot ClO_4$, prepared from an ethereal solution of xanthihydrol and 70% perchloric acid, forms intensely yellow crystals; these decompose at 235°, and are hydrolysed by water to xanthihydrol and perchloric acid, but are more stable than the crystals

of xanthone perchlorate. The group $X \cdot O \leq$ is thus comparatively stable (compare Baeyer, this vol., i, 763).

J. J. S.

Some Derivatives of Pentamethylenediamine and a New Convenient Synthesis of 2-Methylpyrrolidine from Piperidine. WILHELM VON BRAUN (Ber., 1910, 43, 2864—2879).—2-Methylpyrrolidine, which cannot be obtained from piperidine in the same way that methyldihydroindole is prepared from tetrahydroquinoline, has been synthesised as follows: Benzoylpiperidine is converted by phosphorus

pentachloride into benzoyl- ϵ -chloroamylamine, and this, for practical purposes, is changed by excess of alcoholic sodium iodide into benzoyl- ϵ -iodoamylamine. The latter reacts rapidly with warm alcoholic 33 trimethylamine to form ϵ -benzoylamino-trimethylamylammonium iodide, $\text{NHBz} \cdot [\text{CH}_2]_5 \cdot \text{NMe}_3\text{I}$, m. p. 189° . (The corresponding chloride is an oil which yields a *platinichloride*, m. p. 198° .) The iodide is converted in the usual manner into a solution of the hydroxide, which, after evaporation to dryness, yields by distillation in a vacuum a mixture of benzoyldimethylpentamethylenediamine, $\text{NHBz} \cdot [\text{CH}_2]_5 \cdot \text{NMe}_2$, b. p. $220-225^\circ/10$ mm. (*picrate*, oily; methiodide, m. p. 189° ; see above), and pentenylbenzamide, $\text{CH}_2=\text{CH} \cdot [\text{CH}_2]_3 \cdot \text{NHBz}$, b. p. $195^\circ/13$ mm., which is easily separated, owing to the insolubility of the latter in dilute acids. The solution of the unsaturated compound in concentrated hydrochloric acid, after many hours at 70° , yields on cooling impure benzoyl- δ -chloroamylamine, which is converted by concentrated hydrochloric acid at $150-160^\circ$ into δ -chloroamylamine hydrochloride; this forms a *platinichloride*, m. p. 192° , and is converted into 2-methylpyrrolidine by warming with alkalis. Since the m.p.'s of the *platinichloride* and of the aurichloride, $181-192^\circ$ (decomp.) and 184° respectively, of the 2-methylpyrrolidine thus prepared do not agree with those, $206-207^\circ$ (decomp.) and $158-161^\circ$ respectively, of Tafel and Fenner's 2-methylpyrrolidine, the author's base has been converted by exhaustive methylation into the quaternary methiodide, the *platinichloride* of which, decomp. 255° , blackening at 240° , agrees exactly with the corresponding derivative of Tafel and Fenner's base.

Benzoyldimethylpentamethylenediamine can be readily prepared by heating aqueous dimethylamine (2 mols.) and benzoyl- ϵ -chloroamylamine on the water-bath. By hydrolysis with hydrochloric acid at 150° it yields as *dimethylpentamethylenediamine*, $\text{NMe}_2 \cdot [\text{CH}_2]_5 \cdot \text{NH}_2$, b. p. $181-182^\circ$ (*aurichloride*, m. p. 168°). Benzoyldiethylpentamethylenediamine, $\text{NEt}_2 \cdot [\text{CH}_2]_5 \cdot \text{NHBz}$, b. p. $232-234^\circ/10$ mm., similarly prepared from diethylamine, yields by hydrolysis as *diethylpentamethylenediamine*, h. p. $87-88^\circ/10$ mm. [*platinichloride*, m. p. 215° (decomp.); *picrate*, m. p. 110°]. Benzoyldiisobutylpentamethylenediamine, $\text{NHBz} \cdot [\text{CH}_2]_5 \cdot \text{N}(\text{C}_4\text{H}_9)_2$, b. p. $250^\circ/10$ mm. (decomp.), yields by hydrolysis as *diisobutylpentamethylene-diamine*, b. p. $126-127^\circ/11$ mm. [*platinichloride*, m. p. 212°]. These three *as-dialkylpentamethylene-diamines* are almost odourless, remain unchanged above 200° , are almost unaffected by air, and do not react with nitrous acid. This inactivity is attributed to steric causes, not to a concentration of the basic properties at the tertiary nitrogen atom to such an extent that the primary nitrogen atom no longer exerts basic functions. The latter explanation is rejected because *as-phenylmethylpentamethylene-diamine*, $\text{NH}_2 \cdot [\text{CH}_2]_5 \cdot \text{NPhMe}$, b. p. $180^\circ/16$ mm. (prepared by hydrolysing the benzoyl derivative obtained from methylaniline and benzoyl- ϵ -iodoamylamine), in which the tertiary nitrogen atom probably has a weaker basic function than the primary, reacts with nitrous acid without the evolution of a gas (probably, therefore, a nitroso-group enters the phenyl nucleus), and also because *o- γ -dimethylaminopropylamine*, $\text{NMe}_2 \cdot [\text{CH}_2]_3 \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2$, b. p. $151^\circ/15$ mm. [*picrate*, m. p. $173-174^\circ$; *platinichloride*, m. p. 213° (decomp.)], in which the aromatic amino-

group is certainly weaker than the aliphatic dimethylamino-group, reacts with nitrous acid with evolution of nitrogen, forming a substance which is soluble in alkalis and is therefore probably *o*- γ -dimethylaminopropylphenol. *o*- γ -Dimethylaminopropylaniline is obtained by hydrolysing its benzoyl derivative, which is prepared from *o*- γ -chloropropylbenzanilide and dimethylamine.

*Di- ϵ -benzoylamino*dimethylamyl ammonium iodide,

m. p. 162° , obtained as a by-product in the reaction between dimethylamine and benzoyl ϵ -iodoamylamine, is converted by hydriodic acid at 160° into *di- ϵ -aminodimethylamyl ammonium iodide dihydriodide*, $(\text{HI} \cdot \text{NH}_2 \cdot [\text{CH}_2]_5)_2 \text{NMe}_3 \text{I}$, m. p. 210° ; the corresponding *dihydrochloride*, $(\text{HCl} \cdot \text{NH}_2 \cdot [\text{CH}_2]_5)_2 \text{NMe}_3 \text{Cl}$, has m. p. 240° , and forms a *platinichloride*, m. p. 221° . The dihydriodide by exhaustive methylation yields the *tris-quaternary ammonium iodide*,

which does not melt at 300° ; the corresponding *tris-quaternary chloride* is extremely hygroscopic, and forms a *platinichloride*, m. p. 286° ; blackening at about 250° .

C. S.

Cyclic Imines. IV. Constitution of Hexamethyleneimine and the Action of $\alpha\zeta$ -Diiodohexane on Bases. JULIUS JOSE BRAUN (*Ber.*, 1910, 43, 2853—2864).—The presence of a seven-membered heterocyclic ring in hexamethyleneimine, which is denied by Blaise and Houillon (*Abstr.*, 1906, i, 692), is proved by distilling *hexamethyleneimine*, b. p. 206 — $208^\circ/19$ mm., with phosphorus pentachloride and boiling the portion of the distillate which is insoluble in water with an excess of alcoholic sodium phenoxide for ten hours, whereby $\alpha\zeta$ -diphenoxyhexane is obtained in 65% yield.

The reactions between $\alpha\zeta$ -diiodohexane and methylamine, dimethylamine, aniline, and piperidine do not yield a trace of hexamethyleneimine derivatives, the products being derivatives of $\alpha\zeta$ -diaminohexane and of α -pipercoline, and substances of high molecular weight. Thus $\alpha\zeta$ -diiodohexane and aqueous methylamine (4 mols.) in the presence of a little alcohol, after two days at the ordinary temperature, yield 6% of 1-methyl-2-pipercoline (identified in the form of the methiodide, m. p. 255°) and the platinichloride, decomp. 222° , obtained therefrom), 3% of dimethyl- $\alpha\zeta$ -diaminohexane (*dibenzenesulphonyl* derivative, m. p. 182° ; *picrate*, m. p. 137°), and about 70% of a mixture of substances of high molecular weight. When heated on the water-bath for many hours, $\alpha\zeta$ -diiodohexane and aniline (3 to 4 mols.) yield, *o*-phenylhexamethyleneimine or phenyl- α -pipercoline, but about 50% of *di*phenyl- $\alpha\zeta$ -diaminohexane, $\text{NHPh} \cdot [\text{CH}_2]_6 \cdot \text{NHPh}$, m. p. 74° , which forms a *picrate*, m. p. 172° , a *dibenzoyl* derivative, m. p. 163° , and a *diazotro*-compound, m. p. 69° . $\alpha\zeta$ -Diiodohexane and dimethylamine yield dimethyl-2-pipercolinium iodide and *tetramethyl- $\alpha\zeta$ -diaminohexane*, $\text{NMe}_3 \cdot [\text{CH}_2]_6 \cdot \text{NMe}_3$, b. p. $103^\circ/20$ mm., which forms a *picrate*, m. p. 162° , and a *methiodide*, which does not melt at 270° . $\alpha\zeta$ -Diiodohexane and piperidine in alcoholic solution on the water-bath yield about 50% of $\alpha\zeta$ -di-1-piperidylhexane,

h. p. 198°/16 mm. (*picrate*, m. p. 208°, blackening at 195°; *platini chloride*, m. p. 230°; *methiodide*, m. p. 240°), together with a quaternary iodide, $\text{CH}_2\langle\text{CH}_2\text{---CH}_2\rangle\text{NI}\langle\text{CHMeCH}_2\rangle\text{CH}_2$, m. p. 263°, which is identical with the product obtained from 2-pipecolide and α -di-iodopentane.

The preceding behaviour of di-iodohexane with primary and secondary bases proves that caution is necessary in assigning cyclic structures to substances produced in reactions in which the reagents employed would, apparently obviously, produce ring compounds.

C. S.

Detection of Choline. Trimethylamine. MAX KAUFFMANN and DANIEL VORLÄNNER (*Ber.*, 1910, 43, 2735—2743).—Choline platini chloride is dimorphous; it separates from water in monoclinic anhydrous crystals, and from dilute alcohol in regular octahedra and cubes or combinations of these. The monoclinic salt is slightly deeper orange in colour; both have m. p. 215—240° with frothing. The monoclinic salt is doubly refractive. The conversion of one form into the other takes place on crystallisation from water or 50% alcohol respectively, and affords a certain test for the presence of choline. Choline may also be detected by distillation with potassium hydroxide, when trimethylamine is formed and recognised by its odour. When trimethylamine is smelt for any length of time, the odour becomes firstly like that of a monoamine, and subsequently like that of ammonia which persists. Many other substances show a similar "reversal of odour."

When choline chloride is heated with excess of benzenesulphonyl chloride, trimethylchloroethylammonium chloride, $\text{NMe}_3(\text{C}_2\text{H}_4\text{Cl})\text{Cl}$, is formed. The platini chloride crystallises in octahedra, m. p. 251°; the *aurichloride* forms slender, yellow, doubly-refractive needles. This chloroethyl base takes a middle position between neurine and choline in its toxic qualities.

By the interaction of aqueous trimethylamine and benzenesulphonyl chloride, a quaternary ammonium salt is obtained. The *platini chloride*, $(\text{SO}_2\text{Ph}\cdot\text{NMe}_3)_2\text{PtCl}_6\cdot 4\text{H}_2\text{O}$ (?), crystallises in anisotropic, prismatic, or tabular forms, m. p. 209—223°. The *aurichloride* separates in microscopic, doubly-refractive needles, m. p. 196°, decomp. 246°. The *chloride* was obtained in needles; it gives a yellow precipitate with picric acid.

E. F. A.

Derivatives of Amino-alcohols. ERNEST FOURNEAU (*J. Pharm. Chim.*, 1910, [vii], 2, 337—344, 397—401. Compare this vol., i, 246).—The first paper deals with the esterification of these alcohols, and shows (1) that the salts of such esters are easily crystallisable, and are convenient for the identification of the alcohols; (2) that they are readily obtained by mixing solutions in benzene of the amino-alcohols and the necessary acid chloride or bromide, and (3) that this method of formation appears to be analogous with Einhorn's method of using pyridine to promote esterification of alcohols, an additive product of the type $\text{CH}_2\text{R}\cdot\text{N}(\text{CO}\cdot\text{R})\text{R}_2\text{Cl}$ being formed in both cases, which on

warming yields the ester. Mairé's observation that amino-alcohols containing two ethyl groups attached to the nitrogen atom behave abnormally, is confirmed (Abstr., 1908, i, 248), but an ester was obtained in this case by avoiding the use of any solvent. Such amino-alcohols, however, behave normally with cinnamoyl chloride. The esters of the amino-alcohols are liquid, distil without decomposition, are stable towards alkalis, are easily hydrolysed by mineral acids, and are much less basic than the amino-alcohols; they have little or no colour. Their halogen acid salts crystallise well as a rule, but may be hygroscopic. The second paper describes a series of amides obtained by the application of the Schotten-Baumann reaction to the amino-alcohols. In these conditions no esterification of the hydroxyl group occurs.

Dimethylaminotrimethylcarbinol hydrochloride furnishes a *benzoate*, m. p. 202° , crystallising with 1 mol. of alcohol, a *cinnamate*, m. p. 208° , and an *isovalerate*, m. p. 125° . Dimethylaminodimethylethylcarbinol gives a *benzoate*, b. p. $150^{\circ}/13$ mm., a *diethylcarbamate*,

b. p. $136^{\circ}/41$ mm. [the *hydrochloride* of which, m. p. 142° (decomp.), crystallises from acetone in hygroscopic needles, and yields an *aurichloride*, m. p. 98° , which forms orange-red needles, whilst the *hydrobromide*, m. p. 148° , is very soluble in alcohol and exhibits a marked sedative action], a *valerate*, b. p. $128^{\circ}/23$ mm. (yielding a *hydrochloride*, m. p. 151° , and a *hydrobromide*, m. p. 126° , both of which are anaesthetics), a *bromovalerate hydrochloride*, m. p. 158° , which is markedly anaesthetic, a *diethylacetate hydrobromide*, m. p. 169° , a *bromodiethylacetate hydrochloride*, m. p. 160° , a *hexoate*, b. p. 152° (under reduced pressure), a *bromohexoate hydrochloride*, m. p. 130° , a *bromooheptoate hydrochloride*, m. p. 128° (which is markedly anaesthetic), and a *bromolaurate hydrochloride*, m. p. 99° . The higher homologues beyond the hexoate show increasingly the characters of the acid group, and exhibit the properties of soaps. The *hydrochlorides* of the *benzoyl* derivatives of the following amino-alcohols: dimethylaminomethyldiethylcarbinol, dimethylaminodimethylpropylcarbinol, diethylaminodimethylethylcarbinol, and dimethylaminodimethylisocamylcarbinol melt at 180° , 146° , 140° , and 142° respectively. The last of these gives a *platinichloride*, m. p. 178° , and the amino-alcohol also furnishes a *cinnamate hydrochloride*, m. p. 110° .

Aminodimethylethylcarbinol gives with bromovaleryl chloride an *amide*, $\text{CHMe}_2\text{CHBr}\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CMeEt}\cdot\text{OH}$, m. p. 93° , forming brilliant octahedral crystals. Valeryl chloride yields with the same amino-alcohol an *amide*, m. p. $50-60^{\circ}$, b. p. $190^{\circ}/32$ mm., and with methylaminodimethylethylcarbinol and iminobisdimethylethylcarbinol, *amides*, having b. p. $163^{\circ}/25$ mm. and $210^{\circ}/23$ mm. respectively; the second substance crystallises in spangles, and has m. p. $152-153^{\circ}$. All these amides are sedative, and some of them hypnotic; they are less toxic than the corresponding esters described in the first paper.

Ethyl chlorocarbonate reacts in presence of sodium hydrogen carbonate with aminodimethylethylcarbinol to form the *urethane*, $\text{OH}\cdot\text{CMeEt}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CO}_2\text{Et}$, b. p. $151-152^{\circ}/17$ mm., whilst with

the same alcohol propyl chlorocarbonate furnishes the *propyl* ester, having b. p. 174—175°. These urethanes are hypnotic in action, but must be given in large doses, for example, 0.4 gram per kilo. of body weight in rabbits. They are toxic to rabbits in doses of 1.8 grams per kilo.

Aminodimethylethylcarbinol with potassium isocyanate yields the substituted *carbamide*, $\text{OH} \cdot \text{CMeEt} \cdot \text{CH}_2 \cdot \text{NH} \cdot \text{CO} \cdot \text{NH}_2$, m. p. 156°, which is a powerful hypnotic; the corresponding *methylcarbamide*, similarly obtained, has m. p. 128°, and *carbamide bisdimethylethylcarbinol*, m. p. 96° (approx.).

T. A. H.

Carnitine; Synthesis of γ -Trimethylamino- β -hydroxybutyric Acid. R. ENGELAND (*Ber.*, 1910, 43, 2705—2707).—Carnitine, present in meat extract, has been pronounced to be γ -trimethylamino- α -hydroxybutyric acid (Engeland, *Abstr.*, 1909, i, 557). It is shown now to differ from γ -trimethylamino- β -hydroxybutyric acid, which is obtained synthetically by heating epichlorohydrin with anhydrous hydrogen cyanide to form chlorohydroxybutyronitrile; this, when heated with alcoholic trimethylamine in sealed tubes at 110°, or even in open vessels at 70—80°, is converted into the *chloride* of γ -trimethylamino- β -hydroxybutyronitrile. The *aurichloride* of this compound crystallises in reddish-yellow prisms, m. p. 124—125°. Hydrolysis of the nitrile requires ten hours' boiling with a mixture of aqueous and alcoholic hydrochloric acid. A by-product is a bimolecular anhydride-like product, of which the sparingly soluble *aurichloride*, $\text{C}_{14}\text{H}_{20}\text{O}_5\text{N}_3 \cdot 2\text{AuCl}_4$, was analysed. The *aurichloride* of γ -trimethylamino- β -hydroxybutyric acid crystallises in reddish-yellow plates, m. p. 145°, decomp. at 225°. The *chloride* crystallises in needles, sparingly soluble in alcohol. When heated with alcohol containing hydrogen chloride, it is converted quantitatively into the *ethyl* ester, the *platinichloride* of which sinters at 200°, m. p. 210—212°. These derivatives are very different from those of carnitine.

R. F. A.

Syntheses of Hydroxybetaines. II. Synthesis of γ -Trimethyl- β -hydroxybutyrobetaine (*dl*-isoCarnitine). ADOLF ROLLETT (*Zeitsch. physiol. Chem.*, 1910, 69, 60—65. Compare this vol., i, 658).—*Ethyl γ -trimethylamino- β -hydroxybutyrate chloride*, $\text{NMe}_3\text{Cl} \cdot \text{CH}_2 \cdot \text{CH}(\text{OH}) \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$, is formed when Lespieau's ethyl γ -chloro- β -hydroxybutyrate (*Abstr.*, 1899, i, 243, 790) is heated with an alcoholic solution of trimethylamine for six hours at 100°. The *platinichloride*, $\text{C}_{14}\text{H}_{20}\text{O}_5\text{N}_3\text{PtCl}_6$, crystallises from 90% alcohol in slender, pale yellow needles, which decompose at 233—234°. The *platinichloride* of the corresponding acid,

forms orange-coloured crystals, decomposing at 248°, and is isomeric with carnitine platinichloride (m. p. 214—218°).

A by-product obtained in the preparation of the ester is trimethyl-ethylammonium chloride, which is deposited as the *platinichloride*, $(\text{NMe}_3\text{Et})_2\text{PtCl}_6$, in the form of pale orange-coloured plates decomposing at 281—284°. The corresponding *aurichloride*, $\text{NMe}_3\text{EtCl}_4\text{AuCl}_4$, forms characteristic needles, which are unchanged at 290°. J. J. S.

Action of Ammonia on Unsaturated Acids. II. GEORGE I. STADNIKOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 885—890. Compare Abstr., 1909, i, 772).—In order to confirm the explanation already given for the formation of imino-acids by the action of aqueous ammonia on unsaturated acids, a mixture of crotonic and aminoacetic acids was heated in a sealed tube at 120—130° with sufficient aqueous ammonia to convert both acids into their ammonium salts. The products of the reaction were ethyl β -aminobutyrate and diethyl- β -iminobutyrateacetate, $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CHMe}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$, b. p. 144° 19 mm., D_4^{20} 1.0340, n_D^{20} 1.4370, a colourless, mobile liquid, soluble in alcohol and ether, and readily saponified into β -iminoacetic-butyric acid, $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CHMe}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, m. p. 200° (decomp.). To avoid the formation of β -amino-acid, and thus make this a convenient general method for the preparation of imino-acids, the ammonium salts are substituted by the potassium salts of the amino- and unsaturated acids. To prove that glycine unites with crotonic acid in the β -position, propaldehyde and potassium cyanide were made to react with the hydrochloride of ethyl aminoacetate, when α -iminoacetic-butyric acid, $\text{CO}_2\text{H}\cdot\text{CHEt}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, H_2O , was formed. It forms large, elongated prisms, m. p. 104—105°. The hydrochloride forms small crystals, decomposing at 175—177°. Thus, in the interaction of α -amino-acids with crotonic acid, $\alpha\beta$ -imino-dialiphatic acids are formed. Z. K.

Synthesis of γ -Guanidinobutyric Acid. R. ENGELAND and FR. KUTSCHER (*Ber.*, 1910, 43, 2882—2883).—This substance may be readily prepared by the following method. Concentrated solutions of cyanamide and of twice its weight of γ -aminobutyric acid are mixed, rendered alkaline with a few drops of ammonia, and kept for five weeks at the ordinary temperature, the evaporated ammonia being replaced from time to time. The guanidinobutyric acid which crystallises out is purified by conversion into the hydrochloride, which is sparingly soluble in concentrated hydrochloric acid and in alcohol. The aurichloride, $\text{C}_5\text{H}_{12}\text{O}_2\text{N}_2\text{AuCl}_4$, forms broad, lustrous plates, m. p. 198—200°. The hydrochloride regenerated from it has m. p. 184°; it is precipitated by phosphotungstic acid even from dilute solutions, but not by picric acid or sodium picrate. The synthetic acid is identical with that obtained by oxidation of arginine or agmatine.

R. V. S.

Action of Some Salts of Tervalent Metals on Thiocyanates. CORRADO BONGIOVANNI (*Boll. chim. farm.*, 1910, 49, 789—791. Compare Abstr., 1908, i, 859).—Molybdenum thiocyanate is decolorised by the same substances which decolorise ferric thiocyanate. Chromic hydroxide and thiocyanic acid yield a reddish-violet solution, which is much less intensely coloured than that of ferric thiocyanate, and it behaves differently in other respects, for it is not hydrolysed appreciably, and is not decolorised by saline solutions, oxalic acid, or acetic acid. Vanadium thiocyanate behaves similarly to the ferric compound. The mode of formation and the properties of these substances do not accord with Tarugi's hypothesis (*loc. cit.*) as to their constitution.

R. V. S.

Orientation in the Benzene Nucleus. JULIUS OBERMILLER (*J. pr. Chem.*, 1910, [ii], 82, 462—472).—A reply to, and a claim for priority over, Holleman.

C. S.

Unsaturated Hydroaromatic Hydrocarbons with Semicyclic Double Linkings. KARL AUWERS and G. PETERS (*Ber.*, 1910, 43, 3076—3094).—In two papers published already (this vol., ii, 365, 367), Auwers and Eisenlühr discuss the determination of constitution by optical methods, and point out the importance of ascertaining the normal value of the exaltation of refractivity and dispersivity in undisturbed conjugated systems and the influence thereon of various kinds of distortion. In pursuance of this object they are attempting to prepare and examine optically, substances derived from the three systems

and the present paper gives the results of attempts to solve this question for the third of these

1:3-Dimethyl- Δ^3 -cyclohexen-5-one on treatment with magnesium methyl iodide furnishes 1:3:5-trimethyl- Δ^3 -cyclohexen-5-ol, m. p. 46°, b. p. 87—90°/17 mm., D_4^{20} 0.9132 to 0.9140, n_D^{20} 1.47349, $n_D^{19.3}$ 1.47053, and $n_D^{18.3}$ 1.48715 (whence $\Sigma_s = +0.36$, $\Sigma_D = +0.34$, and $\Sigma_v - \Sigma_s = 9\%$); it is crystalline. On heating alone or with dehydrating agents, it yields a hydrocarbon having b. p. 63—64°/17 mm. or 151°/760 mm., D_4^{20} 0.821 to 0.828, n_D^{20} 1.467 to 1.477, n_D^{19} 1.471 to 1.481 (whence $\Sigma_s = +0.68$ to $+1.02$, and $\Sigma_v - \Sigma_s$ varies from 24 to 40%). These data agree with the assumption that the hydrocarbon is

1:3-dimethyl-5-methylene- Δ^3 -cyclohexene, $\text{CH}_2 \begin{smallmatrix} \text{CMe} \\ \text{CHMe} \end{smallmatrix} \text{CH} \text{C}(\text{CH}_3)_2$

and belongs to the third system referred to above. On oxidation with permanganate, it furnishes a saturated neutral substance, $\text{C}_8\text{H}_{14}\text{O}$, m. p. 96—97°, but on treatment with ozone in acetic acid it yields γ -acetyl- β -methylbutyric acid (Knocvenagel and Brunswick, *Abstr.*, 1902, i, 640), identical with that obtained by the action of permanganate or ozone on 1:3-dimethyl- Δ^3 -cyclohexen-5-one, which is probably formed as an intermediate product in the oxidation of the hydrocarbon. γ -Acetyl- β -methylbutyric acid bas b. p. 140—142°/12 mm., D_4^{17} 1.0614, $n_D^{17.2}$ 1.44383, $n_D^{16.2}$ 1.44611, and yields a crystalline semicarbazone, m. p. 170—171°. The hydrocarbon on bromination and subsequent treatment with potassium hydroxide in alcohol yields mesitylene.

1:3-Dimethyl-5-ethylidene- Δ^3 -cyclohexene, b. p. 178°, D_4^{20} 0.833 to 0.837, n_D^{20} 1.476 to 1.483, n_D^{19} 1.480 to 1.487 (whence $\Sigma_s = +0.80$ to $+1.05$, $\Sigma_D = +0.84$ to $+1.10$, and $\Sigma_v - \Sigma_s = +27$ to 40%), probably identical with Klages' dihydroethylxylene (*Abstr.*, 1907, i, 597), is obtained by heating the corresponding tertiary alcohol alone or with oxalic acid.

1:3-Dimethyl-5-isopropylidene- Δ^3 -cyclohexene, similarly prepared, has b. p. 101°/36 mm. or 196°/760 mm., D_4^{20} 0.841 to 0.848, n_D^{20} 1.481 to 1.492, n_D^{19} 1.485 to 1.496 (whence $\Sigma_s = +0.70$ to $+1.20$, $\Sigma_D = +0.73$ to $+1.26$, and $\Sigma_v - \Sigma_s = 33$ to 51%). These hydrocarbons agree in general properties with the similar products containing semicyclic double linkings described by Wallach (*Abstr.*, 1907, i, 425), but possibly all of them contained isomerides having two endocyclic double linkings.

Pure hydrocarbons of this type probably have $\Sigma_e = +1.0$ to 1.2 , $\Sigma_D = +1.1$ to 1.3 , and $\Sigma_\gamma - \Sigma_a = 40$ to 50% . T. A. H.

Reducibility of Conjugated Double Linkings in Hydroaromatic Substances. KARL AUWERS and G. PETERS (*Ber.*, 1910, 43, 3111—3120).—An extension of the work described in the preceding abstract and this vol., i, 841. The results resemble those obtained by Klages (*Abstr.*, 1904, i, 45, 1001) in the case of styrene derivatives, and show that the reducibility of the hydroaromatic hydrocarbons depends on the number, nature, and distribution of the side-chains attached to the carbon atoms in the double linkings of the conjugated system. This influence has been illustrated already by the reduction of 3-chloroisoterpinolene to a mixture of menthenes (this vol., i, 122), by Semmler's reduction of chlorocarvenene to the corresponding hexadiene under similar conditions, and by the non-reducibility of hydrocarbons of this type, described by Rupe and Emmerich (*Abstr.*, 1908, i, 556).

5-Chloro-1:3-dimethyl- $\Delta^{3,5}$ -cyclohexadiene, already prepared by Klages and Knoevenagel (*Abstr.*, 1895, i, 654), has b. p. $68-70^\circ/17$ mm., $D_4^{25} 1.0065$, $n_D^{25} 1.50022$, $n_D^{20} 1.50459$ (whence $\Sigma_D = +0.69$), but the sample was probably not quite pure. On careful reduction with sodium in wet ether it yielded 1:3-dimethyl- $\Delta^{3,5}$ -cyclohexadiene, b. p. $128-129^\circ/760$ mm., $D_4^{25} 0.821$, $n_D^{25} 1.467$, $n_D^{20} 1.471$ (whence $\Sigma_e = +0.62$, $\Sigma_D = +0.68$, and $\Sigma_\gamma - \Sigma_a = 26\%$), which furnished a *dihydrochloride*, b. p. $93-97^\circ/16$ mm., and is possibly identical with the *dihydro-m-xylene* described by Harries and Antoni (*Abstr.*, 1903, i, 614), the difference in physical constants being perhaps due to impurity in both specimens. On further reduction in ether or, better, in alcohol, the chlorodimethylcyclohexadiene furnishes 1:3-dimethyl- Δ^1 -cyclohexene, b. p. $126-127^\circ/760$ mm., $D_4^{25} 0.806$, $n_D^{25} 1.447$, $n_D^{20} 1.450$ (whence $\Sigma_e = +0.26$, $\Sigma_D = +0.24$, and $\Sigma_\gamma - \Sigma_a = +9\%$) (compare Knoevenagel, *Abstr.*, 1897, i, 606), which yields a *mono-hydrochloride*. T. A. H.

Derivatives of 1:3-Dichloro-4-iodobenzene with a Multi-valent Iodine Atom. CONRAD WILLGERONT and MATTHIAS BOLLERT (*Ber.*, 1910, 43, 2641—2646).—2:4-Dichloroaniline is best prepared by the action of concentrated hydrochloric acid and potassium chlorate on acetanilide and subsequent hydrolysis of the acetyl derivative by boiling with hydrochloric acid. A small amount of *s*-trichloroaniline is formed at the same time, but this is readily removed, as it is insoluble in hydrochloric acid. The dichloroaniline can be transformed into the corresponding 1:3-dichloro-4-iodobenzene, $C_6H_3Cl_2I$, by the Sandmeyer reaction. The iodo-derivative has b. p. 257° (corr.), and yields a *dichloride*, $C_6H_3Cl_2 \cdot ICl_2$, in the form of pale yellow needles, which decompose at 107° . 1:3-Dichloro-4-iodosobenzene, $C_6H_3Cl_2 \cdot IO$, is a yellow-coloured powder with the characteristic iodoso-odour, and decomposes at about 196° . It does not yield stable salts. The *chromate* forms a red powder. *Di-m-dichlorophenyl-iodonium hydroxide*, $(C_6H_3Cl_2)_2I \cdot OH$, yields a faintly alkaline aqueous solution; the *iodide*, $(C_6H_3Cl_2)_2I \cdot I$, forms a yellow, crystalline precipitate, which decomposes at 135° ; the *bromide* decomposes at 159° ; the *chloride*, $(C_6H_3Cl_2)_2I \cdot Cl$,

is more readily soluble, and decomposes at 185° ; the *platinichloride*, $C_{24}H_{12}Cl_{14}I_2Pt$, forms red needles, decomposing at 166° ; the *mercurichloride*, $C_{12}H_6Cl_2IHg$, crystallises from alcohol in needles, m. p. 164° (decomp.), and the *dichromate*, $C_{24}H_{12}O_7Cl_3I_2Cr_2$, forms an orange-coloured precipitate, which is very unstable and explodes at 151° .

o-Tolyl-1:3-dichlorophenyliodonium iodide, $C_6H_4Me \cdot I(C_6H_3Cl_2)_2$, prepared by Meyer and Hartmann's method (Abstr., 1894, i, 242) by shaking equivalent quantities of *o*-iodotoluene and 1:3-dichloro-4-iodobenzene with freshly precipitated silver oxide and water and reducing with sulphur dioxide, is yellow, and has m. p. 127° . The *hydroxide* is soluble in water, yielding a faintly alkaline solution; the *chloride*, $C_{13}H_{10}Cl_3I$, is colourless, and has m. p. 203° ; the *bromide*, $C_{13}H_{10}Cl_2BrI$, crystallises from ether in plates, sinters at 170° , and decomposes at 185° ; the *nitrate*, $C_{13}H_{10}O_3NCl_3I$, has m. p. 183° (decomp.); the *dichromate*, $C_{26}H_{20}O_7Cl_3I_2Cr_2$, is yellow, and decomposes at 141° ; the *mercurichloride*, $C_{13}H_{10}Cl_2IHg$, forms colourless needles, m. p. 163° .

Phenyl-1:3-dichlorophenyliodonium iodide, $C_6H_5Cl_2 \cdot IPh \cdot I$, is yellow, but turns red on exposure to the air, and has m. p. 133° ; the *chloride*, $C_{12}H_9Cl_3I$, crystallises in colourless needles, m. p. 203° ; the *bromide* crystallises from alcohol in plates, m. p. 196° ; the *platinichloride*, $C_{24}H_{16}Cl_{10}I_2Pt$, forms yellow needles, m. p. 156° (decomp.), and the *dichromate*, $C_{22}H_{16}O_7Cl_3I_2Cr_2$, has m. p. 146° (decomp.).

1:3-Dichlorophenyl-1:3-dichloro-4-iodophenyliodonium chloride, $C_6H_3Cl_2 \cdot I(C_6H_3Cl_2)_2Cl$, crystallises from alcohol, and has m. p. 160° ; the *bromide* crystallises in colourless needles, m. p. $131-132^{\circ}$; the *iodide*, $C_{12}H_9Cl_3I_2$, has m. p. 103° ; the *dichromate*, $C_{22}H_{16}O_7Cl_3I_2Cr_2$, decomposes at 173° , and the *platinichloride*, $C_{24}H_{16}Cl_{10}I_2Pt$, forms a sparingly soluble, orange-coloured precipitate, m. p. 156° , after softening at 145° .
J. J. S.

Limits of Activity of Chloromonoiodobenzenes with Regard to the Formation of Compounds with Multivalent Iodine. CONRAD WILLGERODT and KARL WILCKE (*Ber.*, 1910, 43, 2746-2756). —*s*-Trichlorophenyl iododichloride, $C_6H_3Cl_3 \cdot ICl_2$, crystallises in large, compact, sulphur-coloured leaflets, decomp. 100° .

s-Trichloroiodosobenzene is a slightly yellow, amorphous substance, which softens at 91° , decomp. 106° . The *basic sulphate*,

prepared by pouring 10% sulphuric acid on the iodoso-compound, is a colourless, crystalline powder, decomp. 168° . The *basic nitrate* is a bright yellow, crystalline mass, decomp. 143.4° , with evolution of red fumes. The *acetate* is obtained in colourless prisms grouped in rosettes, m. p. 166.8° .

s-Trichloroiodoxybenzene could not be obtained from the iodoso-compound.

Phenyl-s-trichlorophenyliodonium chloride, $C_6H_5Cl_2 \cdot IPhCl$, is a yellow powder, m. p. $118-119^{\circ}$. The corresponding *iodide* begins to fuse at 90° , is melted clear at $140-150^{\circ}$, decomp. above 200° .

as *Trichlorophenyl iododichloride* crystallises in small, sulphur coloured needles, decomp. 90° .

as *Trichloriodosobenzene* softens at 168° , decomp. 184° .

as *Trichloriodoxybenzene*, $C_6H_2Cl_3 \cdot IO_2$, prepared by oxidation of the iodide chloride with sodium hypochlorite, forms needles, decomp. 240° without explosion.

as *Tetrachloroaniline* has m. p. 89° . as *Tetrachloriodobenzene* does not form an iododichloride, and parts with iodine when chlorinated. *Pentachloroaniline* has m. p. 232° . On diazotisation and addition of potassium iodide, *pentachloriodobenzene* is obtained in colourless crystals, m. p. 208.5° ; it does not give an iododichloride.

It would seem that no iodoxy-compound is formed when iodine is situated between two halogen atoms; apparently these exercise a neutralising influence on the valency of the iodine atom, and prevent the attachment of the second oxygen atom.

E. F. A.

Action of Nitric Acid on Saturated Hydrocarbons. IV.
S. S. NAMEKIN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 581—585. Compare Abstr., 1909, i, 372).—When saturated hydrocarbons are nitrated with nitric acid, it is found that with the diminution of the relative quantity of the latter, the nitration products increase, whilst the oxidation processes decrease. Now, aluminium nitrate, $Al(NO_3)_3 \cdot 9H_2O$, melts at 73° , and decomposes completely into aluminium hydroxide and nitric acid at 140° , and between these two temperatures there is a certain equilibrium between the salt and its decomposition products. If, therefore, this salt is used for nitration, within these temperature limits the nitric acid will be used up as formed, and the equilibrium will thus be constantly disturbed. The acid will thus always be present in a relatively small quantity; the yield of nitration products should, therefore, be better than if an equivalent quantity of free nitric acid were employed. Experiments with *cyclohexane* at $115-120^{\circ}$ completely confirmed these considerations, a yield of 56.7% of mononitro-product being obtained; free nitric acid has never given such a high yield. *cycloHexanone*, possibly its nitro-derivative, $C_6H_{11}O_2N$, and *dinitrodicyclohexane*, $C_{12}H_{20}O_2N_2$, m. p. $216.5-217^{\circ}$ (corr.) were formed as by-products. The latter, crystallising in small needles, was also obtained synthetically.

Z. K.

cycloHexyl-ψ-nitrole. S. S. NAMEKIN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 585—586).—When a few pieces of ice and then dilute sulphuric acid are added to a mixture of an alkaline solution of nitro-*cyclohexane* and sodium nitrite, a blue oil at once separates, and collects at the bottom of the vessel. After some time, the oil is gradually converted into colourless crystals, which rise to the top of the liquid. These two substances are regarded as two modifications of the *ψ-nitrole*, the blue liquid being unimolecular, the solid, bimolecular.

Solid *cyclohexyl-ψ-nitrole*, $C_6H_{11}O_2N_2$, m. p. $70-71^{\circ}$ (decomp.), gives a blue solution in chloroform, and is oxidised by chromic acid in acetic acid solution, forming 1:1-*dinitrocyclohexane*, b. p. $142-143^{\circ}/35$ mm., D_4^{20} 1.2452, n_D^{20} 1.4732, a heavy, yellow oil with a fairly pleasant odour.

Z. K.

Action of Nitric Acid on Methylcyclohexane. S. S. NAMETSKIN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 691—701).—When methylcyclohexane is nitrated with nitric acid (D 1.2) or aluminium nitrate in a sealed tube, the chief product is the 1-nitro-derivative, the 3- and 4-nitro-derivatives also being obtained, more of the former when nitric acid is employed, and more of the latter with aluminium nitrate.

1-Nitro-1-methylcyclohexane, $C_7H_{13}O_2N$, b. p. 109—110°/40 mm., D_4^{20} 1.0547, D_4^{25} 1.0384, n_D^{20} 1.4580, is a colourless liquid with a pleasant odour; when heated with nitric acid, it is partly oxidised to succinic and oxalic acids, and with tin and hydrochloric acid it yields 1-amino-1-methylcyclohexane.

3-Nitro-1-methylcyclohexane, mixed with a very small quantity of the 1-nitro-derivative, has b. p. 119—120°/40 mm., D_4^{20} 1.0547, D_4^{25} 1.0382, n_D^{20} 1.4618, yields on reduction 3-amino-1-methylcyclohexane, b. p. 152—153°/752 mm., D_4^{20} 0.8562, n_D^{20} 1.4558, which is optically inactive, and gives a benzoyl derivative, m. p. 95—97°. As a by-product in the formation of the amine, 1-methylcyclohexan-2-one, $C_7H_{12}O$, is obtained; the latter compound is also formed by the oxidation of an alkaline solution of the nitro-compound with potassium permanganate, or by the action of sulphuric acid on the potassium nitro-compound. It has b. p. 163—169° (corr.), D_4^{20} 0.9179, n_D^{20} 1.4453, and yields two semicarbazones, m. p. 172—180° and 167—169°. When oxidised with permanganate, the nitro-compound yields α - and β -methyladipic acids.

Nitrocyclohexane, b. p. 123—124°/40 mm., D_4^{20} 1.0459, n_D^{20} 1.4684, seems identical with the substance obtained by Zelinsky (*Abstr.*, 1908, i, 864). When oxidised, it yields adipic acid. Besides nitro-compounds, nitric acid, when acting on methylcyclohexane, yields a number of oxidation products, namely, adipic, succinic, oxalic, glutaric, and pyrotartaric acids. The nature of the oxidation processes is discussed.

The nitro-compound from naphtha methylcyclohexane could not be obtained pure. The impure product has b. p. 109—110°/40 mm., D_4^{20} 1.0234, D_4^{25} 1.0430, n_D^{20} 1.4553. With tin and hydrochloric acid it gave an amine, b. p. 143—145°/755 mm., D_4^{20} 0.8632, D_4^{25} 0.8493, n_D^{20} 1.4509, the benzoyl derivative, $C_7H_{13} \cdot NH \cdot COPh$, of which has m. p. 99—100°. Z. K.

Reduction of Nitro-derivatives by Spongy Copper. ALPHONSE MAILHE and MARCEL MURAT (*Bull. Soc. chim.*, 1910, [iv], 7, 952—956).—Bougault has observed (*Abstr.*, 1909, ii, 310; compare Bach, this vol., ii, 31) that sodium hypophosphite added to copper sulphate solution furnishes a precipitate of spongy copper, which, in presence of sodium hypophosphite, decomposes water, liberating hydrogen. This process has been applied to the reduction of nitro-derivatives dissolved in alcohol, and gives good yields, complete in some cases, of the corresponding amines. The presence of halogen atoms or hydroxy-groups in the nitro-derivatives does not impede the reaction, and the halogen or hydroxy-group remains unattacked in the aromatic nucleus. The reaction is likely to be useful in the manu-

facture of aminophenols. Reduction is not effected when hydrogen under pressure is applied to a suspension of spongy copper in a solution of a reducible substance.

The substance to be reduced is dissolved in alcohol and placed in a flask with spongy copper. The flask is provided with a stopper carrying a reflux apparatus, and a bromine tube holding a supply of sodium hypophosphite solution, which is added from time to time as the action slackens. The nitro-derivatives tried include the following: nitroethane, *o*- and *p*-nitrotoluene, *o*-chloronitrobenzene, *p*-bromonitrobenzene, nitronaphthalene, *o*-nitrophenol, and 2:3-dinitrophenol.

T. A. H.

Spontaneous Decomposition of Phenylnitromethane. OTTO DIMROTH (*Ber.*, 1910, 43, 2767—2768).—Crystals of dibenzhydroxamic acid, m. p. 161°, were obtained in quantity from phenylnitromethane preparations which had been kept for a long time.

E. F. A.

Some New Derivatives of Diphenylmethane. LUIGI MASCARELLI, B. TOSCHI, and T. ZAMBONINI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 338—342. Compare Mascarelli, this vol., i, 725).—4:4'-Dichloro-2:2'-dinitrodiphenylmethane, obtained by means of the Sandmeyer reaction from the corresponding diamino derivative, forms slightly yellow, rhombic tablets, m. p. 121—122°. On reduction with tin and hydrochloric acid in alcoholic solution it yields 4:4'-dichloro-2:2'-diaminodiphenylmethane, which crystallises in colourless needles, m. p. 130—131°. When diazotised and treated with potassium iodide, it is converted into 4:4'-dichloro-2:2'-diiododiphenylmethane, which forms colourless crystals, m. p. 77—78°.

2:2'-Di-iodo 4:4'-tetramethyldiaminodiphenylmethane,

can be obtained, but only in small amount, by diazotising the corresponding amino-compound and treating it with potassium iodide. It forms colourless scales, m. p. 123°.

R. V. S.

Derivatives of isoNaphthfluoren (*o*-Phenylene- $\beta\beta$ -naphthyl-enemethane). JOHANNES THIELE and ALEXIS WANSCHIEDT (*Annalen*, 1910, 376, 269—279).—A modification of Kipping's method of preparing α -hydrindone (*Trans.*, 1891, 65, 485) from β -phenylpropionyl chloride (which is best prepared by warming β -phenylpropionic acid with thionyl chloride) is described, whereby the ketone is obtained in 95% yield. It reacts with *o*-phthalaldehyde and 10% sodium hydroxide in aqueous alcohol to form an additive compound, $\text{C}_{17}\text{H}_{11}\text{O}_3$, m. p. 185° (decomp.), which receives the annexed constitution (2 *o*-hydroxy-*o*-aldehydobenzyl-1-hydrindone) because it

reduces ammoniacal silver nitrate and is converted into isonaphthfluorenone (*o*-phenylene- $\beta\beta$ -naphthylene ketone) (*Abstr.*, 1909, i, 929)

by boiling methyl-alcoholic potassium hydroxide. A better method is described for the preparation of isonaphthfluorenone. It forms an *urine*, m. p. 231°, and by reduction with sodium amalgam or with zinc and potassium hydroxide, is converted into isonaphthfluorenol,

$\text{OH}\cdot\text{CH}<\text{C}_6\text{H}_4$, m. p. 185°. This alcohol forms an ether, $\text{O}(\text{C}_{17}\text{H}_{11})_2$ (?), m. p. about 300°, an acetate, m. p. 97°, and in glacial acetic acid is converted by hydrogen chloride into the chloride, $\text{C}_{17}\text{H}_{11}\text{Cl}$, m. p. 150°, and by hydrogen bromide in glacial acetic acid into the bromide, $\text{C}_{17}\text{H}_{11}\text{Br}$, m. p. 162° (decomp.), which is reduced to isonaphthylfluorene, $\text{C}_{17}\text{H}_{12}$, m. p. 208°, by zinc and acetic and hydrochloric acids. Diisonaphthylfluorenyl, C_{10}H_6
 C_6H_4 $\text{CH}\cdot\text{CH}<\text{C}_6\text{H}_4$, m. p. 260—270° (decomp.), is obtained by heating isonaphthylfluorenyl bromide and sodium iodide in acetone. Bisphenylene-bis- $\beta\beta$ -naphthylene-ethylene, C_{10}H_6
 C_6H_4 $\text{C}\equiv\text{C}<\text{C}_6\text{H}_4$, m. p. 232°, obtained by the interaction 5*N*-methyl-alcoholic potassium hydroxide and isonaphthylfluorenyl bromide in an excess of acetone, crystallises in dark red leaflets; it can also be prepared by heating isonaphthylfluorene or diisonaphthylfluorenyl with lead oxide at 300°, and is reduced to the latter by sodium amalgam and boiling amyl alcohol. C. S.

Dinaphthylmethane and Naphthylfluorene. JULIUS SCHMIDT and MAX HUBER (*Ber.*, 1910, 43, 2821—2837).—The three dinaphthylmethanes which are theoretically possible are all known, but the constitution of only one has been determined with certainty, namely, di- β -naphthylmethane, m. p. 92°, prepared by reducing di- β -naphthyl ketone (Richter, *Abstr.*, 1881, 281). It is now shown that the hydrocarbon obtained by Grabowski (*Abstr.*, 1875, 455) by condensing naphthalene with methylal in the presence of sulphuric acid is di- α -naphthylmethane, since it can be prepared from di- α -naphthyl carbinol by converting the latter into di- α -naphthylacetic acid, and distilling the acid when carbon dioxide is eliminated. The hydrocarbon described by Claus and Ruppel (*Abstr.*, 1890, 510) must therefore be $\alpha\beta$ -dinaphthylmethane.

The constitutions of the isomeric dinaphthaxanthenes have also been established. The three isomerides formed from β -naphthol must have the O-bridge in the β -position in both naphthalene rings. The compound with m. p. 149° (Claus and Ruppel, *loc. cit.*) yields $\alpha\beta$ -dinaphthylmethane when reduced, and must therefore be di-

naphthylene- $\alpha\beta$ -ketone- $\beta\beta$ -oxide, C_6H_4 — $\text{C}\equiv\text{CO}\cdot\text{C}\equiv\text{CH}$
 $\text{CH}\cdot\text{CH}\cdot\text{C}\equiv\text{O}\cdot\text{C}\equiv\text{CH}$ C_6H_4 . Bender's

β -dinaphthaxanthone, m. p. 194° (*Abstr.*, 1887, 37), must have the carbonyl group in the α -position with respect to one naphthalene ring (Kostanecki, *Abstr.*, 1892, 1098), and since it is not identical with Claus and Ruppel's xanthone, the carbonyl group must be in the α -position with respect to the second naphthalene ring, and the compound is therefore *dinaphthylene- $\alpha\alpha$ -ketone- $\beta\beta$ -oxide*,

γ -Dinaphthaxanthone, m. p. 241° (Kostanecki, *loc. cit.*), must be

dinaphthylene- $\beta\beta$ -ketone- $\beta\beta$ -oxide, C_6H_4 $\text{CH}\cdot\text{C}\equiv\text{CO}\cdot\text{C}\equiv\text{CH}$ C_6H_4 .

Di- α -naphthylacetic acid, $(C_{10}H_7)_2CH \cdot CO_2H$, obtained by converting di- α -naphthylcarbinol (Schmidlin and Massini, Abstr., 1909, i, 561) into the carbonyl chloride, and then condensing this with magnesium and carbon dioxide, has m. p. 223° , and when heated at 250 — 260° and then at 300° yields di- α -naphthylmethane, m. p. 105° (corr.). Grabowski's hydrocarbon has the same melting point, and in its preparation according to Grabowski's method appreciable amounts of a compound, $C_{40}H_{32}O$, are obtained.

β -Iodonaphthalene is prepared readily by a modification of Jacobson's method (Abstr., 1881, 736), and the magnesium β -naphthyl iodide reacts with a dry ethereal solution of ethyl formate, yielding a product which is decomposed by dilute acid, giving di- β -naphthylcarbinol, β -dinaphthylfluorene, naphthalene, and another product.

$\beta\beta$ -*Dinaphthylfluorene*, $\begin{matrix} C_{10}H_6 \\ C_{10}H_6 \end{matrix} > CH_2$ is somewhat sparingly soluble in cold ether, but is more soluble than the carbinol in hot light petroleum. It crystallises in large, colourless, macroous plates, m. p. 190.5° (corr.), and its solutions do not fluoresce. It is isomeric with Bamberger and Chattaway's picylenemethane (Abstr., 1895, i, 233), and when oxidised with an acetic acid solution of chromic anhydride yields $\beta\beta$ -*dinaphthylfluorenone*, $\begin{matrix} C_{10}H_6 \\ C_{10}H_6 \end{matrix} > CO$, which crystallises from ether in large, orange-coloured needles, m. p. 163 — 165° (corr.). The ketone dissolves in concentrated sulphuric acid, yielding deep blue-coloured solutions, which turn brown when kept. The isomeric *aa-dinaphthylfluorenone*, prepared by oxidising *aa*-dinaphthylfluorene (Schmidlin and Massini, *loc. cit.*), crystallises in minute, deep red-coloured needles, m. p. 255° , and dissolves in concentrated sulphuric acid to red solutions.

Di- β -naphthylcarbinol, $CH(C_{10}H_7)_2 \cdot OH$, crystallises from light petroleum (b. p. 110 — 150°) in nodular masses, m. p. 91° (corr.), containing petroleum of crystallisation. The carbinol also forms a definite compound with hexane, $C_{21}H_{16}O, 2C_6H_{14}$; this has m. p. 116.5° (corr.), and the hexane is removed when the crystals are heated at 150° under reduced pressure. The carbinol has not been obtained in a crystalline form free from hydrocarbon of crystallisation.

Di- β -naphthylchloromethane, $CH(C_{10}H_7)_2Cl$, obtained by the action of hydrogen chloride on a warm benzene solution of the carbinol, crystallises in colourless prisms, m. p. 167° (corr.). Its solution in concentrated sulphuric acid is colourless, but gradually assumes a violet coloration, due to the formation of the carbinol. It reacts with water or concentrated sulphuric acid less readily than the isomeric *aa*-compound does. *Di- β -naphthylacetic acid*, $CH(C_{10}H_7)_2 \cdot CO_2H$, crystallises from glacial acetic acid in felted needles, m. p. 182 — 183° (corr.), and yields a sparingly soluble sodium salt. In the preparation of the acid an appreciable amount of *tetra- β -naphthylethane*,

$CH(C_{10}H_7)_2 \cdot CH(C_{10}H_7)_2$, is formed. It crystallises from benzene in small prisms, m. p. 273.5° (corr.).

Tetra- α -naphthylethane (Schmidlin and Massini, *loc. cit.*), when

oxidised with chromic anhydride, yields an oxide, $C_{12}H_{28}O$, in the form of orange-red crystals, m. p. 257° .

Attempts to prepare di- α -naphthylketen-quinoline were unsuccessful.

Attempts to prepare tri- β -naphthylcarbinol by the action of β -naphthoyl chloride on magnesium β -naphthyl bromide gave an appreciable amount of an impure hydrocarbon, probably tri- β -naphthylmethane, m. p. 178° .

J. J. S.

Some Amide Derivatives of Thiocarboglycollic Acid. From HOLMBERG and B. PSILANDERHJELM (*J. pr. Chem.*, 1910, [ii], 82, 440—459). Compare this vol., i, 361).—In the production of rhodanins from dithiocarbamates and chloroacetamide (Miolati, Abstr., 1893, i, 403), the authors find that the amino-group of the acetic acid derivative is always eliminated by the ring closure, the thiocarbonyl group exhibiting remarkable stability. This conclusion is drawn from experiments on the behaviour of chloroacetamide and of chloroacetanilide on *N*-substituted dithiocarbamates; thus, chloroacetamide reacts easily with aqueous potassium phenyldithiocarbamate (prepared from aqueous potassium hydroxide, aniline, and carbon disulphide, a little *s*-diphenylthiocarbamide, which is formed, being removed by filtration) to form *N*-phenylrhodanin. Chloroacetanilide and aqueous ammonium dithiocarbamate give, according to the conditions of the experiment, either thiocarbonylthioglycollanilide (which is converted into rhodanine by hot dilute sulphuric acid) or a mixture of trithiocarbodiglycollanilide and thiodyglycollanilide; alcoholic chloroacetanilide and aqueous ammonium dithiocarbamate yield only thiodyglycollanilide. Chloroacetamide and aqueous potassium *o*-tolylidithiocarbamate yield *N*-*o*-tolylrhodanine.

Phenylmethylthiocarbonylthioglycollic acid, $CO_2H \cdot CH_2 \cdot S \cdot CS \cdot NPhMe$, m. p. $197-198^{\circ}$ (decomp.), is obtained by heating aqueous trithiocarbodiglycollic acid and methylaniline, or, much better, by treating aqueous potassium phenylmethyldithiocarbamate with aqueous sodium chloroacetate and acidifying after one day; it forms an ethyl ester, m. p. 77° . The amide, $NPhMe \cdot CS \cdot S \cdot CH_2 \cdot CO \cdot NH_2$, m. p. $141-141.5^{\circ}$, obtained from chloroacetamide and aqueous potassium phenylmethyldithiocarbamate, is converted into the free acid by hot dilute sulphuric acid, and into the ethyl ester by alcoholic sulphuric acid. The anilide, $NPhMe \cdot CS \cdot S \cdot CH_2 \cdot CO \cdot NHPh$, m. p. $139-139.5^{\circ}$, obtained from chloroacetanilide and potassium phenylmethyldithiocarbamate, is unchanged by hot dilute sulphuric acid, and is converted into the ethyl ester by alcoholic sulphuric acid.

Ethyl xanthoacetanilide, $OEt \cdot CS \cdot S \cdot CH_2 \cdot CO \cdot NHPh$, m. p. $91.5-92^{\circ}$, obtained from chloroacetanilide and potassium xanthate in aqueous alcoholic solution, and **ethyl trithiocarboglycollanilide**,

m. p. 98° , obtained from chloroacetanilide and potassium ethyl trithiocarbonate, do not yield *N*-phenylrhodanine by elimination of alcohol and ethyl mercaptan respectively.

C. S.

Isomerism in Compounds with Two Similar Asymmetric Nitrogen Atoms. EDGAR WEDEKIND and OTTO WEDEKIND (*Ber.*, 1910, 43, 2707—2719).—Trimethylene-bis(phenylmethylethylammonium

iodide), $\text{CH}_3(\text{CH}_2\cdot\text{NMeEtPhI})_2$, has been prepared in two ways: by the action of 2 mols. of methyl iodide on trimethylene-bis-ethylaniline, and by the addition of ethyl sulphate to trimethylene-bis-methylaniline, and interaction of the product with potassium iodide. In both cases the product obtained was a mixture of two isomeric iodides, a small quantity of a monomethiodide being also formed by the first method. The difference between the two iodides persists in their derivatives: those derived from the less fusible iodide are distinguished as *meso*-, those from the more fusible iodide as *para*-compounds. The *meso-iodide* has decomp. 222° , and crystallises in transparent prisms; the *para-iodide* forms opaque, prismatic aggregates (decomp. 177°). The *meso-platinichloride* forms monoclinic plates (decomp. 222°); the *isomeride* crystallises in monoclinic prisms, also m. p. 222° . The *meso-aurichloride* has decomp. 215° ; the *para*-compound, decomp. 205 – 206° . The *meso-picrate* has m. p. 129° , forming indefinite crystals; the transparent prisms of the *para-picrate* show m. p. 165° . The *meso-d-camphorsulphonate* forms prismatic needles, m. p. 118 – 120° ; the *para-isomeride* is very similar, m. p. 116 – 118° . The *meso-d-bromocamphorsulphonate* is crystalline, m. p. 163° ; the *isomeride* is amorphous.

It has not been possible to transform salts of one series into the other.

Fractional crystallisation of the camphorsulphonates and bromocamphorsulphonates did not resolve either base into optically active forms.

Trimethylene-bis-ethylaniline (compare Fröhlich, Abstr., 1907, i, 346) has b. p. 240 – $242^\circ/20$ mm.

Trimethylene-bis(*phenyldimethylammonium iodide*) crystallises in needles (decomp. 216°). E. F. A.

Electrolytic Reduction of Aromatic Sulphonyl Chlorides.

FRITZ FICHTER and WALTER TAMM (*Ber.*, 1910, 43, 3032–3038. Compare this vol., i, 20).—Suspensions of various aromatic sulphonyl chlorides in alcoholic sulphuric acid were reduced at a rotating lead cathode in a divided cell, the temperature being kept down by using a coiled lead tube, through which cold water flowed, as the anode. The most favourable current density varies from 0.04–0.07 ampere per sq. cm.; a further increase in the current density simply leads to the evolution of hydrogen. A copper cathode gives practically the same yield as one of lead, but with cathodes of silver, iron, zinc, nickel, or platinum the yield decreases in the order mentioned. Usually about one and a-half times the theoretical current was passed, the resulting product being a mixture of the disulphide, mercaptan, and sulphinic acid. To isolate these the reaction mixture was made alkaline with ammonia and the mercaptan oxidised by a current of air. After collecting the disulphide, sodium nitrite was added to the filtrate, and, after acidification with dilute sulphuric acid, a precipitate of the diarylsulphonylhydroxylamine derived from the sulphoic acid was obtained. These compounds are generally readily soluble in alkalis or alcohol, but sparingly so in benzene or ether.

α -Naphthalenesulphonyl chloride gave a yield of 81.3% of α -naphthyl disulphide and 13.6% of α -naphthalenesulphinic acid. The *di- α -naphthyl-*

sulphonylhydroxylamine, $(C_{10}H_7SO_2)_2N \cdot OH$, forms crystals, which have m. p. $120-130^\circ$ (decomp.). The solutions decompose on warming into tri- α -naphthylsulphonamide. β -Naphthalenesulphonyl chloride gave an 80% yield of the β -naphthyl disulphide and 12.6% yield of β -naphthalenesulphinic acid. *Di- β -naphthylsulphonylhydroxylamine* separated as almost colourless crystals from dilute alcohol; it decomposes at 134° . From benzene-1:3-disulphonyl chloride, dithioresorcin was isolated by extracting the weakly acid solution with ether; yield 20—25%. The yield of benzene-1:3-disulphinic acid was 50%. Molecular-weight determinations in acetone of the corresponding disulphonylhydroxylamine showed it to be *bis-m-phenylenedisulphonylhydroxylamine*, $C_6H_4 \begin{smallmatrix} SO_2 \cdot N(OH) \cdot SO_2 \\ SO_2 \cdot N(OH) \cdot SO_2 \end{smallmatrix} C_6H_4$; colourless crystals, de. composing at 212° .

p-Anisolesulphonyl chloride gave a 25.7—37% yield of *p*-methoxyphenyl disulphide. *Di-p-methoxybenzenesulphonylhydroxylamine* forms white needles, m. p. 120° (decomp.). *m*-Nitrobenzenesulphonyl chloride gave a 65—70% yield of *m*-aminophenyl disulphide sulphate.

The reaction mixture resulting from the interaction of sodium dimethylanilinesulphonate and phosphorus pentachloride was shown to contain the sulphonyl chloride by the preparation from it of *p*-dimethylanilinesulphonamide, $NMe_2 \cdot C_6H_4 \cdot SO_2 \cdot NHPh$; colourless crystals from alcohol, m. p. 176° . The crude reaction mixture containing the sulphonyl chloride gave *dithiodimethylaniline*, $S_2(C_6H_4 \cdot NMe_2)_2$, on electrolytic reduction; m. p. 118° . The yield is very small because of the instability of the sulphonyl chloride. T. S. P.

Theory of Organic Reactions. Molecular Compounds as Preliminary Products in Cases of Condensation. I. JULIUS SCHMIDLIN and RUDOLF LANG (*Ber.*, 1910, 43, 2806—2820. Compare Uroczynski and Gaye, this vol., ii, 699).—The authors accept Fittig's view that chemical reactions are preceded by the formation of more or less unstable additive compounds (compare Michael, *Abstr.*, 1888, 1055; 1900, i, 321; 1904, ii, 64), and attention is drawn to the fact that in the case of triphenylmethyl derivatives and nitrosodimethylaniline chemical reactivity is accompanied by capacity for formation of additive compounds.

The examples investigated have been those of condensations which take place readily in the presence of a condensing reagent without the application of heat. In such cases the question is not complicated to any appreciable extent by the formation of additive compounds between the reacting substances and the condensing agent. The following pairs of substances have been examined: phenol and acetone, resorcinol and acetone, quinol and acetone, catechol and acetone, pyrogallol and acetone, and phenol and cyclohexanone. In those cases in which condensation takes place with great readiness, it is found that additive compounds are formed, and that the relative amounts of the components in the additive compound are the same as the relative proportions in which they react to form the condensation product. Catechol and acetone, and also quinol and acetone, condense but slowly in the presence of concentrated hydrochloric acid and the additive compounds,

and condensation products bear no simple relationship to one another. In the latter case, the question is complicated by the formation of a definite compound of quinol with hydrogen chloride,

Similarly, the additive compounds and condensation products of pyrogallol and acetone, and of phenol and cyclohexanone, do not correspond.

In some cases the additive compounds have been actually isolated, and in all cases have been detected by melting-point curves.

Phenol and acetone yield the compound, $2Ph \cdot OH \cdot COMe_2$, in the form of long needles, m. p. 15° , and the condensation product, di- β -p-hydroxyphenylpropane, $CMe_2(C_6H_4 \cdot OH)_2$ (compare Dianin, Abstr., 1893, i, 214; Zincke and Grütters, *ibid.*, 1906, i, 172), which is formed most readily when cold concentrated sulphuric acid is used as condensing agent. When crystallised from benzene, it retains benzene on crystallisation, $3C_{12}H_{10}O_2 \cdot C_6H_6$, which it loses when heated at 80° under reduced pressure.

Resorcinol and acetone yield the compound, $C_6H_4(OH)_2 \cdot 2COMe_2$, m. p. 23° , which is comparatively stable. In determining melting points of mixtures of the two compounds, it is essential to avoid the entrance of traces of moisture, as such traces cause the mixtures to set to solid vitreous masses. The condensation product has not the composition stated by Causse (Abstr., 1892, 1312), but is to be represented as $C_{12}H_{11}O_6$. $C_6H_4(OH)_2 + 2CO(CH_3)_2 = C_{12}H_{14}O_2 + 2H_2O$, and has m. p. $230-240^\circ$.

Catechol and acetone yield a somewhat unstable compound,

m. p. -30° . The condensation product has the formula $C_{15}H_{14}O_4$, is formed in only small quantities, and decomposes at 270° . Quinol and acetone yield the compound, $C_6H_4(OH) \cdot COMe_2$, when sealed tubes are used (compare Habermann, Abstr., 1885, 53). Pyrogallol and acetone yield the compound, $C_6H_3(OH)_3 \cdot 3COMe_2$, m. p. -24° . The condensation product contains C = 68.4 and H = 6.3%.

The compound of phenol and cyclohexanone, $PhOH \cdot C_6H_{10}O$, has m. p. -23° , and the condensation product, 1:1-di-p-hydroxyphenylcyclohexane, $C_6H_{10}(C_6H_4 \cdot OH)_2$, obtained by using concentrated sulphuric acid, crystallises in colourless, rhombic plates containing alcohol, m. p. 186° (corr.).

α -Naphthol and cyclohexanone react with concentrated sulphuric acid, yielding a product, $C_{26}H_{22}O$, m. p. 232° . This appears to be the anhydride of di- α -hydroxynaphthylcyclohexane, $C_6H_{10} \begin{smallmatrix} C_{10}H_6 \\ C_{10}H_6 \end{smallmatrix} O$, and is insoluble in alkalis.

J. J. S.

An Easy Transformation of Asaryl Aldehyde into a Triphenylmethane Derivative. RUDOLF FABINYI and TIBOR SZÉKI (*Ber.*, 1910, 43, 2676-2684).—A good yield of nonamethoxytriphenylmethane, $CH[C_6H_3(OMe)_3]_3$, is obtained when asaryl aldehyde is heated with 25% hydrochloric acid for three hours on a water-bath. It may be freed from a brown, amorphous by-product by treatment with very dilute alkali hydroxide, and separates from alcohol in

colourless crystals, m. p. 184.5°. Its solution in sulphuric acid has a brilliant blue colour, and the crystals tend to turn yellow when kept in a calcium chloride desiccator. Concentrated nitric acid reacts with a glacial acetic acid solution of the nonamethoxy-derivative, yielding 4-nitro-1:2:5-trimethoxybenzene (Abstr., 1907, i, 45). Bromine reacts with a cold benzene solution of the nonamethoxytriphenylmethane according to the equation:

The 4-bromo-1:2:5-trimethoxybenzene crystallises from alcohol in colourless, monoclinic prisms [$\alpha:b=0.97506:1$; $\beta=50^\circ 56'$], m. p. 54.5°. The same compound can be prepared more readily by the action of bromine on asaronic acid, or by the bromination of hydroxy-quinol trimethyl ether. In the latter case, when an excess of bromine is used, dark blue, glistening crystals, $\text{C}_9\text{H}_{11}\text{O}_3\text{Br}_2$, are formed, but these are extremely unstable, and with water yield the bromotrimethoxybenzene. The second product, obtained by the action of bromine on the nonamethoxy-derivative, crystallises from benzene in slender prisms with a dark purple-blue colour, and is represented as a bromine additive compound of hexamethoxydiphenylmethane, namely,

$$\text{BrMeO}:\text{C} \begin{array}{c} \text{C}(\text{OMe})\text{:CH} \\ \text{CH}:\text{C}(\text{OMe}) \end{array} \text{C}:\text{CH}:\text{CBr} \begin{array}{c} \text{C}(\text{OMe})\text{:CH} \\ \text{CH}:\text{C}(\text{OMe}) \end{array} \text{C}:\text{OMeBr}.$$

This formula is supported by the fact that the compound reacts with water, yielding asarylaldehyde and bromotrimethoxybenzene, $\text{C}_{19}\text{H}_{23}\text{O}_6\text{Br}_3 + \text{H}_2\text{O} = \text{CHO}\cdot\text{C}_6\text{H}_3(\text{OMe})_3 + \text{C}_6\text{H}_2\text{Br}(\text{OMe})_3$.

Dibromotrimethoxybenzene, $\text{C}_6\text{H}_2\text{Br}_2(\text{OMe})_3$, prepared by the action of bromine on the monobromo-derivative, crystallises from benzene in long, colourless needles, m. p. 61°. 2:4:5:2':4':5'-Hexamethoxydiphenyl, $\text{C}_{12}\text{H}_4(\text{OMe})_6$, can be obtained from the bromotrimethoxybenzene and copper at 270°. It crystallises from alcohol, has m. p. 180°, and yields a greenish-blue, unstable, additive compound with benzene.

is formed by the action of silver cyanide on the bromine additive compound of hexamethoxydiphenylmethane: $\text{C}_{19}\text{H}_{23}\text{O}_6\text{Br}_3 + 3\text{AgCN} = \text{CN}\cdot\text{CH}[\text{C}_6\text{H}_2(\text{OMe})_3]_2 + 3\text{AgBr} + \text{C}_2\text{N}_2$, and crystallises from alcohol in slender needles, m. p. 155°.

Hydrogen chloride yields a deep blue additive compound with the nonamethoxytriphenylmethane, and when this is decomposed with water a colourless compound, m. p. 115–116°, is formed. J. J. S.

cycloButylcarbinol (ω -Hydroxymethylcyclobutane) and its Isomerisation Under the Influence of Acids into Pentane Derivatives. NICOLAUS J. DENJANOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 837–855. Compare Abstr., 1903, i, 403; Perkin, *Trans.*, 1901, 70, 329).—The most convenient method of obtaining *cyclobutylcarbinol*, $\text{C}_4\text{H}_7\cdot\text{CH}_2\cdot\text{OH}$, is by the reduction of ethyl *cyclobutane*-carboxylate with metallic sodium in alcoholic solution. When pure, it has b. p. 140–142.5°/750 mm., D_{20}^{20} 0.9199, D_{20}^{25} 0.9129, n_D^{20} 1.4449. When oxidised with chromic anhydride and sulphuric acid, it forms an aldehyde, of which the sodium bisulphite compound and a semi-

carbazone, m. p. 115—120°, were prepared in an impure state, and *cyclobutylcarbinyl cyclobutanecarboxylate*,

b. p. 218—220°, D_{15}^{20} 0.9795, n_D^{19} 1.4546, n_D^{21} 1.4533.

When heated with hydrogen bromide in a sealed tube at 100°, *cyclobutylcarbinol* is converted into *bromocyclopentane*,

b. p. 137—139°, D_{15}^{20} 1.385, n_D^{19} 1.4875, which by means of zinc palladium and hydrobromic acid is reduced to *cyclopentane*,

b. p. 49—50°/750 mm., D_{15}^{20} 0.7525, D_{20}^{20} 0.7513, $n_D^{18.5}$ 1.4087, n_D^{20} 1.4072.

Iodocyclopentane, $\begin{array}{c} \text{CH}_2 \cdot \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{CH}_2 \cdot \text{CH}_2 \end{array} \text{CHI}$, prepared similarly, is a colourless liquid, which turns green or brown when kept, has b. p. 162—164°/750 mm. (decomp.), D_4^{20} 1.7154, D_4^{20} 1.6825, n_D^{20} 1.5374, and with silver nitrate yields a secondary and a primary nitro-compound, which, without being isolated, were converted into the ψ -nitrole, $\text{NO} \cdot \text{C}_5\text{H}_9 \cdot \text{NO}_2$, m. p. 96°.

With oxalic acid, *cyclobutylcarbinol* yields a hydrocarbon, b. p. 43.5—44°/755 mm., seemingly identical in physical properties with that obtained from ω -aminomethylcyclobutane, and probably consisting of a mixture of *cyclopentene*, $\begin{array}{c} \text{CH}_2 \cdot \text{CH} \\ \diagup \quad \diagdown \\ \text{CH}_2 \cdot \text{CH}_2 \end{array} \text{CH}$, and a *dicyclopentene*,

$\begin{array}{c} \text{CH}_2 \cdot \text{CH} \\ \diagup \quad \diagdown \\ \text{CH}_2 \cdot \text{CH} \end{array} \text{CH}_2$, or of the latter only.

The unsaturated hydrocarbon gives a *dibromide*, b. p. 192—195°, and with sulphuric acid an *alcohol*, b. p. 137—138°/753 mm., which with chromic anhydride and sulphuric acid yields *cyclopentanone*, b. p. 130—131.5°, from which the oxime, m. p. 57°, and dihenzyl derivative, m. p. 189°, were prepared. The constitution of the unsaturated hydrocarbon and the isomerisation of *cyclobutanes* into *cyclopentanes* is discussed.

Z. K.

The Fluorene Series. A Correction. JULIUS SCHMIDT (*Ber.*, 1910, 43, 2778—2779).—The substance described as fluoreno ether by Schmidt and Stützel (this vol., i, 29) is, as Kliegl (this vol., i, 733) has in the meantime shown, a mixture of red diphenylene-ethylene and colourless diphenylenepheneanthrone.

E. F. A.

9-Formylfluorene or Diphenyleneacetaldehyde [Fluorene-9-aldehyde]. II. WILHELM WISLIZENUS and KARL RUSS (*Ber.*, 1910, 43, 2719—2734. Compare Abstr., 1909, i, 241).—In the pure state only the crystalline β -form and the polymeride of double molecular weight exist; the oily α -form is in reality the β -form hindered from crystallisation by impurities. Formylfluorene tends to polymerise when distilled; the vapour is unimolecular, but it polymerises during cooling. The enolic form is unstable, and no ferric chloride coloration is

produced. The enolic potassium compound gives no coloration, but a precipitate of ferric hydroxide.

The sodium bisulphite compound crystallises in colourless, flat needles, m. p. 151—152° (decomp.). The *O*-acetate crystallises in platelets, m. p. 132—133°, and forms a dibromide,

separating in colourless plates, m. p. 146—147° (decomp.). By the action of dry ammonia, a colourless compound, m. p. 148—149°, is formed, either iminomethylfluorene, $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{CH} \cdot \text{CH} \cdot \text{NH}$, or amino-

methylene-fluorene, $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{C} \cdot \text{CH} \cdot \text{NH}_2$. When heated above the melting point, a yellow compound is formed, which crystallises from nitrobenzene in small, golden-yellow prisms, m. p. 316—317°.

This dissolves in alcoholic potassium hydroxide or sodium ethoxide with a bluish-red coloration, which slowly disappears on standing; this colour change is attributed to conversion into the desmotropic form.

Formylfluorenenonoethylanilide, $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{C} \cdot \text{CH} \cdot \text{NEtPh}$, prepared by interaction of the components, crystallises in slender, canary-yellow prisms, m. p. 95—96°. The corresponding piperidine derivative, prepared in alcoholic solution, crystallises in yellow plates.

Formylfluorene- α -oxime, $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{CH} \cdot \text{CH} \cdot \text{N}(\text{OH})$, probably the *anti*-form, crystallises in colourless needles, m. p. 132—133°, colouring at 166°. The β -oxime, probably the *syn*-form, crystallises in similar needles, m. p. 166—167°.

9-Cyanofluorene [fluorene-9-carboxylonitrile], $\begin{array}{c} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{array} > \text{CH} \cdot \text{CN}$, produced by the action of thionyl chloride on the oxime, forms long, lustrous, colourless needles, m. p. 151—152°. It dissolves in warm sodium hydroxide with a yellow colour and bluish-green fluorescence.

Formylfluorenebenzoylhydrazide separates in lustrous, light yellow needles, m. p. 233—234°. On evaporation of solutions of the phenylhydrazone, an oxidation product, m. p. 155—156°, is formed, probably an azo-compound. This reacts with bromine, forming a *p*-bromobenzene-azomethylene-fluorene dibromide, $\text{C}_{20}\text{H}_{13}\text{N}_2\text{Br}_2$, crystallising in dark red needles, m. p. 210—211°. It is more easily obtained from formylfluorene-*p*-bromophenylhydrazone, which crystallises in lustrous, yellow plates, m. p. 158—159° (decomp.), and yields *p*-bromobenzeneazomethylene-fluorene, $\text{C}_{13}\text{H}_8 \cdot \text{CH} \cdot \text{N} \cdot \text{N} \cdot \text{C}_6\text{H}_4\text{Br}$, on oxidation, crystallising in lustrous, deep red needles with a blue reflex, m. p. 187—188°, and dissolving in concentrated sulphuric acid with an intense violet coloration.

Formylfluorenehydrazone forms colourless, lustrous, silky needles, m. p. 158—160°; it readily undergoes oxidation to azomethylene-fluorene, $\text{C}_{13}\text{H}_8 \cdot \text{CH} \cdot \text{N} \cdot \text{N} \cdot \text{CH} \cdot \text{C}_{13}\text{H}_8$, crystallising in very dark red, lustrous prisms, with a blue reflex, m. p. 290° (about).

Formylfluoreneacyanohydrin forms colourless, slender, silky needles,

m. p. 142—143°. When heated with concentrated hydrochloric acid in sealed tubes at 125°, *fluorene-9-glycollic acid*, $C_{13}H_9 \cdot CH(OH) \cdot CO_2H$, is formed in colourless plates, m. p. 194—195°. When boiled with potassium ethoxide, *cyanomethylenefluorene*, $\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix} > C:CH:CN$, is

obtained as a yellow, crystalline substance, m. p. 109—110°. It is remarkably stable towards hydrolysing agents.

By the action of bromine on formylfluorene an oil is produced. When dissolved in alcohol, the *acetal*, $C_{15}H_{19}O_2Br$, crystallises in colourless needles, m. p. 119—120°.

Di-biphenylenesuccinaldehyde, $\begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix} > C(CHO) \cdot C(CHO) < \begin{matrix} C_6H_4 \\ C_6H_4 \end{matrix}$, is obtained on oxidising formylfluorene with ferric chloride in acetic acid solution; it crystallises in colourless, lustrous prisms, m. p. 215—216°. Potassium ethoxide converts it into potassium formate and diphenylene-ethane, E. F. A.

Formation of an Ethylene Oxide from the Quaternary Base of Phenylmethylhydroxyethylamine. PAUL RABE and JULIUS HALLENSLEEN (*Ber.*, 1910, 43, 2622—2623. Compare this vol. i, 317).—It is shown that α -phenylpropylene $\alpha\beta$ -oxide is formed when the aqueous solution of Emde and Runne's (this vol. i, 479) base from the methiodide of α -amino- α -phenylisopropyl alcohol is heated.

The *oxide*, $\begin{matrix} CHPh \\ CHMe \end{matrix} > O$ (yield 40%), is a colourless liquid, b. p. 200°/752 mm., is heavier than water, and has a characteristic odour. J. J. S.

Unsaturated Hydroaromatic Acids with One Semicyclic Double Linking, and Their Derivatives. KARL AUWERS and G. PETERS (*Ber.*, 1910, 43, 3094—3110. Compare this vol. i, 826, 827).—When 1:3-dimethyl- Δ^3 -cyclohexon-5-one is condensed with ethyl bromacetate in presence of zinc and benzene, the product obtained is *ethyl 1:3-dimethyl- Δ^3 -cyclohexene-5-ol-5-acetate*,

b. p. 110°/2.5 mm. or 123°/4.5 mm. (decomp.), D_4^{25} 1.0126, $n_D^{17.6}$ 1.46857, n_D^{20} 1.47133, n_D^{25} 1.48411 (whence $\Sigma_v = +0.27$, $\Sigma_D = +0.20$, and $\Sigma_v - \Sigma_D = 7\%$), is a colourless, viscid oil, which when heated with dehydrating agents furnishes *ethyl 1:3-dimethyl- Δ^3 -cyclo-*

hexenylidene-5-acetate, $CH_2 < \begin{matrix} CMe=CH \\ CHMe-CH_2 \end{matrix} > C:CH \cdot CO_2Et$, b. p.

111—113°/5.5 mm. or 145—147°/15 mm., D_4^{20} 0.971—0.979, n_D^{20} 1.510—1.513, n_D^{25} 1.516—1.519, $\Sigma_v + 1.79$ to 2.15, $\Sigma_D + 1.87$ to 2.25, and $\Sigma_v - \Sigma_D$ 116 to 123%, which is identical with the substance wrongly assumed by Wallach and Böttcher to be ethyl $\Delta^{1,3}$ -dihydro-3:5-xylol-1-acetate, $CH_2 < \begin{matrix} CMe=CH \\ CHMe-CH \end{matrix} > C \cdot CH_2 \cdot CO_2Et$ (*Abstr.*, 1902, i, 798). On hydrolysis with sodium ethoxide, it yields the free acid,

m. p. 153—154°, and this when heated in closed tubes furnishes the corresponding hydrocarbon, 1:3-dimethyl-5-methylene- Δ^3 -cyclohexene (this vol., i, 826, and Wallach and Böttcher, *loc. cit.*). The acid is reduced with sodium amalgam in presence of carbon dioxide to 1:3-dimethyl- Δ^4 -cyclohexene-5-acetic acid, b. p. 154—155°/16.5 mm., D_4^{20} 0.9947, n_D 1.47428, n_D 1.47731, n_D 1.49068 (whence $\Sigma_a + 0.33$, $\Sigma_b + 0.27$, and $\Sigma_\gamma - \Sigma_c = 8\%$), a colourless oil, which is oxidised by permanganate to an acid, $C_8H_{12}O_3$, and on treatment with bromine followed by sodium hydroxide solution yields *s*-xylylacetic acid.

Ethyl 1:3-dimethyl- Δ^3 -cyclohexenylidene-5-acetate when treated with magnesium methyl iodide yields 1:3-dimethyl- Δ^3 -cyclohexene-5 trimethylcarbinol, $CH_2 \begin{array}{c} \text{CMe}=\text{CH} \\ \text{CHMe-CH}_2 \end{array} \text{C:CH} \cdot \text{CMe}_2 \cdot \text{OH}$, b. p. 125—126°/18 mm., D_4^{20} 0.922—0.934, n_D^{20} 1.503—1.506, n_D 1.508—1.510 (whence $\Sigma_a = +0.95$ to $+1.23$, $\Sigma_b = +1.00$ to 1.28 , and $\Sigma_\gamma - \Sigma_c = 48\%$), which, since it decomposes on heating, could not with certainty be prepared free from the hydrocarbon,

resulting from this decomposition. This hydrocarbon has b. p. 103—106°/17 mm., D_4^{20} 0.862—0.867, n_D^{20} 1.495—1.518, n_D 1.503—1.533, $\Sigma_a + 0.72$ to 1.86 , $\Sigma_b + 0.75$ to 2.02 , and $\Sigma_\gamma - \Sigma_c + 25$ to 93% . T. A. H.

Bismuth Benzoates. GODFRIN (*J. Pharm. Chim.*, 1910, [vii], 2, 385—396. Compare Rebière, *Abstr.*, 1896, ii, 396).—Bismuth benzoate and a series of basic bismuth benzoates are described, full details of their method of preparation being given.

Bismuth benzoate, $Bi(OBz)_3$, prepared by double decomposition between bismuth nitrate and sodium benzoate, both salts being dissolved in a mixture of water and glycerol, and a solution of benzoic acid in water being used for washing and re-crystallising the salt, forms bulky, brilliant, colourless, orthorhombic prisms, is stable up to 140°, and is decomposed by water, alcohol, or ether, forming basic salts. Treated in the cold with twenty times its weight of alcohol it furnishes a salt, $Bi_4O_3(OBz)_6$. This is a dead white powder, seen under the microscope to consist of minute, colourless, cubic crystals. It decomposes at about 160°. When treated with twenty times its weight of cold ether or a like quantity of alcohol at 95°, the neutral salt yields a new basic salt, $Bi_2O_3(BiO \cdot OBz)_{12}$, a white, partly crystalline powder. All the foregoing when treated with alcohol at 95° furnish the salt, $Bi_2O_3(BiO \cdot OBz)_6$, which consists of colourless, microscopic, monoclinic prisms. *Bismuthyl benzoate*, $BiO \cdot OBz$, crystallises in minute, monoclinic prisms. It is stable in air up to 140°, but when treated with alcohol at 95° it decomposes, like the other salts described, furnishing the salt $Bi_2O_3(BiO \cdot OBz)_6$. T. A. H.

Alkylation of Aromatic Amino-acids. IV. Nitroamino- and Iodoamino-acids. HENRY L. WHEELER and CARL O. JOHNS (*Amer. Chem. J.*, 1910, 44, 5, 441—452. Compare this vol. i, 381, 666).—The investigation of the behaviour of aromatic amino-acids on

ethylation is continued by a study of further acids. 4-Nitro-2-aminobenzoic acid gives a mixture of 40% of the primary amino-ester and 40% of the *N*-alkyl acid. 2-Nitro-4-aminobenzoic acid gives only the ester (43.4%). Both 4-iodo-*o*-aminobenzoic acid and 5-iodo-*o*-aminobenzoic acid give only *N*-alkyl acids (71—76%). 4 : 5-Di-iodo-*o*-aminobenzoic acid alkylates with difficulty, and gives only the ester (28%).

These results show that the tendency of amino-acids to react in an abnormal manner and give esters is not dependent on stereochemical interference.

An improved method for the preparation of 4-nitro-2-aminobenzoic acid is given; the ethyl ester melts at 100°.

4-Iodo-2-nitrobenzoic acid forms prisms, m. p. 192°. 4-Iodo-2-aminobenzoic acid crystallises in flat prisms, decomposing at 268°; 4-iodo-2-ethylaminobenzoic acid forms clusters of plates, m. p. 188°. 4-Iodo-2-methylaminobenzoic acid crystallises in needles, m. p. 197°.

4 : 5-Di-iodo-2-aminobenzoic acid begins to give off iodine at 200°; its ethyl ester forms slender needles, m. p. 137°. N. C.

Complete Methylation of Some Amino-acids. R. ENGELAND (*Ber.*, 1910, 43, 2662—2664. Compare Abstr., 1909, i, 856).—When a mixture of phenylalanine (α -amino- β -phenylpropionic acid), methyl-alcoholic potassium hydroxide, and methyl iodide is boiled gently for several hours, the chief product is *phenyl-N-trimethylalanine methyl ester*, the *platinochloride* of which, $2C_{13}H_{20}O_2NPtCl_6$, has m. p. 177—178°. The *aureichloride* of *phenyltrimethylalanine*,

forms golden-yellow needles, m. p. 94—95°.

When α -aminoglutaric acid is treated in a similar manner two products are obtained, the one forms a sparingly soluble *aureichloride*, $C_8H_{12}O_4N_3HAuCl_4$, probably derived from the dimethyl ester of dimethylglutamic acid, and the other an *aureichloride*,

in the form of readily soluble, hygroscopic crystals, probably derived from dimethylglutamic acid. J. J. S.

Synthesis of Compounds of the Normal Phenylpropane, Phenylbutane, and Phenylpentane Series. JULIUS VON BRAUN (*Ber.*, 1910, 43, 2837—2852).—The synthesis of compounds containing the group $C_6H_5 \cdot [CH_2]_x$ is important, since it is very probable that many resins contain such fatty-aromatic chains. Methods based on the interaction of sodium and aryl halides, or of aluminium chloride and aromatic hydrocarbons, on substances of the type

or $Cl \cdot [CH_2]_x \cdot OPh$ have proved unsatisfactory. γ -Bromopropylphthalimide and ϵ -chloroamylphthalimide are very resistant to the attack of sodium, but, contrary to expectation, react with aluminium chloride. The former yields only an additive compound, which is easily decomposed into its generators, but its formation suggests that the usual Friedel-Crafts' reaction might take place with a substance in which the acylated amino-group is removed further from the

halogen atom. This expectation is fulfilled, benzoyl- ϵ -chloroamylamine and benzoyl- ζ -chlorohexylamine reacting with aluminium chloride and benzene in the usual way. The product of the first reaction is *benzoyl- ϵ -phenylamylamine*, $C_6H_5 \cdot [CH_2]_5 \cdot NHBz$, b. p. 273—275°/15 mm., in 90% yield, which is hydrolysed by hydrochloric acid under pressure to *ϵ -phenylamylamine*, b. p. 131°/15 mm., a colourless liquid which has a faint basic odour, only slowly absorbs water and carbon dioxide from the air, and forms a *platinichloride*,

decomp. 220°, *picrate*, m. p. 152—153°, *benzoyl derivative*, m. p. 66° (the benzoyl derivative, as obtained in the preparation above, has not been made to crystallise), and a *methiodide*,

m. p. 181°, the *platinichloride* of which has m. p. 219°. The normal constitution of the ϵ -phenylamylamine, prepared from benzoyl- ϵ -chloroamylamine by the Friedel-Crafts' method, is proved by the synthesis of the base by the following series of reactions, which represent the fulfilment of the object of the author's work. γ -*Iodopropyl benzene*, $C_6H_5 \cdot [CH_2]_3I$, b. p. 137—140°/20 mm., obtained by the prolonged boiling of γ -chloropropylbenzene and sodium iodide in alcohol, is warmed with an aqueous alcoholic solution of potassium cyanide (2 mols.), whereby γ -*phenylbutyronitrile*, b. p. 142—145°/16 mm., is obtained; the nitrile, by reduction with sodium and alcohol (distilled over sodium and kept for many days, or, better, weeks over calcium), yields δ -*phenylbutylamine*, $C_6H_5 \cdot [CH_2]_4 \cdot NH_2$, b. p. 123—124°/17 mm. (*platinichloride*, decomp. 205°; *picrate*, m. p. 125°; the *N*-*dimethyl methiodide*, $C_6H_5 \cdot [CH_2]_4 \cdot NMe_2 \cdot MeI$, m. p. 191—192°), the *benzoyl derivative* of which, m. p. 83·5°, is converted by distillation with phosphorus pentachloride into δ -*chlorobutylbenzene*,

b. p. 122—123°/17 mm., in 75% yield. This substance, by reactions similar to the preceding, is converted successively into δ -*iodobutylbenzene*, b. p. 148—151°/15 mm., δ -*phenylvaleronitrile*, b. p. 157—161°/17 mm., and ϵ -phenylamylamine, which is identical with the base prepared above.

By distillation with phosphorus pentachloride, benzoyl- ϵ -phenylamylamine yields ϵ -*chloroamylbenzene*, $C_6H_5 \cdot [CH_2]_5Cl$, b. p. 134°/18 mm., which has a very pleasant odour, reacts with alcoholic sodium phenoxide to form *phenyl ϵ -phenylamyl ether*, b. p. 198°/14 mm., and with alcoholic sodium iodide to form ϵ -*iodoamylbenzene*, b. p. 158—165°/20 mm., in which the presence of the normal amyl chain is proved by the reaction of the iodide with alcoholic trimethylamine, whereby ϵ -phenylamyltrimethylammonium iodide, m. p. 181°, is obtained, identical with the salt produced by the exhaustive methylation of ϵ -phenylamylamine.

γ -Chloropropylbenzene is obtained readily from tetrahydroquinoline. The benzoylated base is ruptured by phosphorus pentachloride, and the resulting α - γ -chloropropylbenzanilide is hydrolysed to γ -chloropropylaniline, from which the amino-group is eliminated by diazotisation and subsequent treatment with alkaline stannous chloride. γ -Bromopropylbenzene, which is obtained quantitatively from dihydro-

benzyl alcohol and fuming hydrobromic acid at 105°, can only be prepared indirectly from γ -chloropropylbenzene; the latter is boiled for many hours with a large excess of alcoholic sodium phenoxide, and the resulting *phenyl γ -phenylpropyl ether*, $\text{CH}_3\text{Ph} \cdot [\text{CH}_2]_2 \cdot \text{OPh}$, b. p. 182—183°/17 mm., is heated with fuming hydrobromic acid.

C. S.

The Liberation of Carbon Monoxide from the Tertiary Acids Arising from the Condensation of Phenylpyruvic Acid with Aromatic Hydrocarbons. AUGUSTIN BISTRZYCKI and LOUIS MAURON (*Ber.*, 1910, 43, 2883—2889. Compare Abstr., 1907, i, 1039; Bistrzycki and von Weber, this vol., i, 742).—The investigation of the liberation of carbon monoxide from tertiary acids on treatment with concentrated sulphuric acid has now been extended to some benzyl-diarylacetic acids, which have now been prepared from phenylpyruvic acid and aromatic hydrocarbons, using cooled, concentrated sulphuric acid as the condensing agent, in the manner previously described (Bistrzycki and Reintke, Abstr., 1905, i, 285). The acids of this type evolve only two-thirds to three-quarters of the theoretical amount of carbon monoxide, the incompleteness of the reaction being due probably to partial sulphonation. The products obtained are completely soluble in water. Triarylethylenes, analogous to the diarylethylenes of Bistrzycki and Reintke (*loc. cit.*), were not obtained. None of the acids loses carbon dioxide on heating.

*β -Phenyl- α -di-*p*-tolylpropionic acid*, $\text{CH}_3\text{Ph} \cdot \text{C}(\text{C}_6\text{H}_4\text{Me})_2 \cdot \text{CO}_2\text{H}$, from toluene and phenylpyruvic acid, crystallises in colourless, lustrous needles or prisms, m. p. 176°. That the phenylpyruvic acid has not reacted in the desmotropic form (compare Ruhemann and Stapleton, *Trans.*, 1900, 77, 241) follows from the fact that the analogous anisole derivative yields di-*p*-anisyl ketone on oxidation (Lamoni, *Diss.*, Freiburg, Switzerland, 1910, 33). The *silver* salt, $\text{C}_{28}\text{H}_{21}\text{O}_2\text{Ag}$, was obtained as a white precipitate. The *methyl* ester, $\text{C}_{24}\text{H}_{24}\text{O}_2$, forms hexagonal prisms, m. p. 117°.

*α -Phenyl- β -di-*p*-ethylphenylpropionic acid*,

(from ethylbenzene), crystallises in rosettes of stout needles or in flat prisms, m. p. 183—184°. The *ethyl* ester, $\text{C}_{27}\text{H}_{26}\text{O}_2$, forms microscopic prisms, m. p. 61°.

*α -Phenyl- β -di-*o*-xylylpropionic acid*, $\text{CH}_3\text{Ph} \cdot \text{C}(\text{C}_6\text{H}_3\text{Me}_2)_2 \cdot \text{CO}_2\text{H}$ (from *o*-xylene), crystallises in four-sided prisms or in needles, m. p. 160°. The *methyl* ester, $\text{C}_{26}\text{H}_{22}\text{O}_2$, forms microscopic prisms, m. p. 96—97°.

Phenylpyruvic acid does not react with *m*-xylene under the conditions stated, or with mesitylene and naphthalene. Only in one instance was it possible to obtain with benzene an acid of the m. p. of the expected $\alpha\beta$ -triphenylpropionic acid, whilst the products from cumene and cymene were difficult to purify.

R. V. S.

Comparison of Certain Acids Containing a Conjugated System of Double Linkings. ANNIE LOUISE MACLEOD (*Amer. Chem. J.*, 1910, 44, 331—352).—Reimer (Abstr., 1907, i, 852) has

shown that when methyl cinnamylidenemalonate is treated with a Grignard reagent, $\alpha\delta$ -addition takes place, but on decomposing the product rearrangement occurs, and the hydrogen atom by which the magnesium has been replaced is found to occupy the α -position to the carboxyl group. Reimer and Reynolds (Abstr., 1908, i, 988) have shown that methyl α -phenylcinnamylideneacetate reacts less readily with organic magnesium compounds, and that the resulting products consist chiefly of ketones formed by the replacement of the methoxy-group and subsequent addition of a second molecule of the reagent in the $\alpha\delta$ -position. A study has now been made of α -methylcinnamylideneacetic and α -cyanocinnamylideneacetic acids.

α -Methylcinnamylideneacetic acid is pale yellow when first obtained, but becomes white on exposure to light. It has been found that when the yellow form is treated with a very small quantity of sodium amalgam, the yellow colour disappears, and the colourless acid remains. The substance to which the yellow colour is due is therefore present in only small amount, and may possibly be an isomeric form of the acid. When the acid is exposed to direct sunlight for about four days, it is converted into 2:4-diphenylcyclobutane-1:3-di- α -methyl-

acrylic acid, $\text{CO}_2\text{H}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CH}\begin{smallmatrix} \text{CHPh} \\ \text{CHPh} \end{smallmatrix}\text{CH}\cdot\text{CH}\cdot\text{CMe}\cdot\text{CO}_2\text{H}$, m. p.

253—254°, which forms small, transparent prisms, and, on oxidation with potassium permanganate, yields α -truxillic, benzoic, and oxalic acids; its methyl ester, m. p. 126.5—127°, crystallises in slender needles. The acid unites with bromine with formation of a product which appears to be a mixture of a di- and a tetra-bromide; the methyl ester gives a *tetrabromide*, m. p. 200—201°.

When methyl α -methylcinnamylideneacetate is treated with bromine in presence of a little iodine, a *tetrabromide*, m. p. 128°, is produced, whilst, in the absence of iodine, a *dibromide*, m. p. 81°, is obtained, which liberates iodine from alcoholic potassium iodide, thus showing that the bromine atoms are attached to adjacent carbon atoms. When a solution of this dibromide in acetone is oxidised with potassium permanganate in presence of acetic acid, small quantities of a *substance*, m. p. 131°, are produced, which contains halogen, but does not liberate iodine from alcoholic potassium iodide.

Ethyl α -cyanocinnamylideneacetate reacts readily with organic magnesium compounds with production of quantitative yields of $\alpha\delta$ -additive compounds. When this ester (1 mol.) is treated with magnesium ethyl bromide (2½ mols.) and the product is decomposed with hydrochloric acid, ethyl α -cyano- δ -phenyl- β -ethyl- Δ^7 -pentenoate, $\text{CHPh}\cdot\text{CH}\cdot\text{CHEt}\cdot\text{CH}(\text{CN})\cdot\text{CO}_2\text{Et}$, b. p. 220°/20 mm., is obtained as a yellow oil; on hydrolysis with potassium hydroxide, the *potassium salt* is obtained, from which the *acid* separates on the addition of hydrochloric acid as an uncrystallisable oil. On heating this acid with alcoholic potassium hydroxide for two days, it is converted into δ -phenyl- β -ethylallylmalonic acid,

m. p. 165°, which, when heated above its m. p., yields δ -phenyl- β -ethyl- Δ^7 -pentenoamide, $\text{CHPh}\cdot\text{CH}\cdot\text{CHEt}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}_2$, m. p. 101°, which forms slender needles.

Ethyl α -cyanocinnamylideneacetate reacts with magnesium phenyl bromide to form *ethyl α -cyano- β -diphenyl- Δ^7 -pentenoate*,
 $\text{CHPh}:\text{CH}:\text{CHPh}:\text{CH}(\text{CN})\cdot\text{CO}_2\text{Et}$,

b. p. $263^\circ/18$ mm.

Both α -cyano- and α -methyl-cinnamylideneacetic acids react readily with potassium hydrogen sulphite, yielding colourless, additive compounds which could not be isolated. E. G.

Unsaturated Compounds. VIII. Addition of Hydroxylamine to Unsaturated Acids containing Conjugate Double Linkings. THEODOR POSNER and KARL RONDE (*Ber.*, 1910, 43, 2665—2676. Compare Abstr., 1909, i, 583, 649; Riedel and Schulz, *ibid.*, i, 581).—In further proof of the constitution of β -benzoylamino- β -styrylpropionic [β -benzoylamino- δ -phenyl- Δ^7 -pentenoic] acid is adduced the fact that on oxidation benzoylaspartic acid is formed. Although β -benzoylamino- δ -phenyl- Δ^7 -pentenoic acid and its ester contain olefinic linkings, it has not been found possible to form additive compounds with hydroxylamine or bromine. The addition of hydroxylamine to styrylacrylic acid proceeds slowly, for example, 240 hours' boiling of the solution is required, whereas with cinnamic acid five hours is sufficient.

The addition of hydroxylamine to sorbic, piperic, and α -phenylstyrylacrylic acids and their esters has been studied. The compounds combine with hydroxylamine (compare Riedel and Schulz, *loc. cit.*); sorbic acid at much the same rate as styrylacrylic acid, piperic acid much less readily, as also α -phenylstyrylacrylic acid and all α -alkylated unsaturated acids.

β -Amino- δ -phenyl- Δ^7 -pentenoic acid can be obtained by prolonged boiling of β -hydroxylamino- δ -phenyl- Δ^7 -penteno-hydroxamoxime hydrate (Abstr., 1909, i, 649) with methyl alcohol. It has not been found possible to prepare Riedel and Schulz's β -hydroxylamino- δ -phenyl- Δ^7 -penteno-hydroxamic acid by the method they give; the product formed under these conditions is *styrylacrylhydroxamic acid*,

m. p. 146° .

Methyl sorbate, $\text{CHMe}:\text{CH}:\text{CH}:\text{CH}\cdot\text{CO}_2\text{Me}$, is a colourless liquid with a pleasant odour, and has b. p. $180^\circ/759$ mm. The ester reacts with a cold solution of hydroxylamine in methyl alcohol during the course of a week, yielding an oil which is probably β -hydroxylamino-hydroxosorbhydroxamoxime hydroxide. *Aminohydroxosorbic acid* (β -amino- Δ^7 -hexenoic acid) is formed when the above hydroxide is boiled with methyl alcohol, or when a mixture of the methyl ester and hydroxylamine is boiled for ten hours with methyl alcohol. The same product is also formed when free sorbic acid is used, but the boiling must then be continued for 240 hours; it is an oil, and yields a *benzoyl* derivative, $\text{CHMe}:\text{CH}:\text{CH}(\text{NH}\cdot\text{COPh})\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, which crystallises from alcohol, and has m. p. 152° .

Methyl piperate, $\text{CH}_2\text{O}:\text{C}_6\text{H}_5\cdot\text{CH}:\text{CH}:\text{CH}:\text{CH}\cdot\text{CO}_2\text{Me}$, is deposited from methyl alcohol in glistening crystals, m. p. 146° , and reacts with a hot methyl-alcoholic solution of hydroxylamine, yielding β -amino- α -hydropiperic acid (β -amino- δ -3:4-methylenedioxyphenyl- Δ^7 -pentenoic

acid), $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_5\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}(\text{NH}_2)\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, which crystallises from water in colourless needles, m. p. 231° (decomp.). A small amount of the same product is also formed when sorbic acid itself is used; it yields a benzoyl derivative, $\text{C}_{13}\text{H}_{17}\text{O}_2\text{N}$, m. p. 188° , and reacts with potassium cyanate, forming β -carbamido- α -hydroliperic acid, $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_5\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}(\text{NH}\cdot\text{CO}\cdot\text{NH}_2)\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, as glistening crystals, m. p. 211° . The carbamido-acid, when heated at 215° , yields 3:4-methylenedioxystyryldihydrouracil,

as a yellow, crystalline powder, m. p. 224° .

Methyl α -phenylstyrylacrylate, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CPh}\cdot\text{CO}_2\text{Me}$, forms yellow crystals, m. p. 79 – 80° , and when boiled for several days with hydroxylamine and methyl alcohol yields β -amino- α -diphenyl- Δ^7 -pentenoic acid, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}(\text{NH}_2)\cdot\text{CHPh}\cdot\text{CO}_2\text{H}$, which crystallises from water in colourless needles, m. p. 200° (decomp.). The benzoyl derivative, $\text{C}_{21}\text{H}_{21}\text{O}_3\text{N}$, forms colourless, glistening crystals, m. p. 222 – 5° , and β -carbamido- α -diphenyl- Δ^7 -pentenoic acid,

colourless, glistening needles, m. p. 197° ; the corresponding 5-phenyl-

4-styryldihydrouracil, $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\begin{matrix} \text{CHPh}\cdot\text{CO} \\ \text{NH}\cdot\text{CO} \end{matrix}\text{NH}$, forms a pale

yellow powder, m. p. 212 – 5° , after softening at 192° .

When cinnamylidenemalononic acid is heated with methyl alcohol and hydroxylamine, carbon dioxide is evolved, and β -amino- δ -phenyl- Δ^7 -pentenoic acid is formed, whereas the corresponding methyl ester reacts with a methyl-alcoholic solution of hydroxylamine at 0° , yielding a crystalline product, m. p. 72° , which is probably a hydroxylamino-hydroxamoxime hydroxide.

J. J. S.

A New Step in the Reduction of the Nitro-group. III. GUSTAV HELLER and FRIEDRICH FRANTZ (*Ber.*, 1910, 43, 2892–2899. Compare *Abstr.*, 1906, i, 585; 1908, i, 208).—Since in the numerous cases examined it has not been possible to obtain the compound containing a dihydroxylamine group, which is the first product of the reduction of α -nitromandelonitrile, substituted mandelonitriles have now been investigated. Of these, 5-chloro-2-nitromandelonitrile does not yield the characteristic molecular compound in solid form, although its presence in the liquid can be shown by the production of 5-chloroisatin on acetylation. In the case of 5-bromo-2-nitromandelonitrile, the desired substance is obtainable in the form of its hydrochloride, although with a poor yield, and its reactions correspond in all respects with the observations previously recorded. A further proof of the existence of the combination of di- and mono-hydroxylamine compounds follows from the fact that solutions of the above hydrochloride when kept deposit 5-bromo-2-nitrosomandelonitrile, so that evidently no tendency to the formation of an azoxy-compound exists.

5-Chloro-2-nitromandelonitrile, $\text{C}_8\text{H}_5\text{O}_3\text{N}_2\text{Cl}$, is prepared by adding a concentrated, aqueous solution of potassium cyanide to a solution of 5-chloro-2-nitrobenzaldehyde (Einhorn and Eichengrün, *Abstr.*, 1891, 1098) in glacial acetic acid, or by adding the aldehyde to twice its weight of anhydrous hydrocyanic acid. It forms rosettes

of needles, m. p. 85° , and also large prisms containing chloroform of crystallisation, m. p. $64-66^{\circ}$.

5-chloro-2-nitromandelic acid, $C_8H_6O_5NCl$, m. p. 134° , is obtained by evaporating the nitrile with twenty times its weight of hydrochloric acid almost to dryness. The methyl ester, $C_9H_7O_5NCl$, has m. p. $87-88^{\circ}$. With alcoholic ammonia, 5-chloro-2-nitromandelonitrile yields the ammonium salt of 5-chloro-2-nitrosobenzoic acid, which may be obtained from it by the action of dilute hydrochloric acid. The free acid crystallises in colourless needles, which become coloured towards 170° and melt at 179° . After reduction with zinc and acetic acid no precipitate was observed, but on addition of hydrochloric acid and acetic anhydride a dark-coloured oil separated, and the solution when kept yielded 5-chloroisatin. The oil was insoluble in cold sodium hydroxide, and therefore was not 5-chloro-*N*-acetoxyisatin.

5-bromo-2-nitromandelonitrile, prepared from 5-bromo-2-nitrobenzaldehyde, has m. p. 81° . When it is reduced with zinc and acetic acid in an atmosphere of hydrogen, the liquid being cooled with water and well stirred, the molecular compound of 5-bromo-2-mono- and 5-bromo-2-dihydroxylaminomandelonitrile hydrochloride, $C_{16}H_{10}O_5N_4Cl_2Br_2$, separates. After purification by precipitation with concentrated hydrochloric acid from solution in weaker acid, it crystallises in a mass of colourless, crooked needles, which become coloured at 130° and decompose towards 145° . The free compound can also be isolated. On keeping, an aqueous solution of the hydrochloride deposits a brown precipitate, which, when saponified with dilute sodium hydroxide, yields bromoanthroxanic acid and bromoisatin. These substances are obtained directly by heating the salt with concentrated hydrochloric acid. *5-Bromoisatin*, $C_8H_5O_2NBr$, forms yellow needles, m. p. 255° . *5-Bromoanthroxanic acid*, $C_8H_4O_5NBr$, crystallises in colourless needles. It melts at $202-203^{\circ}$, with evolution of gas and partial sublimation; the yellow residue darkens on further heating, and melts towards 253° with evolution of gas. Bromoanthroxanic acid is reduced by ammoniacal ferrous sulphate, and on acidification 5-bromoisatin is precipitated. The hydrochloride of the molecular compound yields on treatment with dilute sodium hydroxide a colourless compound, m. p. $186-187^{\circ}$, and an aminocarboxylic acid, probably 5-bromo-2-amino-mandelic acid, crystallising in colourless needles, which become coloured towards 230° . Acetylation of the molecular compound in presence of an excess of hydrochloric acid gives rise to 5-bromo-1-acetoxyisatin. Phenylhydrazine reacts with the hydrochloride, yielding 5-bromo-1-hydroxyisatinphenylhydrazone and 5-bromo-isatin-2-phenylhydrazone, $C_{11}H_{10}ON_3Br$, which forms dark red crystals, m. p. $242-243^{\circ}$.

5-Bromo-2-nitrosomandelonitrile, $C_8H_5O_2N_2Br$, which can be obtained (in addition to 5-bromoisatin) from the filtrate from the molecular compound in the preparation of the latter, crystallises in compact, colourless prisms, m. p. $225-226^{\circ}$. On hydrolysis it yields 5-bromoanthroxanic acid.

R. V. S.

Action of Amines on Phthalic Acid. VII. J. BISHOP TINGLE and S. J. BATES (*J. Amer. Chem. Soc.*, 1910, 32, 1319-1330).—In continuation of the work on the interaction of amines with phthalic

acid and its derivatives (Abstr., 1907, i, 692, 1044; 1909, i, 28, 798, 909; this vol., i, 263), a study has been made of phthalamic acids containing one or more chlorine atoms or nitro-groups in the benzene nucleus.

Di-m-toluidine and *di-p-chloroaniline* 3:6-dichlorophthalates, m. p. 176° and 215° respectively, form pale yellow crystals. An improved method is described for the preparation of 3:6-dichlorophthalanic acid and its anil. The anil has m. p. 201°, and not 191° as stated by Graebe (Abstr., 1900, i, 547). The acid is not affected by solutions of amines in benzene, but is readily converted into the anil by the action of 50% alcohol. This dehydrating action of alcohol has been discussed by Tingle and Rolker (Abstr., 1909, i, 29).

Tetrachlorophthal-o-toluidic acid, $C_6H_4Me \cdot NH \cdot CO \cdot C_6H_2Cl_4 \cdot CO_2H$, m. p. 218—220°, obtained by the action of *o*-toluidine on tetrachlorophthalic acid or anhydride, forms white, lustrous crystals.

Tetrachlorophthalanic acid, $NHPh \cdot CO \cdot C_6Cl_4 \cdot CO_2H$, m. p. 266°, obtained by boiling tetrachlorophthalanil (Graebe and Buenzod, Abstr., 1899, i, 763) with solution of potassium hydroxide or by the action of aniline on tetrachlorophthalic anhydride, forms white crystals; its sodium and potassium salts are colloidal, and yield soapy solutions. *Tetrachlorophthal-β-naphthylamic acid*, $C_{10}H_7 \cdot NH \cdot CO \cdot C_6Cl_4 \cdot CO_2H$, m. p. 287°, forms white crystals, and yields colloidal sodium and potassium salts. When the acid is heated for ten minutes at 260—270°, it is converted into the *β-naphthylimide*, $C_6Cl_4 \cdot \begin{smallmatrix} CO \\ \diagup \quad \diagdown \\ N \cdot C_{10}H_7 \end{smallmatrix} \cdot CO$, m. p. 287°, which is a white, crystalline substance.

When 3-nitrophthalanic acid, $NHPh \cdot CO \cdot C_6H_3(NO_2) \cdot CO_2H$, is heated at 100° with 50% alcohol, it is slowly transformed into a 3-nitrophthalodianilide, m. p. 233—234°, which appears to be isomeric with that obtained by Chambers (Abstr., 1903, i, 699) of m. p. 211—212°. 3-Nitrophthal-β-naphthylamic acid,

$C_{10}H_7 \cdot NH \cdot CO \cdot C_6H_3(NO_2) \cdot CO_2H$, m. p. 201—202°, obtained by the action of β-naphthylamine on 3-nitrophthalic anhydride, forms light yellow crystals.

4-Nitrophthalanic acid, obtained by heating the anil (Graebe and Buenzod, *loc. cit.*) with solution of potassium hydroxide or by treating aniline with 4-nitrophthalic anhydride, has m. p. 192°, and not 181° as stated by Bogert (Abstr., 1902, i, 98). The anil has m. p. 200—201° (Bogert gives 194°). When 4-nitrophthalanic acid is heated at 100° with 50% alcohol, it is partly transformed into the anil; in presence of aniline the same product is obtained, together with a small quantity of a compound, m. p. 199—200°, which is probably 4-nitrophthalodianilide, $NO_2 \cdot C_6H_3(CO \cdot NHPh)_2$.

On comparing the results of the transformation experiments with 3- and 4-nitrophthalanic acids, it is evident that the approximation of negative groups ($CO_2H \cdot CO_2H \cdot NO_2 = 1 : 2 : 3$) inhibits the formation of the anil and greatly favours that of the dianilide, whereas the reverse is the case when the nitro-group is in the 4-position. 4-Nitrophthal-β-naphthylamic acid, $C_{10}H_7 \cdot NH \cdot CO \cdot C_6H_3(NO_2) \cdot CO_2H$, m. p. 202—204°, prepared by the action of β-naphthylamine on 4-nitrophthalic anhydride, forms pale yellow crystals.

Camphoro-β-naphthylamic acid, $C_{10}H_7 \cdot NH \cdot CO \cdot C_8H_{14} \cdot CO_2H$, m. p. 220—221°, obtained by the action of β-naphthylamine on camphoric anhydride, and camphoranilic acid (Auwers, Abstr., 1900, i, 85) are not affected by prolonged heating with amines or with 50% alcohol.

E. G.

Synthesis of Ethyl cyclobutanehexacarboxylate. YUGI SHIBATA (*Ber.*, 1910, 43, 2619—2622).—Ethyl cyclobutanehexacarboxylate, $(CO_2Et)_2C \begin{smallmatrix} \diagup C(CO_2Et)_2 \\ \diagdown CH(CO_2Et) \end{smallmatrix} CH \cdot CO_2Et$, can be synthesised by the action of the disodium derivative of ethyl ethanetetracarboxylate (Bischoff and Rach, Abstr., 1885, 244) on ethyl dibromosuccinate (Gorodetzky, Abstr., 1888, 820) in the presence of dry ether at 0° and with vigorous automatic stirring. It crystallises from alcohol in large, monoelonic plates [$a:b:c = 1.565:1:1.542$; $\beta = 131^\circ 32'$], m. p. 80°. Unaltered ethyl ethanetetracarboxylate is deposited with the cyclobutane derivative, but can be removed mechanically, as it forms large, needle-shaped crystals.

An oily by-product formed during the condensation is Bischoff's ethyl ethylencetetracarboxylate, $C(CO_2Et)_2 \cdot C(CO_2Et)_2$. The condensation does not take place when the reagents are heated in sealed tubes at 120—130°, and the same products are formed when ethyl isodibromosuccinate is used.

J. J. S.

Rotatory Power of Usnic Acid and other Lichen Derivatives. III. HEINRICH SALKOWSKI (*Annalen*, 1910, 377, 123—126, Compare Abstr., 1901, i, 152; 1902, i, 228).—The values for $[\alpha]_D^{20}$ for the following substances are given: *d*-Usnic acid (from nineteen species of lichens), +461.9° to +521.9°; *l*-usnic acid (from thirteen species), -455.9° to -496.8°; kamschadalic acid, +26.42°; lepranthin, +70.5°; pleopsidic acid, -66.15°; protolichenosteric acid, +12.1°.

Barbatie acid, lecanarolic acid, and salazinic acid appear to be inactive.

In most cases chloroform solutions were used.

Gymnogrammen from *Gymnogramme chrysophylla* has an orange colour, m. p. 159°, and $[\alpha]_D^{20} + 12^\circ$.

J. J. S.

Ethyl Tannate. RODGER J. MANSING (*J. Amer. Chem. Soc.*, 1910, 32, 1312—1319).—The composition of gallotannic acid has hitherto been uncertain, owing to the fact that crystalline derivatives were not known, and the substance was therefore difficult to purify. The ethyl ester has now been prepared in two crystalline forms with different amounts of water of crystallisation.

On treating an alcoholic solution of gallotannic acid with dry hydrogen chloride, ethyl gallotannate, $C_{51}H_{22}O_{20} \cdot 5H_2O$, m. p. 157°, is obtained in the form of nodules of pale yellow, lustrous crystals. When hydrolysed with dilute hydrochloric acid or dilute potassium hydroxide, it yields ethyl alcohol, dextrose, and gallic acid. Estimations of the gallic acid and dextrose, and determinations of the molecular

weight by the ebullioscopic method have shown that ethyl gallotannate has the composition $C_{41}H_{27}O_{21}(OEt)_5 \cdot 5H_2O$, and that it is a glucoside in which one formula weight of dextrose and five formula weights of gallic acid are represented in one molecule of the ester. Gallotannic acid is therefore represented by the formula $C_{41}H_{27}O_{21}(OH)_5$.

The ester was synthesised by treating a mixture of ethyl gallate and dextrose with phosphoryl chloride.

If a saturated solution of the ester is allowed to evaporate at the ordinary temperature, large, pale brown crystals are obtained of the composition $C_{51}H_{52}O_{26} \cdot 15H_2O$, m. p. 132° . F. G.

Theory of the Phenomena of Halochromy. I. Additive Compounds of Tin Halogenides and Carbonyl Compounds PAUL PFEIFFER [with O. HALPERIN, E. PROS, and V. SCHWARZKOPF] (*Annalen*, 1910, 376, 285—310).—The first step in the elucidation of the constitution of the coloured additive compounds of organic substances and metallic salts and acids, and therewith the nature of the phenomenon of halochromy, must be a systematic examination of the additive capacity of simply constituted substances. Since halochromy is most frequently observed in connexion with carbonyl compounds, these have been selected as the organic components; the inorganic are tin tetrachloride and tetrabromide, which have the property of forming well-characterised molecular compounds of simple composition.

The additive compound is obtained by bringing the tin halogenide and the carbonyl compound (aldehyde, ketone, acid, ester, or amide, containing generally the benzoyl or cinnamoyl group; acid chloride do not form additive compounds) together in anhydrous ether, benzene, or chloroform; in the case of liquid esters, a solvent is dispensed with. In this way have been prepared the following colourless compounds: $SnCl_4 \cdot 2PhCHO$, m. p. $187-189^\circ$; $SnBr_4 \cdot 2PhCHO$, m. p. $127-128^\circ$; $SnCl_4 \cdot 2CHPh \cdot CH : CH \cdot CHO$, m. p. $225-230^\circ$;

$SnBr_4 \cdot 2CHPh \cdot CH : CH \cdot CHO$,
m. p. 195° ; $SnCl_4 \cdot 2(p)OH \cdot C_6H_4 \cdot CHO$, m. p. 185° ;

$SnCl_4 \cdot 2(p)OMe \cdot C_6H_4 \cdot CHO$,
m. p. 158° ; $SnCl_4 \cdot 2COPhMe$, m. p. $131-133^\circ$; $SnCl_4 \cdot 2Ph \cdot CO \cdot Et$,
m. p. 40° ; $SnCl_4 \cdot 2(p)C_6H_4 \cdot Me \cdot CO_2Et$; $SnCl_4 \cdot 2CHPh \cdot CH : CH \cdot CO \cdot Et$,
m. p. 134° ; $SnBr_4 \cdot 2(o)OH \cdot C_6H_4 \cdot CO_2Me \cdot 2H_2O$, m. p. $67-68^\circ$.
 $SnCl_4 \cdot 2Ph \cdot CO_2H$, m. p. about 90° ; $SnCl_4 \cdot 2CHPh \cdot CH : CH \cdot CO_2H$,
m. p. $85-112^\circ$; $SnCl_4 \cdot 2Ph \cdot CO \cdot NH_2$, m. p. about 227° ;

$SnCl_4 \cdot 2CHPh \cdot CH : CH \cdot CO \cdot NH_2$,
m. p. $238-239^\circ$; $SnCl_4 \cdot 2(o)OH \cdot C_6H_4 \cdot CO \cdot NH_2$, m. p. 203° ; and also
the following, which are yellow or yellowish: $SnCl_4 \cdot 2C_4H_9 \cdot CHO$,
unstable; $SnBr_4 \cdot 2(p)OH \cdot C_6H_4 \cdot CHO$, m. p. 154° ;

$SnCl_4 \cdot 2CHPh \cdot CH : CH \cdot COMe$,
m. p. 120° . All these compounds are decomposed by water, and contain 1 molecule of the inorganic to 2 of the organic component. Their composition may be represented, therefore, by the general expression $SnX_4 \cdot 2R \cdot CO \cdot A$, where X is chlorine or bromine, R is Ph , C_6H_4 , OH , $C_6H_4 \cdot OMe$, $CHPh \cdot CH$, or C_4H_9 , and A is H , Me .

(OH, OEt, or NH_2). The common constituent of all these compounds is the carbonyl group, which therefore is the means by which the organic and the inorganic components are linked. The co-ordination number of tin is six. Moreover, additive compounds of the tin series are formed, almost without exception, extra-molecularly, not intra-molecularly. Therefore the two organic molecules of the additive compound probably occupy the two free co-ordination positions of the SnX_4 molecule, being linked by the oxygen, since tin has a much greater affinity for oxygen than for carbon. These views lead to the constitution $\text{X}_4\text{Sn} \begin{smallmatrix} \nearrow \text{O:CRA} \\ \searrow \text{O:CRA} \end{smallmatrix}$ for the preceding additive compounds.

These views, in conjunction with Thiele's theory, are utilised by the author to explain the facts that in a compound containing an unsaturated group the saturation of this group tends to diminish the colour intensity, whilst by the formation of a molecular additive compound colour is produced or intensified. For example, a substance,

$\begin{smallmatrix} \text{R} \\ \text{R} \end{smallmatrix} > \text{C}=\text{O}$, in virtue of the residual affinities of the carbon and oxygen atoms, is converted by the addition of $\text{Y}\cdot\text{Y}$ into a more saturated system, $\begin{smallmatrix} \text{R} \\ \text{R} \end{smallmatrix} > \text{CY}\cdot\text{OY}$, with a corresponding diminution or loss of colour;

this is not surprising, because, according to modern views, the colour of purely organic substances is due primarily to the presence of unsaturated groups. When, however, an extramolecular additive compound, such as those above, is formed by a neutralisation of the residual affinity of the oxygen atom only, the unsaturated carbon atom acquires a more pronounced unsaturated character, approximating to that of tervalent carbon, and therefore may be regarded as a specific chromophore, and the additive compound, under suitable circumstances, may be coloured or exhibit halochromy.

In the author's opinion the action of catalysts in hydrolysis, esterification, ketone-synthesis, etc., may be explained by the initial formation of a molecular compound of the catalyst and the organic substance at its carbonyl oxygen atom. C. S.

Action of Chloride of Sulphur and of Sulphuryl Chloride on Piperonal. KARL WEISSE (*Ber.*, 1910, 43, 2605—2606. Compare D.R.-P. 165727).—Piperonal reacts to only a slight extent when distilled with sulphuryl chloride, but when a mixture of the two compounds is kept at the ordinary temperature for two days a good yield of *chloropiperonal*, $\text{C}_8\text{H}_5\text{O}_3\text{Cl}$, is obtained; it crystallises from alcohol in brilliant needles, m. p. 114—115°.

When this chloro-derivative is heated with chloride of sulphur at 150° for an hour, and then at 130° for three hours, a resinous product is obtained, which loses carbon dioxide when heated, forming *chloroprotocatechualdehyde*, $\text{C}_7\text{H}_5\text{O}_3\text{Cl}$, m. p. 211°.

Chloroprotocatechualdehyde reacts with an alcoholic potassium hydroxide solution of ethyl chlorocarbonate, yielding the *ethyl carbonate* derivative, $\text{C}_{10}\text{H}_9\text{O}_5\text{Cl}$, which crystallises from water in glistening plates, m. p. 135°.

J. J. S.

Condensation Products of *o*-Phthalaldehyde. III. JOHANNES THIELE and ERNST WEITZ (*Annalen*, 1910, 377, 1—22. Compare Thiele and Falk, *Abstr.*, 1906, i, 750; Thiele and Schneider, *Abstr.*, 1909, i, 929).—Ketones with the grouping $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_3$ can react with *o*-phthalaldehyde in two distinct ways: (a) formation of a hydrindone derivative, as in the case of acetone or acetophenone; (b) formation of a benzocycloheptadienone, as in the case of diethyl ketone.

It is shown that methyl ketones which contain a normal carbon chain react according to the latter scheme; thus methyl ethyl, methyl propyl, and methyl *n*-butyl ketones yield respectively methyl-, ethyl-, and propyl-benzocycloheptadienones, $\text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{CH:CR} \\ \text{CH:CH} \end{smallmatrix}\rangle\text{CO}$. Naphthalene derivatives do not appear to be formed, but small amounts of acylhydrindones can be detected among the condensation products. Methyl isobutyl ketone yields as chief condensation product isovalerylhydrindone, and practically no isopropylbenzocycloheptadienone. Methyl isopropyl ketone yields isobutyrylhydrindone, as there is no methylene group present capable of yielding a benzocycloheptadienone derivative.

Phthalaldehyde also condenses readily with nitromethane, yielding nitrohydrindone, which reacts in the enolic form, nitrohydroxyhydrindene, as it yields an acetyl derivative and a methyl ether. Its constitution has been determined by conversion into Gabriel's amino hydrindone.

Benzocycloheptadienone, $\text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{CH:CH} \\ \text{CH:CH} \end{smallmatrix}\rangle\text{CO}$, prepared by heating the carboxylic acid (*Abstr.*, 1909, i, 930) with 0.5% hydrochloric acid at 200° for four to five hours, crystallises from light petroleum in pale yellow plates, m. p. 66—67°, and does not react with phenylhydrazine or hydroxylamine. The dibromide, $\text{C}_{11}\text{H}_{18}\text{OBr}_2$, forms colourless needles, m. p. 204°. Dimethylbenzocycloheptadienone,

prepared from diethyl ketone and phthalaldehyde in the presence of methyl-alcoholic potassium hydroxide solution, crystallises from dilute alcohol in colourless plates, m. p. 85°; diphenylbenzocycloheptadienone, $\text{C}_{23}\text{H}_{18}\text{O}$, obtained when dibenzyl ketone is used, crystallises in pale yellow prisms, m. p. 118.5°, and does not yield a dibromide; methylbenzocycloheptadienone, $\text{C}_{13}\text{H}_{10}\text{O}$, crystallises from light petroleum (40—70°) in felted needles, m. p. 61°; the corresponding ethyl derivative, $\text{C}_{13}\text{H}_{12}\text{O}$, has m. p. 42—43°, and the *n*-propyl derivative, $\text{C}_{14}\text{H}_{14}\text{O}$, has b. p. 188°/13 mm., and solidifies when kept in a freezing mixture.

Diphenylmethylbenzocycloheptanone, $\text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{CH}_2\cdot\text{CHPh} \\ \text{CH}_2\cdot\text{CHPh} \end{smallmatrix}\rangle\text{CO}$, prepared by reducing the corresponding dienone with sodium amalgam and alcohol in the presence of acetic acid, crystallises from 75% alcohol in colourless needles, m. p. 158°. The ketone does not react with phenylhydrazine or semicarbazide, but with magnesium methyl iodide yields diphenylmethylbenzocycloheptanol, $\text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{CH}_2\cdot\text{CHPh} \\ \text{CH}_2\cdot\text{CHPh} \end{smallmatrix}\rangle\text{CMe}\cdot\text{OH}$, which

forms colourless crystals, m. p. 211° , and is stable towards permanganate.

Dimethylbenzocycloheptanol, $C_6H_4 \begin{smallmatrix} \text{CH}_2 \cdot \text{CHMe} \\ \text{CH}_2 \cdot \text{CHMe} \end{smallmatrix} \text{CH} \cdot \text{OH}$, obtained by reducing the corresponding dienone, crystallises from dilute alcohol in colourless needles, m. p. $123-124^{\circ}$, and yields an *acetyl* derivative, m. p. 141° . *Diphenylbenzocycloheptanol*, $C_{22}H_{22}O$, forms colourless plates, m. p. 160° . *Benzocycloheptanol*, $C_6H_4 \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{smallmatrix} \text{CH} \cdot \text{OH}$, prepared from benzocycloheptadienone, has m. p. about 80° .

isobutyrylhydrindone (1-hydroxy-2-isobutyrylhydrindene),

crystallises from methyl alcohol in needles, soluble in alkalis, and gives a red to reddish-violet coloration with ferric chloride. When a small amount of alkali is used in the condensation, much phenylnaphthylene ketone is formed. *isobutyrylhydrindone* (1-hydroxy-2-isobutyrylhydrindene), $C_6H_4 \begin{smallmatrix} \text{C(OH)} \\ \text{CH}_2 \end{smallmatrix} \text{C} \cdot \text{CO} \cdot \text{CHMe}_2$, has b. p. $170-174^{\circ}/13-14 \text{ mm.}$, and m. p. $35-36^{\circ}$.

2-Nitro-1-hydrindone (2-nitroindanol), $C_6H_4 \begin{smallmatrix} \text{C(OH)} \\ \text{CH}_2 \end{smallmatrix} \text{C} \cdot \text{NO}_2$, crystallises from light petroleum (100°) in slender, sulphur-yellow needles, m. p. about 117° (decomp.). It dissolves in alkali hydroxide solutions and is decomposed when boiled with water. The *acetyl* derivative, $C_{11}H_9O_4N$, crystallises in slender, yellow needles, turns dark coloured at $108-109^{\circ}$, melts and decomposes above 120° , and yields a *dibromide*, $C_{11}H_7O_4NBr_2$, in the form of colourless, compact crystals, m. p. 136° . The *methyl ether* of the nitro-derivative, $C_9H_9O_3N$, is obtained readily from the acetyl derivative by the action of methyl alcohol and hydrogen chloride; it crystallises in pale yellow plates, m. p. 83° .

Hydrobenzoin-o-dialdehyde, $\text{CHO} \cdot C_6H_4 \cdot \text{CH(OH)} \cdot \text{CH(OH)} \cdot C_6H_4 \cdot \text{CHO}$, prepared by reducing phthalaldehyde with zinc dust in the presence of alcohol and glacial acetic acid at the ordinary temperature, crystallises from alcohol in minute needles, m. p. $176-177^{\circ}$. Its solution in concentrated sulphuric acid has an intense yellow colour with a greenish-yellow fluorescence. Its *phenylhydrazine*, $C_{25}H_{20}O_4N_4$, crystallises from aniline, and has m. p. above 260° . When oxidised with nitric acid the dialdehyde yields hydrodiphthalyl (compare Hasselbach, Abstr., 1888, 485), but with alkaline permanganate yields benzil-o-dicarboxylic acid (Graebe, Abstr., 1888, 1095; 1890, 989). Concentrated sulphuric acid reacts with a solution of the dialdehyde in glacial acetic acid, yielding 2-o-aldehydophenyl-3-indone, $C_6H_4 \begin{smallmatrix} \text{CO} \\ \text{CH} \end{smallmatrix} \text{C} \cdot C_6H_4 \cdot \text{CHO}$, which crystallises from alcohol in brilliant, orange-red needles, m. p. 141° . An amorphous by-product is formed at the same time, and the amount of this increases if the reaction mixture is heated for some time. The indone derivative reduces ammoniacal silver nitrate solution and also alkaline permanganate, and yields a *dibromide*, $C_{16}H_{10}O_2Br_2$, m. p. above 246° . A small amount of this indone is formed in the preparation of phthalaldehyde.

J. J. S.

Synthesis of Ketones, in the Tetrahydroaromatic Series. GEORGES DARZENS and H. ROST (*Compt. rend.*, 1910, 151, 758—759).—This paper contains an account of further applications of the general reaction already described (this vol., i, 322) to cyclohexene. By treating this hydrocarbon with *n*-butyryl chloride in presence of aluminium chloride, a condensation product is obtained, which loses hydrogen chloride when heated with diethylamine, forming *n*-butyrylcyclohexene, $C_3H_7 \cdot CO \cdot C_6H_{10}$, b. p. 225—226°, 113—114°/7 mm.; the semicarbazone has m. p. 171°. isobutyrylcyclohexene has b. p. 233°, 128—130°/7 mm.; the semicarbazone has m. p. 180°. Heptylcyclohexene has b. p. 274—275°, 140—141°/5 mm.; the semicarbazone has m. p. 145°. Laurylcyclohexene, b. p. 342—343°, 209—211°/6 mm., forms a semicarbazone, m. p. 125°.

The foregoing ketones may be utilised for the production of hexa-hydroaromatic ketones, the reduction being effected by catalytic hydrogenation in presence of reduced nickel.

By condensing tetrahydroacetophenone with ethyl chloroacetate in presence of sodium ethoxide, ethyl methylcyclohexenylglycidate, $O \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} CMe \cdot C_6H_9 \\ CH \cdot CO_2Et \end{smallmatrix}$, has been obtained. This substance has b. p. 145—146°/14 mm., and on hydrolysis gives an unstable acid, which loses carbon dioxide when heated in a vacuum, forming tetrahydroatropaldehyde, $C_6H_9 \cdot CHMe \cdot CHO$, b. p. 90—93°/15 mm.

W. O. W.

The Pinacone Transformation in the Case of Cyclic Compounds. I. HANS MEERWEIN and WALTER UNSKEL (*Annalen*, 1910, 376, 152—153).—1-isopropylcyclopentane-1 : α -diol,

prepared by the action of magnesium methyl iodide on methyl α -hydroxycyclopentanecarboxylate, readily undergoes the pinacone transformation when heated with dilute sulphuric or oxalic acid.

An intermediate product is probably the oxide, $\begin{array}{c} CH_2 \cdot CH_2 \\ | \quad | \\ CH_3 \cdot CH_2 \end{array} > C \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} CMe_2 \\ O \end{smallmatrix}$, but the final product isolated is 1 : 1-dimethylcyclohexan-6-one, the constitution of which was determined by oxidation to *aa*-dimethyladipic acid by means of nitric acid. The reaction (cyclic pinacone transformation) consists in the conversion of a 5-carbon into a 6-carbon ring, and is of interest as bearing on certain transformations in the terpene series.

Reactions of the same type are the conversion of pulegonic acid (isopropylidenemethylcyclopentanecarboxylic acid) into pulenone (1 : 4 : 4-trimethylcyclohexan-5-one) (compare Wallach, *Abstr.*, 1904, i, 74); also the conversion of dicyclopentanepinacone into 1 : 1-tetramethylenecyclohexan-2-one (Meiser, *Abstr.*, 1899, i, 742), and the transformation of fluorenone into a phenanthrene derivative when reduced with zinc and acetyl chloride, a pinacone being the intermediate product, which has not been isolated :

(compare Klinger and Lonnes, *Abstr.*, 1896, i, 691).

Methyl cyclopentan-1-ol-1-carboxylate,

is readily prepared from the acid (Gärtner, Abstr., 1893, i, 557) by the usual method. It has b. p. $87^\circ/23$ mm., or $84^\circ/16$ mm. 1-iso*Propylcyclopentane-1:α-diol*, $\text{C}_8\text{H}_{16}\text{O}_2$, crystallises from light petroleum in glistening, colourless prisms, m. p. 62° , and b. p. $105\text{--}110^\circ/15$ mm.

1:1-*Dimethylcyclohexan-6-one*, $\text{CH}_2 < \begin{array}{c} \text{CH}_2 \text{---} \text{CO} \\ | \quad | \\ \text{CH}_2 \cdot \text{CH}_2 \end{array} > \text{CMe}_2$, is a colourless oil, and yields a *semicarbazone*, $\text{C}_{10}\text{H}_{17}\text{ON}_3$, which crystallises in large, flat needles, m. p. $196\text{--}197^\circ$. The pure ketone, prepared by hydrolysing the semicarbazone with 10% sulphuric acid, has b. p. $59\text{--}61^\circ/14$ mm. or $170\text{--}2\text{--}170\text{--}4^\circ/758$ mm., D_{20}^{20} 0.9194, and n_D^{20} 1.44744, and has an odour of camphor and menthone.

A small amount of an unsaturated hydrocarbon accompanies the crude ketone.

J. J. S.

Reaction between Organic Magnesium Compounds and Unsaturated Compounds Containing Alkyloxy-groups. GRACE POTTER REYNOLDS (*Amer. Chem. J.*, 1910, 44, 305—331).—The reactions between organic magnesium compounds and unsaturated compounds have been studied by Kohler (Abstr., 1905, i, 208; 1907, i, 139, 1050) with special reference to the effect of hydrocarbon residues in substances containing the chain $\text{C}:\text{C}:\text{C}:\text{O}$, as the result of which it is possible to predict the mode of addition of a magnesium compound to such a substance. It has also been shown that in the reactions with ethyl α -cyanocinnamate (Abstr., 1905, i, 347) and ethyl benzylidenemalonate (Abstr., 1905, i, 700) the presence of the cyano- and carbethoxy-groups in the α -position prevents the replacement of the alkyloxy-group, and therefore only *additive* products are obtained. In continuation of this work, an investigation has been made of the influence of alkyloxy-groups on the mode of addition. An attempt has been made to use the Grignard reagent for the study of keto-enol-tautomerism, but it has been found to be unsuitable for the purpose.

Magnesium methyl iodide reacts instantaneously with phenyl formylethyl ketone when dissolved in ethyl ether, but does not react with it in an amyl ether solution, and it is therefore evident that the method cannot be used for the estimation of the hydroxyl group in this ketone (compare Hibbert and Sudborough, *Trans.*, 1904, 85, 933, and Zerewitinoff, Abstr., 1907, ii, 509).

Ethyl hydroxymethylenemalonate and phenyl formylethyl ketone were selected for the experiments to ascertain whether the nature of the products obtained in the Grignard reaction can serve for the estimation of the relative amounts of ketonic and enolic modifications. Magnesium phenyl bromide reacts with ethyl hydroxymethylenemalonate to form a product, which, when decomposed in the usual way, yields ethyl benzylidenemalonate. Magnesium ethyl bromide also reacts with ethyl hydroxymethylenemalonate, but the product could not be identified.

Ethyl α-phenylpropylmalonate, $\text{CHPhEt}\cdot\text{CH}(\text{CO}_2\text{Et})_2$, b. p. 187–188°/22 mm., prepared by the action of magnesium ethyl bromide on ethyl benzylidenemalonate, is a colourless liquid; the corresponding acid, m. p. 74°, crystallises with $1\text{H}_2\text{O}$.

Magnesium phenyl bromide reacts with phenyl formylethyl ketone to form a product which yields benzylidenepropiophenone. With magnesium ethyl bromide a substance was obtained consisting of impure phenyl α-methylbutenyl ketone, which was identified by means of its *dibromide*, m. p. 67°, and also by its conversion into phenyl β-phenyl-α-methylbutyl ketone by the action of magnesium phenyl bromide. *Phenyl β-phenyl-α-methylbutyl ketone*,
 $\text{CHPhEt}\cdot\text{CHMe}\cdot\text{COPh}$,

m. p. 60·5°, prepared by the action of magnesium ethyl bromide on benzylidenepropiophenone, forms white, slender needles; its *oxime* has m. p. 119°.

Ethyl ethoxymethylenemalonate reacts with magnesium phenyl bromide with formation of a product which yields ethyl diphenylmethylmalonate; on treating this ester with alcoholic potassium hydroxide, *potassium ethyl diphenylmethylmalonate* is obtained. When ethyl ethoxymethylenemalonate is treated with magnesium ethyl bromide, *ethyl α-ethylpropylmalonate*, $\text{CHEt}_2\cdot\text{CH}(\text{CO}_2\text{Et})_2$, b. p. 138°/21 mm., is obtained as a colourless, mobile liquid.

β-Ethoxypropiophenone reacts with magnesium phenyl bromide with formation of *diphenylethoxyethylcarbinol*,

h. p. 207°/21 mm., m. p. 78°, which crystallises in white plates. This ketone also reacts with magnesium ethyl bromide with production of *phenylethylethoxyethylcarbinol*, $\text{OEt}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CPhEt}\cdot\text{OH}$, b. p. 151°/24 mm., as a colourless, mobile liquid.

Phenyl β-ethoxystyryl ketone can be obtained in fair yield by boiling phenyl dibromostyryl ketone with sodium ethoxide. This ketone reacts with magnesium ethyl bromide in presence of the usual quantity of ether to form a product, which, when decomposed with hydrochloric acid at 0°, yielded ethoxydiphenylethylalyl alcohol, together with ethoxyphenylethylpropiophenone and two solid compounds, $\text{C}_{34}\text{H}_{32}\text{O}_3$, one of which has m. p. 205° and forms white needles, whilst the other has m. p. 185° and forms yellow needles; the white substance slowly changes in solution into the yellow compound. *Ethoxydiphenylethylalyl alcohol*,

m. p. 60·5°, crystallises in white, slender needles. *Ethoxyphenylethylpropiophenone*, $\text{OEt}\cdot\text{CPhEt}\cdot\text{CH}_2\cdot\text{COPh}$, b. p. 96°/18 mm., is a colourless, mobile liquid; its *semicarbazide-semicarbazone* has m. p. 161°. In another experiment on the action of magnesium ethyl bromide on phenyl β-ethoxystyryl ketone, a much larger quantity of ether was used, and, on decomposing the product, the same three solid compounds were obtained, together with *γ-diphenyl-Δ^{8,8}-heptadiene*, $\text{CPhEt}\cdot\text{CH}\cdot\text{CPh}\cdot\text{CHMe}$, b. p. 191–195°/20 mm., as a colourless liquid. When phenyl β-ethoxystyryl ketone is added to magnesium phenyl bromide in presence of a large quantity of ether, and the product is decomposed in the usual way, tetraphenylalyl alcohol is

obtained, but if the reaction is carried out in presence of only the usual quantity of ether, *ethoxytriphenylallyl alcohol*,

m. p. 120.5° , is produced, which crystallises in white, slender needles.

These experiments with phenyl β -ethoxystyryl ketone show that in the reaction between organic magnesium compounds and unsaturated compounds having an alkyloxy-group in the β -position, either $\alpha\beta$ - or $\alpha\delta$ -addition takes place, and the alkyloxy-group of the resulting substance may or may not be replaced subsequently by a hydrocarbon residue. It is also shown that the influence of the β -ethoxy-group on the mode of addition is approximately the same as that of the phenyl group.

E. G.

Action of Light on Unsaturated Ketones in Presence of Uranyl Salts. PAUL PRÄTORIUS and FRANZ KORN (*Ber.*, 1910, 43, 2744—2746).—Distyryl ketone, when exposed to the action of light in presence of uranyl chloride in acetic acid suspension, yields a colourless compound, $(\text{C}_{17}\text{H}_{14}\text{O})_2$, m. p. 245° (decomp.), crystallising in needles. On oxidation with chromic acid, α -truxillic acid, benzoic acid, and carbon dioxide are formed. Accordingly, the formula

is assigned to the bimolecular compound.

A by-product is a substance soluble in acetic acid, which crystallises in colourless needles, m. p. 183° .

The red di-*p*-methoxydistyryl ketone uranyl chloride is stable towards light.

Dibenzylidenecyclopentanone uranyl chloride is decomposed to a colourless compound, crystallising in pointed prisms, m. p. 248° , which gives an orange-yellow coloration with concentrated sulphuric acid.

E. F. A.

Existence of 2:2'-Dinitrobenzoin. THOR EKECRANTZ and ALFR. AHLQVIST (*Ber.*, 1910, 43, 2606—2609. Compare Abstr., 1908, i, 347; Popovici, Abstr., 1907, i, 628).—A modification of Popovici's method (Abstr., 1908, i, 550) for the preparation of the so-called 2:2'-dinitrobenzoin is described, and the yield is increased to 0.4 gram from 25 grams of aldehyde. The product melts at 168 — 169° (corr.), not 161 — 162° , contains two atoms of hydrogen more than the benzoin, and is not oxidised to any appreciable extent by chromic acid mixture.

J. J. S.

Colour and Affinity for Mordants of Anthraquinone Derivatives. II. GUSTAV HELLER (*Ber.*, 1910, 43, 2890—2892. Compare Abstr., 1908, i, 995).—According to previous workers, the salts of anthraquinone-2:3-dicarboxylic acid, as well as those of the 1:3- and 1:4-acids, are reddish (compare Elbs and Euriich, Abstr., 1890, i, 511). Since this does not agree with the view put forward in the former paper, the author has prepared these substances, and finds that their alkaline solutions are colourless when pure. Nevertheless, they are fixed to a certain extent by some metallic hydroxides.

[With ERICH GRÜNTAL.]—*o*-Xyloyl-*o*-benzoic acid, prepared by the Friedel and Crafts' reaction according to the method previously described (Abstr., 1908, i, 994), has m. p. 167° (F. Meyer, Abstr., 1882, 848, gave 161.5°).

2:3-Dimethylanthraquinone has m. p. $205-206^{\circ}$ (Elbs and Eulich gave 183° ; Limpricht, Abstr., 1900, i, 599, gave 200°).

1:4-Dimethylanthraquinone has m. p. $140-141^{\circ}$ (Elbs and Eulich gave $118-119^{\circ}$).

R. V. S.

Chrysophanic Acid. OTTO A. OESTERLE and U. JOHANN (*Arch. Pharm.*, 1910, 248, 492-500).—The dimethyl ether, obtained together with a little monomethyl ether by treating chrysophanic acid with methyl sulphate, is partly demethylated by concentrated sulphuric acid on the water-bath or by aluminium chloride at 115° , yielding only one methyl ether, identical with the above. Consequently the hydroxyl groups in chrysophanic acid are not methylated with equal ease; the one which is easily methylated occupies probably a β -position, the other an α -position. Ethyl chloroacetate is a reagent which readily attacks hydroxyl groups in the α -position (D.R.P. 158277); its action on chrysophanic acid, however, does not lead to definite results; the authors claim from them, however, that one hydroxyl group is probably in a β -position.

Chrysophanic acid methyl ether and aqueous ammonia, at 140° , yield a substance, $C_{16}H_{13}O_2N, \frac{1}{2}H_2O$, m. p. $237-239^{\circ}$, which crystallises in brownish-red needles, and has the composition of an amino-chrysophanic acid methyl ether; it is converted by nitrous acid into chrysophanic acid methyl ether, a reaction which is explained, in accordance with Scholl and Parthey's results (Abstr., 1906, i, 439), by ascribing to the substance

the annexed constitution, assuming that the hydroxyl groups in chrysophanic acid are in positions 1 and 6 and the methyl group in position 2.

C. S.

So-called Methylchrysophanic Acid. OTTO A. OESTERLE and U. JOHANN (*Arch. Pharm.*, 1910, 248, 476-491).—Chrysophanic acid, when prepared from rhubarb or chrysarobin, is accompanied by a substance containing methoxyl, which is stated by Hesse to be methylchrysophanic acid (Abstr., 1900, i, 41). Gilson claims that in the case of chrysophanic acid from rhubarb the accompanying substance is rheochrysidin (*Arch. internat. Pharm. Thér.*, 1905, 14, 492). The authors show, however, that in chrysophanic acid from both sources the accompanying substance is the methyl ether of frangula-emodin. Chrysophanic acid, obtained by the oxidation of chrysarobin in alkaline solution, is methylated in the manner described previously (Abstr., 1905, i, 911), and the yellow substance, m. p. 224° , accompanying the dimethyl ether is separated therefrom by dilute alcohol; it has after repeated recrystallisation m. p. $226-227^{\circ}$ and the composition of a trimethoxymethylanthraquinone. It can be demethylated by aluminium chloride at 115° , or, better, by concentrated sulphuric acid at 160° ,

yielding a substance, m. p. 256—257°, identical with frangula-emodin (Abstr., 1908, i, 350), the identity being confirmed by a comparison of the *triacetates*, $C_{14}H_4O_3Me(OAc)_3$, yellow needles, m. p. 197—198°. Hence, the substance accompanying chrysophanic acid, obtained from chrysarobin, is a methyl ether of emodin. It can be isolated, although with considerable difficulty, by extracting the acetylated acid with alcohol at 50—55°; the acetate of emodin methyl ether thus obtained has m. p. 181—183°, but it still contains a little acetate of chrysophanic acid, because after hydrolysis, recrystallisation of the hydrolysed product, and re-acetylation, the m. p. is 190—191.5°. The hydrolysis of the acetate by aqueous potassium hydroxide yields an *emodin methyl ether*, $C_{14}H_4O_3Me(OH)_2 \cdot OMe$, orange-red needles, m. p. 206—207°, identical with that obtained by the partial demethylation of frangula-emodin trimethyl ether by aluminium chloride at 115° for three-quarters of an hour. The ether dissolves in dilute alkali hydroxides with an intense red colour, and forms a *dipropionate*, m. p. 162—164°. It is shown to be identical with Gilson's rheochrysidin by its crystallographic properties, and with Hesse's physcion (lichen-chrysophanic acid) (Abstr., 1906, i, 280) by a comparison of the *dibenzoylates*, m. p. 230°, and of the products of reduction by zinc and acetic acid. C. S.

Some Derivatives of Acenaphthenequinone. M. ZSUFFA (*Ber.*, 1910, 43, 2915—2922).—Naphthalic anhydride does not enter into the Friedel and Crafts' reaction with aromatic hydrocarbons, so that the carbonyl groups in the 1:8-position behave differently from those in the 1:2-position, as in phthalic anhydride. Acenaphthenequinone,

$(C_{10}H_6) \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix}$, however, readily undergoes this and other condensations.

With aromatic hydrocarbons or with chlorobenzene, diaryl derivatives of the type $C_{10}H_6 \begin{smallmatrix} \diagup CAr_2 \\ \diagdown CO \end{smallmatrix}$ are produced, and these are even more

readily obtained from dichloroacenaphthenone, $C_{10}H_6 \begin{smallmatrix} \diagup CCl_2 \\ \diagdown CO \end{smallmatrix}$. Acenaphthenequinone also condenses in a similar manner with dimethylaniline in the presence of zinc chloride or of concentrated hydrochloric acid, and with phenols (resorcinol) in presence of zinc chloride or tin chloride. From 9:9-diphenylacenaphthenone, diphenyl- α -naphthylmethane can be prepared with good yield, whilst from 9:9-tetramethyldiaminodiphenylacenaphthenone the corresponding hydrocarbon can also be prepared. The latter is readily oxidised to the naphthyl analogue of malachite-green.

9:9-Diphenylacenaphthenone (Beschke, Abstr., 1909, i, 918) can be obtained from acenaphthenequinone, or, better (yield almost quantitative), from dichloroacenaphthenone. In the latter case the action is vigorous, and should be moderated by the use of a solvent (carbon disulphide). When the substance is heated with alcoholic potassium hydroxide for four hours on the water-bath, 8-diphenylmethyl-1-naphthoic acid, $C_{24}H_{16}O_2$, crystallising in small, colourless laminae, m. p. 227°, is obtained. On distillation in a vacuum with two and a-half times its weight of barium hydroxide, this yields diphenyl- α -naphthylmethane,

$C_{10}H_7 \cdot CHPh_2$, which forms colourless needles, m. p. 150° . 8-Diphenylmethyl-1-naphthoic acid, when oxidised with chromic acid, gives *diphenylnaphthalide*, $C_{10}H_6 \begin{smallmatrix} \diagup CPh_2 \\ \diagdown CO \end{smallmatrix} O$, which crystallises in colourless needles, m. p. 204° .

9:9-Dichlorodiphenylacenaphthenone, $C_{24}H_{11}OCl_2$ (from dichloroacenaphthenone and chlorobenzene), forms small, colourless needles, m. p. 151° . 8-Dichlorodiphenylmethyl-1-naphthoic acid, $C_{24}H_{10}O_2Cl_2$, crystallises in small, colourless laminae, m. p. $224-225^\circ$.

9:9-Tetramethyldiaminodiphenylacenaphthenone, $C_{28}H_{28}ON_2$, is prepared by heating acenaphthenequinone with dimethylaniline and a small quantity of concentrated hydrochloric acid to 150° for three hours. It forms small, yellow laminae or needles, m. p. $204-205^\circ$. Its solution in glacial acetic acid is coloured malachite-green by oxidising agents, but the coloration disappears on dilution with water. Prolonged boiling with alcoholic potassium hydroxide leaves the compound unaffected. The hydrochloride, $C_{28}H_{28}ON_2 \cdot 2HCl$, prepared with hydrogen chloride in benzene solution, forms colourless needles, which with water regenerate the base. The picrate,

$C_{28}H_{28}ON_2 \cdot 2C_6H_3O_7N_3$, forms lemon-yellow crystals. The dimethiodide, $C_{28}H_{28}ON_2 \cdot 2MeI$, has m. p. $224-225^\circ$ (decomp.). When 9:9-tetramethyldiaminodiphenylacenaphthenone is boiled for four hours with amyl-alcoholic potassium hydroxide, 8-tetramethyldiaminodiphenylmethyl-1-naphthoic acid, $C_{28}H_{28}O_2N_2$, is obtained. It crystallises in pale yellow needles, m. p. $260-262^\circ$, and is soluble in acids and alkalis. The barium salt is sparingly soluble in water. Distillation of the acid with barium hydroxide yields tetramethyldiaminodiphenyl- α -naphthylmethane, $C_{10}H_7 \cdot CH(C_6H_4 \cdot NMe_2)_2$, which forms yellow needles, m. p. $161-162^\circ$, and on oxidation gives naphthyl-malachite-green.

Anhydrosorcinolacenaphthenone, $C_{10}H_6 \begin{smallmatrix} \diagup C \\ \diagdown CO \end{smallmatrix} \begin{smallmatrix} C_6H_3 \cdot OH \\ C_6H_3 \cdot OH \end{smallmatrix} O$, is prepared by heating acenaphthenequinone with resorcinol and zinc chloride for two hours at 180° . It is a pale brown, amorphous powder, which is soluble in alkali hydroxides, giving a yellowish-red coloration and a green fluorescence. R. V. S.

Derivatives of the Dextro-Antipode of Natural l-Menthol. LEO A. TSCHUGAEFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 714-718. Compare Skwortzoff, *ibid.*, 1910, 42, 55).—The oil of Bucco leaves, freed from diosphenol by repeated treatment with 20% alkali hydroxide, was dried and fractionated. The fraction boiling at $190-225^\circ$ was reduced with sodium and alcohol, the product distilled in steam, and the distillate then extracted with ether, dried, and redistilled. The fraction boiling at $200-220^\circ$, containing most of the menthol, was then converted into sodium methylxanthate, which, by the action of iodine, was converted to the disulphide, thus:

$C_{15}H_{19}O \cdot CS_2Na + 2I = S_2(CS \cdot O \cdot C_{15}H_{19})_2 + 2NaI$,
m. p. $92-92.5^\circ$, $[a]_D + 183.4^\circ$, $[a]_D + 226.3^\circ$.

The latter with potassium cyanide gave the anhydride, $(C_{15}H_{19}O \cdot CS)_2S$, m. p. $147.5-148^\circ$, forming yellowish-green, hexagonal crystals.

In toluene solution at 20° it gave $[\alpha]_D +46.42^\circ$, $+46.50^\circ$, $[\alpha]_x +21.17^\circ$, the corresponding *l*-menthylxanthic anhydride giving $[\alpha]_D -46.50^\circ$, $[\alpha]_x -21.30^\circ$. The new compound must therefore be a derivative of *d*-menthol, and the two substances are optical antipodes. The disulphide of *l*-menthol has $[\alpha]_D -182.8^\circ$, $[\alpha]_x -225.1^\circ$. By saponification the *d*-menthylxanthic anhydride yields a menthol, m. p. 42°. Z. K.

Constitution of Fenchone. V. and VI. LOUIS BOUYEAULT and F. LEVALLOIS (*Bull. Soc. chim.*, 1910, [iv], 7, 963—968, 968—973).—These two papers are in continuation of work published previously (this vol., i, 686), and record results given already in part (*Abstr.*, 1909, i, 497, 595). Fuller experimental details and an outline of the principles underlying the syntheses effected are now given.

The following results are new. *apofenchene* hydrochloride (*Abstr.*, 1908, i, 193), treated in succession with magnesium ethyl bromide and carbon dioxide, furnishes an acid having the same boiling point as dihydrofencholenic acid, but yielding an anhydride having b. p. 92.2/20 mm., which is 3° lower than that of the expected anhydride (this vol., i, 573), and an amide, having m. p. 104°, as against 108° for dihydrofencholenamide, although it forms nacreous leaflets in all respects similar to those formed by the latter. T. A. H.

Action of Magnesium on a Mixture of Allyl Bromide and Pulegone (Synthesis of 1-Methyl-3-allyl-4-isopropylidenecyclohexan-3-ol). G. G. von FERSEN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 681—683).—1-Methyl-3-allyl-4-isopropylidenecyclohexan-3-ol,

obtained when magnesium is treated with a small quantity of allyl bromide and a mixture of pulgone and allyl bromide then added drop by drop, has b. p. 135—135.5°/27 mm., $D_4^{25} 0.9264$, $n_D^{20} 1.49039$; it is a colourless liquid with a pleasant odour, which on oxidation with permanganate yields a complex mixture of acid and neutral products. Z. K.

Action of Hydroxylamine on Nitrosochlorides and Nitrosates. II. α -Pinene-*o*-hydroxylamineoxime. GUIDO CUSMANO (*Gazzetta*, 1910, 40, ii, 122—131. Compare this vol., i, 685).—From α -pinene bisnitrosochloride, the author has prepared α -pinene-*o*-hydroxylamineoxime similarly to the *d*-limonene-*o*-hydroxylamineoxime previously described (*loc. cit.*), but he has found that the compound reacts like the ordinary *m*-hydroxylamineoximes, so that the anomalous behaviour of the *d*-limonene derivative still requires explanation.

α -Pinene-*o*-hydroxylamineoxime forms lustrous needles, which decompose about 140°. It reduces Fehling's solution in the cold, and is soluble in alkalis, whilst with acids it yields monobasic salts. The hydrochloride, $\text{C}_{10}\text{H}_{18}\text{O}_2\text{N}_2 \cdot \text{HCl}$, which is formed in addition to the free base in the preparation of the substance, crystallises in tufts of silky needles, m. p. about 170°; when the solvent contains water, it

crystallises in hexagonal laminae with H_2O , and these sinter at about 100° , decomposing at 165° . The *sulphate*, $\text{C}_{10}\text{H}_{18}\text{O}_2\text{N}_2\cdot\text{H}_2\text{SO}_4$, forms four-sided tablets. By the action of nitrous acid on either of these salts, the *isonitroamineoxime* is formed (compare this vol., i, 574). The hydroxylamine group of the hydroxylamineoxime reacts with aldehydes. The *pentylidene* derivative,

forms flat, quadrangular crystals, m. p. 150° . The *benzylidene* derivative, $\text{OH}\cdot\text{N}\cdot\text{C}_{10}\text{H}_{15}\cdot\text{N}\begin{array}{c} \text{CHPh} \\ \diagup \quad \diagdown \\ \text{O} \end{array}$, crystallises in hexagonal laminae, m. p. 167° . The *p-nitrobenzylidene* compound, $\text{C}_{17}\text{H}_{21}\text{O}_4\text{N}_2\cdot\text{C}_6\text{H}_5\text{O}$, forms yellow crystals, m. p. $163\text{--}165^\circ$.

Pinene-*o*-hydroxylamineoxime is decomposed by very dilute oxalic acid, with formation of carboxime and hydroxydihydrocarboxime, so that instead of the elimination of the oxamic grouping, the destruction of the piceanic ring is effected. These two substances are formed in all the reactions in which the hydroxylamineoxime reacts in an acid medium, and hence they occur as by-products in its preparation. By the action of alkalis, the hydroxylamineoxime in time loses the oxamic group, hydroxylamine and nitrosopinene being formed.

o-Nitrosoisnitrosopinene, $\text{C}_{10}\text{H}_{15}\begin{array}{c} \text{NO} \\ \diagup \quad \diagdown \\ \text{N}\cdot\text{OH} \end{array}$, may be obtained by oxidis-

ing α -pinene-*o*-hydroxylamineoxime, preferably by dissolving it in dilute sulphuric acid and adding the calculated quantity of potassium dichromate, the dilute solutions being kept cool with ice. It is a crystalline substance, which explodes at about 60° , and readily oxidises in the air, absorbing one atom of oxygen, with production of a yellow substance. When a solution of the hydroxylamineoxime hydrochloride is treated with iron alum, a substance is obtained containing 51% of iron; it is orange-yellow in colour, and decomposes at $110\text{--}120^\circ$.

R. V. S.

[Essential Oils.] HEINRICH HAENSEL (*Berichte von H. Haensel*, April to September 1910, 6—53).—The flowers of *Gnaphalium avicularium*, used as an insectifuge, yielded 0.04% of dirty green, aromatic oil, which solidified at 4° and had D_{20}^{20} 0.921. After treatment with animal charcoal, it was bluish-green in colour, solidified at 7° , had acid number 14.45, ester number 9, and was incompletely soluble in 95% alcohol. The insoluble matter consisted of stearopten, m. p. $48\text{--}50^\circ$, containing a bluish-green colouring matter. The soluble portion of the oil contained (1) an *acid*, m. p. $34\text{--}36^\circ$, with an odour recalling that of hexoic acid, (2) *p*-cresol, and (3) an alcohol having a fruity odour.

Syrian peppermint oil (compare this vol., i, 401) gave a terpeneless fraction having the following constants: acid number 1.87, ester number 22.4, acetyl ester number 180 (one hour), corresponding with 6.24% ester menthol and 51.73% free menthol. The crude oil yielded 5% of terpene, having D_{20}^{20} 0.8880.

Datura Stramonium leaves yielded 0.045% of a volatile oil of dark brown colour and tobacco-like odour. It had D_{20}^{20} 0.9440, solidified at 20° , and after treatment with animal charcoal showed acid number

52.4, and ester number 9.57. The saponified oil contained a minute quantity of an alcohol having a strong odour of tobacco. The aqueous distillate was alkaline and of blue colour, but became colourless on addition of acid, regaining the blue colour on addition of alkali.

Dalmatian yellow sunflowers (*Sonnengoldblumen*) furnished 0.235% of oil, D_{20}^{25} 0.9100, n_D^{20} 1.4510, of greenish-yellow colour and pleasant, sweet aroma. It had acid number 8.9 and ester number 87.66, corresponding with 24.12% of alcohol, $C_{16}H_{18}O$. T. A. H.

Spearmint Oil. F. ELZE (*Chem. Zeit.*, 1910, 34, 1175).—The carvone-free residue of spearmint oil has an intense spearmint odour, and on distillation under reduced pressure gives the following fractions: b. p. 40–45°/4 mm., 15%, containing 2.8% esters; b. p. 45–75°/4 mm., 15%; b. p. 75–80°/4 mm., 24%, containing 19% esters; b. p. 80–85°/4 mm., 7.5%; and 85–100°/4 mm., 35.0%, containing 31% esters. From the first of these fractions phellandrene was isolated. The last fraction, freed from aldehydes and phenols, furnished on hydrolysis acetic and valeric acids and dihydrocuminyl alcohol. Dihydrocuminyl acetate has the characteristic odour of spearmint oil. T. A. H.

Cold Vulcanisation of Caoutchouc. B. B. BYSOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 638–647).—A criticism of Weber's theory of the vulcanisation of caoutchouc with sulphur chloride, S_2Cl_2 . The chemical explanation of the process is not satisfactory. Regarding caoutchouc as a heterogeneous disperse system consisting of two liquid phases, it will probably have the general properties of a colloid, such, for instance, as the property of adsorption. The change in caoutchouc on vulcanisation with sulphur chloride is due to the adsorption of the latter, the process of vulcanisation is thus physical not chemical. The connexion between the amount of sulphur contained in the caoutchouc after vulcanisation and the concentration of the benzene solutions of sulphur chloride employed has been studied, and the resulting curve, which is hyperbolic, is drawn. Z. K.

Chlorophyll Group. VIII. Formation of Phyllotaonin from Chlorophyllan. HENRY K. MALARSKI and LEON MARCHLEWSKI (*Biochem. Zeitsch.*, 1910, 28, 48–52. Compare this vol., i, 692).—When chlorophyllan (15 grams), obtained from stinging nettles, is left for twenty-four hours with 200 c.c. of methyl-alcoholic potassium hydroxide solution, hydrolysis takes place. The mass is poured into 2 litres of water, and the phytol removed by extraction with ether; acetic acid is added, and the ether extraction repeated. The ethereal solution is fractionated by extracting with gradually increasing amounts of hydrochloric acid, namely, from 1 to 20%. The product, soluble in 1% hydrochloric acid, contains chlorophyllanic acid, and the solution in 18% hydrochloric acid gives all the characteristic absorption bands of allophyllotaonin (Kózniewski and Marchlewski, *Abstr.*, 1907, i, 867), and when treated with alkalis gives the absorption bands of phyllotaonin. J. J. S.

Commercial Azolitmin. PAUL SCHEITZ (*Zeit. anal. Chem.*, 1910, 49, 735–736. Compare following abstract).—Azolitmin occurs in commerce in the form of bluish-black scales, contains very little

mineral matter, dissolves in water with a red coloration, but becomes insoluble in water after heating at 100° during three to four hours. It dissolves in ammonia or alkali solutions, forming blue liquids, but is not re-precipitated therefrom by acids, the solutions merely changing colour to red. The substance appears to be an ammonium salt, since it evolves about 8.5% of ammonia on treatment with alkalis.

By dissolving commercial azolitmin in ammonia solution, recovering the colouring matter by adding excess of hydrochloric acid and warming, and then purifying the precipitated product by boiling with alcohol, about 22% of a nitrogenous substance closely resembling the azolitmin of litmus is obtained. This is greenish-black in colour, and almost insoluble in water, alcohol, or acetone; it absorbs ammonia gas, forming a bluish-black product, which dissolves in water, forming a red solution from which the purified azolitmin is regenerated on addition of excess of acid or salts of heavy metals. This ammonium compound is a useful indicator. Similar products are obtained with methylamine and dimethylamine.

T. A. H.

The Portion of Litmus Soluble in Alcohol. PAUL SCHRETZ (*Zeit. anal. Chem.*, 1910, 49, 736—739. Compare preceding abstract).

—The isolation of a blue colouring matter distinct from azolitmin and soluble in alcohol is described. When crude litmus is treated with dilute hydrochloric acid until no more carbon dioxide is evolved, the red solution formed slowly deposits, when warmed at 100°, a dark brown precipitate, which, when boiled with water, separates into (a) a finely-divided reddish powder, containing some azolitmin, but consisting chiefly of products soluble in alcohol, and (b) a grey-steel product, mainly composed of azolitmin, but containing a little alcohol-soluble matter.

When boiled with a mixture of alcohol (2 parts) and water (1 part), preparations a and b furnish (1) azolitmin, insoluble in aqueous alcohol, and (2) a mixture of Kane's erythrolein and erythrolitmin with a third substance, which is bright brown in colour, all of these being soluble in hot aqueous alcohol. Of these three substances the first two can be eliminated by extraction with hot acetone, leaving the third in an impure form, from which a purer form can be prepared by dissolving it in hot aqueous alcohol, filtering, and cooling, when it is deposited as bright brown powder, equivalent in weight to 1.5% of the purified litmus. This is soluble in formic acid, pyridine, or ammonia, forming a bluish-violet solution with the last-mentioned solvent. It absorbs ammonia gas, becoming hot, and forming a dark blue ammonia compound, which dissolves in water to a reddish solution. This ammonia compound is a more delicate indicator than the corresponding derivative of azolitmin (compare preceding abstract). Similar substances are formed by absorption of methylamine and dimethylamine. T. A. H.

Phycocerythrin and Phycocyanin from *Ceramium rubrum* (Huds.). HARALD KYLIN (*Zeitsch. physiol. Chem.*, 1910, 69, 169—239. Compare Hanson, *Proc.*, 1909, 25, 117; Molisch, *Abstr.*, 1895, i, 556; 1906, ii, 118; Gaidukov, *ibid.*, 1904, i, 439).—Details are given for the preparation of solutions of pure phycocerythrin and phycocyanin from *Ceramium rubrum*. The isolation is based on the

fact that both colouring matters can be obtained in a crystalline form by the addition of the requisite amount of ammonium sulphate to their solutions; the phycoerythrin is deposited when 18 grams of sulphate, and the phycocyanin when 25 grams of sulphate, have been added to 100 c.c. of the solution. Magnesium sulphate may also be used, but larger quantities are necessary. Phycocyanin can be precipitated in an amorphous state by completely saturating its solution with sodium chloride, but phycoerythrin is not precipitated under these conditions.

The phycoerythrin solution has a carmin-red colour, and when dilute a tinge of violet; concentrated solutions have an orange colour, and all solutions give a characteristic orange-yellow fluorescence. It gives all the characteristic reactions of a protein, including the biuret reaction (compare Hanson). The colouring matter dissolves in water containing a small amount of alkali or of neutral salts, but is deposited in a crystalline form when all salts are removed by dialysis. It is insoluble in ordinary organic solvents, but dissolves in dilute acetic acid and also in extremely dilute hydrochloric acid, yielding solutions which do not fluoresce.

The conclusion is drawn that the acid decomposes the phycoerythrin into protein and colouring matter, and that the precipitate obtained on adding a small amount of sodium carbonate to the acid solution is the colour-constituent. The addition of a trace of acid to the ordinary solution precipitates the phycoerythrin.

The small amounts of salts which are necessary to keep the colouring matter in solution are sufficient to cause complete precipitation when the solution is heated at 90° . The addition of traces of acid reduce the temperature of coagulation, and the amount of acetic acid necessary to give the ordinary protein reaction produces coagulation at $53-55^{\circ}$. The addition of a trace of alkali prevents coagulation.

The action of pepsin and trypsin is represented as first causing a decomposition of the phycoerythrin into protein and colour-constituents, and then the decomposition of the protein. After the digestion with pepsin, the colour-constituent can be removed by shaking with amyl alcohol. The results of analyses of phycoerythrin gave: C=50.82, H=7.01, N=15.37, S=1.60, and O=25.20%.

The absorption spectrum of pure phycoerythrin contains three characteristic bands, two between *D* and *E*, and one between *E* and *F*. These bands have their maxima at $\lambda=569-565$, $541-537$, and $498-492 \mu\mu$. On dilution the second band disappears before the third.

Phycocyanin crystallises in rhombic plates, quite different from the crystals described by Molisch. It gives the protein reactions; its solubility in water, saline solutions, and dilute alkalis is similar to that to phycoerythrin, as is also its behaviour towards acids, pepsin, and trypsin.

A solution of phycocyanin containing the smallest possible amount of salt is completely coagulated when heated at 82° , and the addition of a little acetic acid reduces this to $46-48^{\circ}$.

The solutions of phycocyanin exhibit two absorption bands, one between *C* and *D* and the other between *D* and *E*, the maxima being at λ 618-613 and 553-549 $\mu\mu$.

J. J. S.

Sulphur Dyes. II. HERMANN WICHELHAUS (*Ber.*, 1910, 43, 2922—2926. Compare Abstr., 1907, i, 232; Erdmann and Schäfer, this vol., i, 718).—The distillate from 20 kilograms of cellulose (cotton) consisted of 5.7 litres of an aqueous liquid and 1 litre of an oily mass. From both of these only one phenol could be isolated, namely, phenol itself. The author has put forward the view that a sulphur dye could be formed from phenol, thus explaining the origin of sulphur dyes from cellulose. As an intermediate product, phenoxiquinone claims attention. Molecular-weight determinations in the case of the analogous toluquinone and thiotoluquinone confirm the original statement (*Ber.*, 1872, 5, 248) that phenoxiquinone has the formula $C_{18}H_{14}O_4$. When it is boiled with alkali sulphides and sulphur, or, better, heated with those substances under pressure at 200—220°, a sulphur dye is formed, which, after purification, contains C 75%, H 5%, S 12%. It is a dark brown powder, insoluble in alkaline carbonates, ammonia, and acids, but soluble in alkali sulphides. The last-named solution dyes cotton dark brown.

Phenoxiquinone also yields a dye free from sulphur when it is kept for ten days at the ordinary temperature in contact with sodium acetate and water. The crude product is purified by solution in sodium hydroxide, re-precipitation with acid, removal of phenol by means of steam, and final precipitation as iron salt, which is decomposed by hot hydrochloric acid. So obtained, the acid has m. p. 110°. When dissolved in sodium carbonate, it dyes cotton brown.

Fluorescein yields sulphur dyes when heated with sulphur or sulphur and sodium sulphide, but it is not possible to obtain them in a pure state. Dithiofluorescein chloride,

which is not a dye, condenses in presence of sulphuric acid or anhydride to form sulphur derivatives which are dyes. R. V. S.

Velocity of the Transformation of Oxonium Bases, Colour Bases, and Cyanides into Carbinol Bases and Leucocyanides. WOLF. J. MÜLLER (*Ber.*, 1910, 43, 2609—2613. Compare this vol., i, 407; Gerlinger, Abstr., 1904, i, 1040).—The velocity constants of various reactions studied by Hantzsch and his pupils (Abstr., 1900, i, 113, 256) have been recalculated from Hantzsch's data, and it is shown that, using the equation for a bimolecular reaction, quite concordant values for K are obtained.

Hantzsch's statement to the contrary is due to mistakes in calculation. J. J. S.

Stereochemistry of 1:4-Dimethyltetrahydrofuran and 1:4-Dimethylfuran. ANGEL DEL CAMPO Y CERDÁN (*Anal. Fis. Quim.*, 1910, 8, 227—244).—A geometrical study of the causes of the difference of stability of the two compounds (annexed formulae) from the point of view of the "tension" theory. It is shown that the mass of

the groups in the first compound causes a greater strain or deforma-

tion from the simple regular tetrahedral form, representing a carbon atom combined with four hydrogen atoms, than those of the second; the latter is therefore the more stable substance, as is actually the case.

W. A. D.

ω-Hydroxy-*s*-methylfurfuraldehyde. HENRY J. H. FENTON (*Ber.*, 1910, 43, 2795—2796. Compare Fenton and Gostling, *Trans.*, 1899, 75, 430; Fenton and Robinson, *ibid.*, 1909, 95, 1338; Alberda van Ekenstein and Blanksma; Erdmann, this vol., i, 762).—Attention is drawn to the fact that the hydroxyfurfuraldehydes prepared from the *ω*-bromomethylfurfuraldehyde and from inulin by the action of oxalic acid are identical. They yield the same phenylhydrazones and the same oxidation product, and both are to be regarded as *ω*-hydroxy-*s*-methylfurfuraldehyde.

J. J. S.

Triphenylmethyl. XIX. Quinocarbonium Salts. MOSES GOMBERG and LEE H. CONE (*Annalen*, 1910, 376, 183—238. Compare *Abstr.*, 1907, i, 504; 1909, i, 144; this vol., i, 55).—Not merely salts of triphenylmethane and xanthenol, but also those derived from diphenoxanthhydrol, dinaphthaxanthhydrol, thioxanthenol, and bromothioxanthenol exist in colourless benzenoid and yellow quinonoid forms. The acridol salts are also regarded as quinocarbonium salts. Diphenoxanthhydrol exists in the solid form as the colourless benzenoid carbinyl chloride, and appears to be incapable of yielding a stable coloured chloride hydrochloride; it can, however, be readily transformed by means of sulphur dioxide, sulphuric acid, or metallic halides. Dinaphthaxanthhydrol, on the other hand, yields a perfectly stable and intensely coloured chloride dichloride in addition to the colourless carbinol chloride.

Xanthhydryl chloride, $O \begin{smallmatrix} \text{C}_6\text{H}_4 \\ \diagup \quad \diagdown \\ \text{C}_6\text{H}_4 \end{smallmatrix} \text{CHCl}$ (compare Werner, *Abstr.*, 1902, i, 50), can be prepared by the action of hydrogen chloride on xanthhydrol in absolute ethereal solution. It is extremely sensitive to traces of moisture, but can be obtained in colourless needles, m. p. 73—75° after sintering at 71°. When further heated, hydrogen chloride is evolved, and at 170—175° the evolution is rapid. Hydrogen chloride is also evolved when the salt is heated with xylene or nitrobenzene, but whether dioxanthylene is formed or not has not been determined. It does not yield a stable quinonoid hydrochloride, but the following double salts have been prepared: *zincichloride*, $C_{13}H_9OCl_2ZnCl_2$, yellow, granular precipitate; *ferrichloride*,

m. p. 193° (compare Werner); *periodide*, $C_{13}H_9OCl_2I_3$, prepared from benzene solutions, dark blue crystals, m. p. 90°.

Xanthhydryl bromide, $O(C_6H_4)_2CHBr$, is much more stable than the chloride, and crystallises from light petroleum solutions in long, colourless needles, m. p. 88—90°, which turn yellow when kept. The pure quinocarbonium salt has not been obtained, but the following double salts are described: *zincibromide*,

slender, orange-yellow crystals; *periodide*, dark blue crystals with four or six atoms of iodine.

Xanthhydryl perchlorate, $C_{13}H_9O \cdot ClO_4$, forms dark red crystals, m. p. 208—209°.

Dinaphthaxanthen is best prepared by heating pure *p*-dihydroxynaphthylmethane (Manasse, Abstr., 1894, i, 577) with glacial acetic acid in a current of hydrogen chloride. Dinaphthaxanthhydryl can be prepared by Fosse's methods (Abstr., 1902, i, 171).

Dinaphthaquinoxanthhydryl chloride hydrochloride,

prepared by the action of acetyl chloride and hydrogen chloride on a benzene solution of the hydrol or on the anhydride in chloroform solution, crystallises in dark red needles, m. p. 228—229° (decomp.) and is extremely stable. When a current of air is passed through its toluene solution at 100°, hydrogen chloride is evolved, and *dinaphtha-*

xanthhydryl chloride, $O \begin{array}{c} C_{10}H_6 \\ C_{10}H_6 \end{array} \begin{array}{c} \text{CHCl} \\ \text{CHCl} \end{array}$, is precipitated on the

addition of light petroleum to the concentrated solution as slender, colourless needles, m. p. 205—206°, which are comparatively stable. The *zincchloride*, $C_{21}H_{13}OCl \cdot ZnCl_2$, forms a stable, orange-red, crystalline mass, and the *periodide*, $C_{21}H_{13}OCl \cdot I_2$, is precipitated when iodine is added to a benzene solution of the chloride. *Dinaphthaquinoxanthhydryl bromide hydrobromide*, $C_{21}H_{13}OBr \cdot HBr$, forms a red, crystalline mass, and is even more stable than the hydrochloride. The *perchlorate*, $C_{21}H_{13}O \cdot ClO_4$, forms red crystals with a golden reflex, is not molten at 260°, and is only slowly decomposed by water. Dinaphthaxanthen reacts with a carbon disulphide solution of bromine, yielding a red *dinaphthaxanthhydryl bromide perbromide* according to the equation: $O : (C_{10}H_6)_2 : CH_2 + 2Br_2 = O : (C_{10}H_6)_2 : CHBr \cdot Br_2 + HBr$, even when less than the theoretical amount of bromine is used. Chlorine reacts with a carbon tetrachloride solution of the xanthen, yielding an insoluble chloride perchloride.

Phenylthioxanthenol, prepared by a modification of Bünzly and Decker's method (Abstr., 1904, i, 912), reacts with a mixture of acetyl and hydrogen chlorides in chloroform solution, yielding *phenylquinoxanthioanthenyl chloride hydrochloride*,

the form of dark red crystals, the colour of which is much deeper than that of the corresponding oxygen compound. When dry air is led through a benzene solution of the red compound, hydrogen chloride is evolved and *phenylthioxanthenyl chloride*, $S \begin{array}{c} C_6H_4 \\ C_6H_4 \end{array} \begin{array}{c} S \\ S \end{array} PhCl$, is

formed. This crystallises from light petroleum in colourless prisms, m. p. 114—115°, after sintering at 110°, and turns red on exposure to the air. The chloride reacts with "molecular" silver in the presence of dry benzene, yielding a brownish-red, unsaturated compound, which is stable in the absence of air, but combines readily with oxygen, yielding the *peroxide*, $S : (C_6H_4)_2 : CPh \cdot O \cdot O \cdot CPh : (C_6H_4)_2 : S$.

which crystallises in colourless, hexagonal prisms, m. p. 187—188°, after sintering at 175—180°.

The 2-phenylthiol-4-bromobenzoic acid, $C_{13}H_9O_2SBr$, prepared by Goldberg's method (Abstr., 1905, i, 59), crystallises from glacial acetic acid, has m. p. 230—231°, and when warmed with concentrated sulphuric acid and then diluted yields 4-bromothioxanthone,

as slender, yellow needles, m. p. 165°, which reacts with phenyl magnesium bromide, yielding 4-bromo-9-phenylthioxanthanol,

as an oil, from which a few crystals, m. p. 75—80°, can be obtained. 4-Bromo-9-phenylquinothioxanthanyl bromide hydrobromide,

forms dark red needles, which are immediately decomposed by moisture. 4-Bromo-9-phenylthioxanthanyl bromide,

is usually slightly coloured, has m. p. 159°, after sintering at 150°, and after treatment with silver it does not yield a peroxide. In this respect it resembles the monohalogenated triphenylmethyl halides, as also in the readiness with which the two atoms of bromine are replaced by chlorine when the bromide is shaken with benzene and silver chloride.

4-Chloro-9-phenylquinothioxanthanyl chloride hydrochloride,

obtained by shaking the corresponding tribromo-derivative with benzene and silver chloride, or by saturating the benzene solution with hydrogen chloride, is somewhat paler in colour than the bromide, and gives up hydrogen chloride when dry air is passed through its benzene solution at the ordinary temperature. The product, 4-chloro-9-phenylthioxanthanyl chloride, $C_{19}H_{12}SCl_2$, is readily soluble in all solvents, and has not been obtained pure. 9-Phenylthioxanthanyl perchlorate, $C_{19}H_{11}S \cdot ClO_4$, crystallises in slender, dark red plates, m. p. 195—210°, after sintering at 150°, and thioxanthone perchlorate, $C_{13}H_9OS \cdot ClO_4$, in transparent, brown prisms.

A number of compounds of dimethylpyrone, benzo-γ-pyrone, anthone, aldehydes, ketones, and phenols with acids have been prepared. Many of them have been described previously (compare Collie and Tickle, Trans., 1899, 75, 710; Feist, Abstr., 1892, 811; Meyer and Villiger, Abstr., 1901, i, 658; Vorländer, Abstr., 1903, , 493; Werner, Abstr., 1902, i, 686; Ruhemann, Trans., 1900, 77, 85, 1123), but the following are new. Dimethylpyrone derivatives: $C_7H_4O_2 \cdot ZnCl_2$, colourless crystals, m. p. 200°; zincchloride, $C_7H_4O_2 \cdot HCl \cdot ZnCl_2$, colourless, hygroscopic crystals; $C_7H_4O_2 \cdot H_2Cl_2$, colourless crystals, m. p. 149°; mercuric chloride, $C_7H_4O_2 \cdot HCl \cdot HgCl_2$; irridchloride, $3C_7H_4O_2 \cdot 2FeCl_3$, lemon-yellow crystals, m. p. 173—174°; hydrobromide, $C_7H_4O_2 \cdot HBr$, m. p. 194—196°, after sintering at 188°; $C_7H_4O_2 \cdot ZnBr_2$, colourless crystals, m. p. 204—205°. Derivatives of

benzo- γ -pyrone: *hydrochloride*, $C_9H_6O_2.HCl$, m. p. $101-102^\circ$ (decomp); $C_9H_6O_2.ZnCl_2$, colourless crystals, m. p. $250-251^\circ$, after sintering at 205° ; *zincchloride*, $(C_9H_6O_2.HCl)_3.ZnCl_2$; $C_9H_6O_2.HgCl_2$, colourless crystals; *hydrobromide*, $C_9H_6O_2.HBr$, m. p. 175° , after sintering at 169° ; *hydrobromide periodide*, dark blue crystals.

The hydrochloride and hydrobromide of dimethylpyrone are decomposed when heated with benzene and a current of dry air drawn through the solution, and the salts of benzo- γ -pyrone are even less stable. Dimethylpyrone does not appear to react with phenyl magnesium bromide.

Although Perkin (Trans., 1896, 69, 1439) states that xanthone does not combine with acids, the following compounds have been prepared: *xanthone hydrochloride periodide*, prepared by passing hydrogen chloride into a carbon disulphide solution of xanthone and iodine; *xanthone hydrobromide*, $C_{13}H_8O_2.Br$, is unstable and forms pale yellow crystals; the *perbromide*, $C_{13}H_8O_2.HBr.Br_2$, forms orange-coloured crystals and gives up bromine readily; β -*phenonaphthaxanthone hydrobromide*, $C_{17}H_{10}O_2.HBr$, forms yellow needles; 5-methoxyxanthone *hydrobromide*, $C_{14}H_{10}O_3.HBr$, pale yellow crystals, and *xanthone stannichloride*, $(C_{13}H_8O_2)_2.SnCl_4$, pale yellow crystals, m. p. 245° .

These compounds are compared with the additive compounds formed by the union of carbonyl derivatives with acids and salts. In the latter group of additive compounds the acid, for example, hydrogen chloride, is, almost undoubtedly, added on to the carbonyl group, and it is suggested that probably the same type of reaction takes place with dimethylpyrone, xanthone, etc. The products are probably not salts, and their decomposition into oxygen compound plus acid is probably not a process of hydrolysis, but of dissociation (addenda-dissociation of Vorländer).

Fluorenone hydrobromide periodide, $C_{13}H_8O_2.HBr.I_2$, forms coloured crystals; *phenanthraquinone hydrobromide*, $C_{14}H_8O_2.HBr$, is unstable, and anthraquinone does not appear to yield a hydrobromide. Anisaldehyde hydrobromide (compare Vorländer) is stable, and can be prepared at the ordinary temperature. *p*-Hydroxybenzaldehyde, resorcyaldehyde, piperonal, vanillin, and β -naphtholaldehyde all yield comparative stable, yellow *hydrobromides*.

Phenols which can react in the tautomeric ketonic forms can also form hydrobromides, for example, orcinol, phloroglucinol, and quinol, whereas resorcinol, pyrogallol, guaiacol, and the methyl ethers of resorcinol, quinol, and pyrogallol do not combine with hydrogen bromide.

The application of the quinocarbonium theory to the cases of *pararos*aniline, phenylated rosanilines, amino-azines, aurin, phenolphthalein, fluorescein, and fluorone is discussed. The theory accounts for the fact that phenolphthalein is incapable of yielding a coloured hydrobromide, that fluorescein yields a mono-hydrobromide (Hewitt and Tervet, Trans., 1902, 81, 663), and dimethylfluoran a *dihydrobromide*, $C_{10}H_{10}O_2.2HBr$, slender, orange-yellow crystals. J. J. S.

Brominated and Iodinated Products of Curare Alkaloids
JÓZEF BURACZEWSKI and Z. ZBIEŃSKI (Bull. Acad. Sci. Cracov, 1910,
359-354) and two alkaloids, curine and tubocurarine, in commer-

cial tubocurare from the bamboo have been examined with regard to their behaviour towards bromine and iodine. Curine, in ethereal solution, gives with bromine a straw-yellow precipitate, probably of a dibromo-derivative, but does not yield a precipitate with iodine. An alcoholic solution, however, by treatment with iodine in carbon disulphide gives a brownish-red precipitate, which dissolves very easily in alkalis or in aqueous ammonia, being re-precipitated by acids in the form of an almost black substance containing 49.65% of iodine. Curine, therefore, resembles strychnine in its behaviour towards bromine, but not towards iodine. An alcoholic solution of tubocurarine and iodine in carbon disulphide give a similar precipitate of like properties. The formation of these iodinated products is of use in the examination of crude tubocurare, because the colour reactions of curine and tubocurarine are applicable only to the isolated alkaloids, not to crude tubocurare. C. S.

Action of Chlorine on Strychnine, Brucine, Cinchonine, Quinine, and Other Alkaloids. JÓZEF BURACZEWSKI and Z. ZATKIEWSKI (*Bull. Acad. Sci. Cracow*, 1910, 355—362).—On account of the oxidising action of chlorine, chlorinated derivatives of the alkaloids are more difficult to prepare than brominated or iodinated derivatives. By passing a slow current of dry chlorine over the well-cooled and shaken dry alkaloids, the authors find that chlorinated products are obtained containing usually more halogen than is the case in the usual methods of chlorination; heat is developed and frequently hydrogen chloride given off, although sometimes only after some time. By this process, strychnine absorbs five atoms of chlorine, brucine three, cinchonine four, cinchonidine three, quinine six, quinidine six, thebaine four, and morphine one. In these chlorinated alkaloids at least a part of the halogen is bound in the same way as the halogen in the brominated or iodinated derivatives, because all of the products except the chlorinated morphine yield with warm water an insoluble precipitate and a soluble salt of a chlorinated base. C. S.

Action of Acetone on Di-iodostychnine and on the Brominated Products of Strychnine and of Some Other Alkaloids. JÓZEF BURACZEWSKI and MIECISŁAS DZIURZYŃSKI (*Bull. Acad. Sci. Cracow*, 1910, 363—366).—Complicated reactions take place during the prolonged boiling necessary for the solution of di-iodostychnine (*Abstr.*, 1908, i, 1007) in acetone. Two colourless, non-poisonous, crystalline products are obtained, which do not exhibit the properties of strychnine or of its salts. Strychnine hydriodide and iodide, $C_{22}H_{22}O_2N_2I_2.HI$, are also produced, together with iodoacetone. Dibromostychnine and tetrabromostychnine (and also pentabromoquinine) likewise cause the formation of bromoacetone when they are boiled with acetone. The formation of these halogenated acetones is regarded as evidence that the method of union of the two iodine atoms in di-iodostychnine is the same as that of two bromine atoms in dibromo- or in tetrabromo-strychnine. C. S.

Oxidation Products of Brominated Strychnines. I. JOZEF BURACZEWSKI and T. NOWOSIELSKI (*Bull. Acad. Sci. Cracow*, 1910, 154—162).—On account of the scarcity of characteristic oxidation products of strychnine and of their importance for the determination of its constitution, the authors have commenced a more thorough examination of the precipitates obtained by Buraczewski and Dziurzyński (*Abstr.*, 1909, i, 672). These authors found that by warming dibromostrychnine with water a precipitate is formed; the bromostrychnine obtained from the filtrate yielded by bromination a mixture of tri- and tetra-bromostrychnines, which likewise yielded a precipitate when warmed with water. The basic substance obtained from the aqueous filtrate in the latter case has been brominated, yielding a product which again gives a precipitate when warmed with water. The first-mentioned precipitate dissolves almost completely in alcohol, but the others are separated by this solvent into a soluble and an insoluble portion. The insoluble portions behave alike towards alkalis, acids, and solvents, and are recrystallised, after being mixed, from hot acetic acid by the addition of water, yielding a substance, $C_{21}H_{20}O_4N_2Br_2$, which is dextrorotatory, non-poisonous, has no bitter taste, and is provisionally called *tribromostrychnine oxide*. The portions soluble in alcohol are combined and purified by precipitating the alcoholic solution with water containing hydrochloric acid; the product is amorphous (it has since been obtained crystalline in very small quantity), optically inactive, non-poisonous, and has a composition approximating to the formula $C_{21}H_{20}O_4N_2Br_2$. The aqueous filtrate, from which the last-mentioned precipitate has been separated, contains a substance which has pronounced basic properties, is levorotatory, and is non-poisonous, but has an intensely bitter taste. C. S.

Alkaloids in the Roots of *Sanguinaria canadensis* TAD. KŹNIEWSKI (*Bull. Acad. Sci. Cracow*, 1910, 235—246).—Sanguinarine, isolated by Dana in 1828 from the roots of *Sanguinaria canadensis*, and proved by Schiel in 1842 to be identical with chelerythrine obtained by Probst from *Chelidonium majus*, has been shown to be a mixture of three alkaloids by Schmidt and his collaborators, who found that the roots of *Sanguinaria* contain five alkaloids, namely, sanguinarine (red salts), chelerythrine (yellow salts), protopine, and β - and γ -homochelidonine (colourless salts). The last two are easily separated from the first three by their solubility in aqueous ammonia, but the separation of sanguinarine, chelerythrine, and protopine presents very great difficulties. The author describes a comparatively simple method which depends on the formation of sparingly soluble salts. The alcoholic extract of the powdered roots is evaporated, and the residue is treated with 5% and with 10% acetic acid. Three-quarters of the mass remains undissolved (*P*), and is worked for sanguinarine as described below. The acetic acid solutions are cooled and treated with 40% sulphuric acid, whereby a crystalline precipitate is formed, which is collected after forty-eight hours and yields pure chelerythrine after further purification. The filtrate is cooled in a freezing mixture, and just basified with ammonia. The resulting precipitate is extracted with hot dilute acetic acid, and the solution is

treated with an excess of 40% sulphuric acid. The yellow, crystalline precipitate obtained yields a further quantity of chelerithrine, whilst the filtrate by treatment with ammonia gives a violet precipitate. This is dissolved in 10% acetic acid, and the solution treated with an excess of sulphuric acid. A third precipitate is thus obtained containing a considerable quantity of chelerithrine and sanguinarine; the precipitate obtained by adding ammonia to the filtrate is dissolved in 10% sulphuric acid, and the solution is treated with more sulphuric acid, whereby a fourth crystalline precipitate containing chelerithrine and sanguinarine is obtained, the filtrate being worked for protopine, which is finally isolated in the form of its hydrochloride.

The residue (*P*) is ground with kieselguhr and heated for three hours with 20% sulphuric acid. The red solution deposits a scarlet precipitate on cooling, from which pure sanguinarine is obtained by further purification. The fact that the residue requires prolonged heating with sulphuric acid for solution is taken as evidence that sanguinarine is present in the roots in the form of a stable compound which yields the alkaloid by hydrolysis.

From his analyses the author concludes that sanguinarine separates from solutions containing alcohol in crystals containing $\text{Et}\cdot\text{OH}$; the m. p. of such crystals is 212° . Sanguinarine forms a *periodide*, $\text{C}_{25}\text{H}_{17}\text{O}_4\text{N}_2\text{HI}$, m. p. 205° , and chelerithrine, a *periodide*, $\text{C}_{21}\text{H}_{17}\text{O}_4\text{N}_2\text{HI}$,

m. p. 225° , crystallising in ruby-red needles.

Reactions of 2:4:6-Trihydroxypiperidine Trisulphite. JULIUS SCHENKEL (*Ber.*, 1910, 43, 2597—2601).—The additive compound of pyridine and sodium hydrogen sulphite, which is regarded as the trisulphite ester derived from 2:4:6-trihydroxypiperidine (compare Bucherer and Schenkel, *Abstr.*, 1908, i, 452), can be estimated by boiling with alkali hydroxide solution and titrating the ammonia evolved. It also reacts with a solution of *p*-nitrobenzenediazonium chloride in the presence of an excess of sodium hydrogen carbonate, yielding a blood-red solution, which changes to yellow on the addition of a slight excess of acid; in acid solution a voluminous, yellow precipitate is obtained, which decomposes rapidly, yielding a resinous product free from sulphur.

Benzoyl chloride and alkali react with the ester, yielding benzoic anhydride, and a hot solution of the ester rapidly transforms phenylhydrazine into its *N*-sulphonic acid.

When boiled with alkalis, the ester yields ammonia, alkali sulphite, and glutacetaldehyde, the last of which was isolated as its dianilide, $\text{NPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{NPh}$ (compare Zincke, *Abstr.*, 1904, i, 448; Koenig, *ibid.*, i, 817), the hydrochloride of which crystallises in red needles, m. p. $141\text{--}143^\circ$.

When the ester is neutralised with sodium hydroxide solution, and then boiled with phenylhydrazine for three hours, ammonia is evolved, and the sodium salt of 1-anilino-2:4:6-trihydroxypiperidine trisulphite, $\text{C}_{14}\text{H}_{12}\text{O}_4\text{N}_2\text{S}_3\text{Na}_3\cdot 2\text{H}_2\text{O}$, is obtained as colourless crystals, which begin to decompose at 180° .

The Action of Sulphites on Pyridine. FRITZ REITZENSTEIN and WILHELM BREUNING (*Ber.*, 1910, 43, 2939—2940. Compare Schenkel, preceding abstract).—A claim for priority. The existence of Zincke's glutacanaldehyde, which Schenkel has isolated in the form of its dianilide, had already been demonstrated by the authors, who obtained from it the ditoluidide (Brouning, *Diss.*, Würzburg, 1909).

Additive Compounds of Mercury Salts and Aromatic Bases. WILHELM STARONKA (*Bull. Acad. Sci. Cracov.*, 1910, 372—398).—The great solubility of mercury salts in organic bases is due to the formation of additive compounds of the salts and the solvent. The salts of mercury which have been examined are the cyanide, chloride, bromide, and iodide; the bases used are aniline, pyridine, and quinoline. Exactly weighed amounts of a salt and a base are heated in a sealed tube until fusion is complete. The tube is allowed to cool until crystals, generally of an additive compound, separate, and is then carefully re-heated until only a pair of crystals remain; the temperature at which the two crystals persist unchanged for a long time is taken as the temperature of solidification of the mixture under examination. The results are expressed graphically, the molecular concentrations of one constituent being plotted as abscissae, the corresponding temperatures of solidification as ordinates. The curves obtained are of two types, one kind exhibiting a maximum corresponding with the m. p. of the additive compound, and the other kind showing breaks, indicating the transition of one solid phase into another. The compositions of the additive compounds can be determined directly from curves of the first type. In the case of mixtures giving curves of the second type, it is necessary to isolate the solid phase before its composition can be determined by analysis. The isolation is a matter of some difficulty, because the solid phase is only stable within a definite range of temperature; a method is described by which the separation can be effected by the use of a centrifugaliser in an air-bath. Of the bases examined, pyridine shows the greatest tendency to form additive compounds; of the salts, the cyanide. The most frequently occurring types of additive compounds are $\text{HgX}_2 \cdot 2\text{B}$ and $\text{HgX}_2 \cdot \text{B}$, where $\text{B} = 1$ mol. of the base. The following now additive compounds have been obtained: $\text{Hg}(\text{CN})_2 \cdot 6\text{C}_5\text{NH}_5$; $\text{Hg}(\text{CN})_2 \cdot 3\text{C}_5\text{NH}_5$; $2\text{Hg}(\text{CN})_2 \cdot 3\text{C}_5\text{NH}_5$; $\text{Hg}(\text{CN})_2 \cdot \text{C}_5\text{NH}_5$; $\text{HgBr}_2 \cdot \text{C}_5\text{NH}_5$, m. p. 123° ; $3\text{HgBr}_2 \cdot 2\text{C}_5\text{NH}_5$, m. p. 134° ; $\text{HgI}_2 \cdot \text{C}_5\text{NH}_5$, m. p. 90° ; $\text{Hg}(\text{CN})_2 \cdot 3\text{C}_9\text{NH}_7$; $\text{HgBr}_2 \cdot 2\text{C}_9\text{NH}_7$; $\text{HgI}_2 \cdot 2\text{C}_9\text{NH}_7$; $\text{Hg}(\text{CN})_2 \cdot 4\text{PhNH}_2$ (metastable); $\text{HgBr}_2 \cdot \text{PhNH}_2$, m. p. 124° .

Theories of the Constitution of Double Salts. PAUL PFEIFFER [with B. FRIEDMANN and H. REKATE] (*Annalen*, 1910, 376, 310—344). The constitution of the double salts formed by metallic halogenides has been explained by various theories, of which the Blomstrand-Remsen and the Werner are the most prominent. According to the former, the constitution is represented by, for example,

$\text{Cl} \rangle \text{P} \langle \begin{smallmatrix} \text{Cl}:\text{Cl}:\text{Cl} \\ \text{Cl}:\text{Cl}:\text{Cl} \end{smallmatrix}$, the addition occurring by means of tervalent halogen atoms, whilst the constitution is expressed by $[\text{PtCl}_6]\text{K}_2$ by the well-known Werner theory.

The following compounds have been prepared in order to differentiate between these two theories. They are double salts of tin halogenides, all of the type SnA_n , but containing different numbers of halogen atoms, and alkali halogenides or similar compounds. According to the Blomstrand-Remsen theory, the number of molecules of alkali halogenide added is a function of the number of halogen atoms in the tin halogenide; by the Werner theory the number added is independent of the number of halogen atoms in the tin halogenide. The existence of compounds, such as $\text{SnPh}_3\text{Cl}_2 \cdot 2\text{C}_6\text{NH}_5 \cdot 2\text{HCl}$ and

is contrary to the Blomstrand-Remsen theory.

Pyridinium stannichloride, $2\text{Py} \cdot \text{H}_2\text{SnCl}_6$, obtained from pyridine and stannic chloride in concentrated hydrochloric acid, and *quinolinium stannichloride*, $2\text{Qn} \cdot \text{H}_2\text{SnCl}_6$ ($\text{Qn} = \text{C}_9\text{H}_7\text{N}$), m. p. 266° , similarly prepared, form colourless crystals; the *stannibromides*, $2\text{Py} \cdot \text{H}_2\text{SnBr}_6$ and $2\text{Qn} \cdot \text{H}_2\text{SnBr}_6$, m. p. $258-261^\circ$, are yellow. *Pyridinium stannii-iodide*, $2\text{Py} \cdot \text{H}_2\text{SnI}_6$, prepared from pyridine hydriodide and stannic iodide in alcoholic hydrogen iodide, forms dark brown leaflets (compare Rosenheim and Aron, Abstr., 1904, ii, 411. The substance described by these authors as forming bluish-black needles is pyridinium periodide, HPyI_3). *Pyridinium stannimethylpentachloride*, $[\text{SnCl}_5\text{Me}]2\text{HPy}$, and the *quinolinium salt*, $[\text{SnCl}_5\text{Me}]2\text{HQn}$, m. p. 200° (decomp.), obtained from methylstannic acid and pyridine or quinoline in cold concentrated hydrochloric acid, form colourless crystals. *Pyridinium stannimethylpentabromide*, $[\text{SnBr}_5\text{Me}]2\text{HPy}$, m. p. $165-172^\circ$ (decomp.), and the *quinolinium salt*, $[\text{SnBr}_5\text{Me}]2\text{HQn}$, m. p. $80-145^\circ$ (decomp.), obtained from alcoholic tin methyl bromide and pyridine or quinoline in concentrated hydrobromic acid, crystallise in yellow needles. Stannimethylpentaiodides cannot be prepared. *Pyridinium stannidimethyltetraochloride*, $[\text{SnCl}_4\text{Me}_2]2\text{HPy}$, m. p. $143-144^\circ$, and the *quinolinium salt*, $[\text{SnCl}_4\text{Me}_2]2\text{HQn}$, m. p. 167° , obtained from tin dimethyl chloride (m. p. 108° , not 90°) and pyridine or quinoline hydrochloride in methyl-alcoholic hydrogen chloride, form colourless needles. The corresponding *stannidimethyltetrabromide*, $[\text{SnBr}_4\text{Me}_2]2\text{HPy}$, m. p. $108-112^\circ$, and $[\text{SnBr}_4\text{Me}_2]2\text{HQn}$, m. p. 134° , prepared in a similar manner, are colourless, but gradually become yellow by keeping. The following six compounds are also prepared in a similar manner: $[\text{SnCl}_4\text{Et}_2]2\text{HPy}$, m. p. $118-122^\circ$, colourless prisms;

m. p. $134-135^\circ$, stable, colourless needles; $[\text{SnBr}_4\text{Et}_2]2\text{HPy}$, m. p. $90-99^\circ$, colourless needles; $[\text{SnBr}_4\text{Et}_2]2\text{HQn}$, m. p. $120-124^\circ$, colourless needles; $[\text{SnCl}_4\text{Pr}^a]2\text{HPy}$, m. p. 114° , colourless plates; $[\text{SnBr}_4\text{Pr}^a]2\text{HPy}$, m. p. $100-114^\circ$, colourless leaflets. *Pyridinium stannidiphenyltetraochloride*, $[\text{SnCl}_4\text{Ph}_2]2\text{HPy}$, m. p. 186° , obtained from stannic diphenyl oxide and pyridine hydrochloride in saturated methyl- or ethyl-alcoholic hydrogen chloride, and the *quinolinium salt*, $[\text{SnCl}_4\text{Ph}_2]2\text{HQn}$, m. p. $133-140^\circ$, similarly prepared, form colourless

crystals. The corresponding *bromo-compounds*, $[\text{SnBr}_3\text{Ph}_3]_2\text{HPPy}$, m. p. 195° , and $[\text{SnBr}_3\text{Ph}_3]_2\text{HQn}$, m. p. $119-129^\circ$ or $130-131^\circ$ (different samples), are likewise colourless. *Pyridinium stannitriphenyltrichloride*, $[\text{SnClPh}_3]_2\text{HPPy}$, m. p. $169-170^\circ$, obtained from stannic triphenyl chloride (m. p. $112-113^\circ$, not 106°) and pyridine hydrochloride in methyl-alcoholic hydrogen chloride, and *pyridinium stannitriphenyltribromide*, $[\text{SnBr}_3\text{Ph}_3]_2\text{HPPy}$, m. p. $146-153^\circ$ or, after resolidification, 194° , similarly prepared, form colourless crystals, and are the only substances which can be obtained from tin halogenides of the type SnR_3Cl . C. S.

Betaines of Pyridinium-maleic and Pyridiniumacrylic Acids and their Salts. PAUL PREIFFER and A. LANGENBURG [in part with Miss BIRENCKWIG] (*Ber.*, 1910, 43, 2926-2939. Compare O. Lutz, following abstract).—When dibromosuccinic acid is treated with pyridine, a mixture of pyridino salts is obtained, which, on warming, evolves carbon dioxide, and leaves a residue from which two substances can be isolated. Of these, one contains ionic bromine, has acid properties, and is identical with the compound obtained from pyridine and α -bromoacrylic acid. To it is therefore ascribed the structure of α -pyridiniumacrylic acid bromide, $\text{C}_5\text{H}_5\text{N}^+\cdot\text{Br}\cdot\text{C}(\text{CH}_3)\cdot\text{CO}_2\text{H}$. The other substance yields an additive product with hydrogen bromide, which, on heating, loses carbon dioxide and is converted into α -pyridiniumacrylic acid bromide, so that it probably has the structure of a betaine of pyridinium-maleic acid, $\text{C}_5\text{H}_5\text{N}^+\cdot\text{C}(\text{CH}_3)\cdot\text{CH}\cdot\text{CO}_2\text{H}$ or $\text{O}\cdot\text{CO}$

$$\text{C}_5\text{H}_5\text{N}^+ \text{---} \begin{array}{c} \text{C} \cdot \text{CO}_2\text{H} \\ | \\ \text{O} \cdot \text{CO} \cdot \text{CH} \end{array}$$

, the maleic structure being more probable than

the fumaric, because quinoline and dibromosuccinic acid yield quinoline bromomaleate. The salts described give with alkalis yellow solutions, becoming blood-red (compare the colour reactions of dinitrophenyl pyridinium salts: Zincke, *Abstr.*, 1907, i, 625).

Dibromosuccinic acid and excess of pyridine on standing for two days at the ordinary temperature yield the *tripyrindine* salt,

as a white powder, which when kept over sulphuric acid loses pyridine, forming the *monopyridine* salt, $\text{C}_4\text{H}_4\text{O}_4\text{Br}_2\cdot\text{C}_5\text{H}_5\text{N}$, which after crystallisation forms colourless needles, m. p. about 143° (with evolution of gas).

Pyridine bromomaleate, $\text{C}_4\text{H}_3\text{O}_4\text{Br}\cdot\text{C}_5\text{H}_5\text{N}$ (from bromomaleic acid in ethereal solution), is a white, crystalline precipitate, m. p. $94-100^\circ$. *Pyridine bromofumarate*, $\text{C}_4\text{H}_3\text{O}_4\text{Br}\cdot\text{C}_5\text{H}_5\text{N}$, may be prepared in the same way.

Quinoline bromomaleate, $\text{C}_4\text{H}_3\text{O}_4\text{Br}\cdot\text{C}_9\text{H}_7\text{N}$, is obtained on heating dibromosuccinic acid for some hours with quinoline; it forms colourless needles, m. p. $114-115^\circ$ (with evolution of gas), and yields bromomaleic acid on treatment with ammonia.

The betaine of *pyridinium-maleic acid* is obtained by heating dibromosuccinic acid with pure pyridine for one hour at $60-70^\circ$. The

α-pyridiniumacrylic acid bromide, which is also produced, is removed by the addition of a little water, in which it is very soluble. The betaine becomes brown at 195°. Sodium carbonate dissolves it with evolution of carbon dioxide. When the substance is dissolved in concentrated hydrochloric acid and evaporated on the water-bath, *pyridiniummaleic acid chloride*, $C_5H_5NCl \cdot C(CO_2H) : CH \cdot CO_2H$, is obtained; it crystallises in small white colourless tablets, which decompose at 150° with evolution of gas, having become brown a few degrees previously. The *bromide* may be obtained similarly, or, better, (1) by adding the betaine to concentrated hydrobromic acid until the salt separates out; (2) by evaporating over soda-lime a solution of the betaine in concentrated hydrobromic acid. It forms colourless, prismatic crystals, which decompose at 170°. On heating it to 110°, *α*-pyridiniumacrylic acid bromide is obtained.

α-Pyridiniumacrylic acid bromide is also obtained by warming pyridine with dibromosuccinic acid (*v.s.*), bromomaleic acid, bromofumaric acid, *αβ*-dibromopropionic acid, or *α*-bromoacrylic acid. It forms colourless needles, m. p. 216° (decomp.). With moist silver oxide it gives the betaine in solution. It gives precipitates with potassium dichromate, gold and platinum solutions. *α*-Pyridiniumacrylic acid chloride, $C_5H_5NCl \cdot H_2O$, is prepared from the bromide by the action of moist silver oxide followed by hydrochloric acid; it forms colourless needles, m. p. 195° (decomp.). The *platinichloride*,

$(C_5H_5O_2N)_2PtCl_4 \cdot 4H_2O$, darkens on heating, and decomposes at 196°. The *platinichloride*, $(C_5H_5O_2N)_2PtCl_4 \cdot 4H_2O$, decomposes at 200°. The *picrate*,

$C_5H_5O_2N \cdot O \cdot C_6H_3(NO_2)_3$, has m. p. about 158° (decomp.).

R. V. S.

Characteristic Reaction of Maleic Acid. OSCAR LUTZ (*Ber.*, 1910, 43, 2636—2641).—Anhydropyridiniumsuccinic acid (pyridine-aminosuccinic acid, Abstr., 1901, i, 8) is also formed when *dl*-bromosuccinic acid is treated with pyridine under the conditions described by Dubrenil (Abstr., 1904, i, 189), and is the substance described by Dubreuil as pyridine hydrogen fumarate. The anhydro-compound can also be obtained from maleic acid, for example, (a) when pyridine hydrogen malcato is heated at its melting point (165°) for 15—20 minutes; (b) by keeping an aqueous-alcoholic or methyl alcoholic solution of pyridine and maleic acid at the ordinary temperature for several weeks.

Anhydropyridiniumsuccinic acid, $C_5H_5N \begin{matrix} \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}_2 \\ \text{O} \cdot \text{CO} \end{matrix}$ or $C_5H_5N \begin{matrix} \text{O} \cdot \text{CO} \\ \text{CH} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H} \end{matrix}$, has m. p. 192°, and its solubility in water at 18° is 1.65.

This reaction of maleic acid with pyridine is used as an argument in favour of the structural formula $\text{CO}_2\text{H} \cdot \text{CH} \begin{matrix} \text{O} \\ \text{CH}_2 \end{matrix} \text{CO}$, for maleic acid,

J. J. S.

Conversion of Hydrogenised Carbazoles into Derivatives of 2-Aminodiphenyl. JULIUS VON BRAUN (*Ber.*, 1910, 43, 2879—2888).—In the form of their benzoyl derivatives, the hexahydrocarbazole compounds obtained by the reduction of the corresponding tetrahydrocarbazoles, prepared from cyclohexanones by Fischer's indole synthesis, are readily ruptured by phosphorus pentachloride. Thus hexahydrocarbazole is converted into its benzoyl derivative, b. p. about 270°/10 mm., which yields 20—25% of 2-benzoylamino diphenyl when heated with phosphorus pentachloride, first on the water-bath and finally at 120°. In a similar manner, 1-benzoyl-4-methylhexahydrocarbazole yields 2-benzoylamino-4'-methyldiphenyl, $C_6H_4Me \cdot C_6H_4 \cdot NH \cdot Bz$, m. p. 122°.

CS

Tricyclic Quinolines. WALTHER BORSCHKE [with R. SCHMIDT, H. TIEDTKE, and W. ROTTSIEPER] (*Annalen*, 1910, 377, 70-123).—Quinoline derivatives containing a third ring condensed on the pyridine nucleus in positions 2:3 or 3:4 have been prepared by the three following methods: 1. Condensation of primary arylamines with semicyclic ketones obtained from alicyclic ketones and esters, 2. Condensation of alicyclic ketones containing the grouping $-\text{CO}\cdot\text{CH}_2-$ with *o*-acylanilides. 3. Condensation of isatic acid with alicyclic ketones to acids of the desired bases, and subsequent elimination of carbon dioxide.

The products, for example, $C_6H_4 \begin{matrix} CH:C\cdot CH_2 \\ N=C\cdot CH_3 \end{matrix} > CH_2$ and

are regarded as 2:3-disubstituted quinolines, and are termed 2:3-trimethylenequinoline and 2:3-pentamethylenequinoline. The corresponding tetramethylene compounds are regarded as derived from tetrahydroacridine.

The general nomenclature of cyclic systems is discussed. The Greek capitals *gamma* Γ , *tau* T , and *pi* Π are suggested for a bridge, an acetylene linking, and a diagonal linking respectively; piene is thus 1-methyl- $\Gamma^{2,4}$ -dimethylmethylenecyclohexene, camphane is 1-methyl- $\Gamma^{1,4}$ -dimethylmethylenecyclohexane, tropan is $\Gamma^{1(4)}$ -methylimino-cycloheptane, thujone is 1-methyl-4-isopropyl- $\Pi^{4(6)}$ -cyclohexan-2-one, and Moyocho and Zienkowski's tricyclene (Abstr., 1905, i, 711) is 1:1-dimethyl- $\Gamma^{2,5}$ -methylenecyclo- $\Pi^{3,7}$ -cycloheptane.

The following considerations are of importance in the numbering of the atoms of ring systems. 1. The system should indicate as far as possible the analogies in the structure of closely related compounds, for example, anthracene, xanthon, and acridine, phenanthrene and phenanthridine, etc. 2. The system should admit a numbering of the analogous reduced cyclic compounds without any alterations in the relative numbering of the substituents. The conditions would be fulfilled by the following system. The cyclic system is so written that as many directly condensed rings as possible lie on a straight line. Each atom of a ring system is numbered, including, for example (unlike the system adopted in Richter's *Lexikon der Kohlenstoff-Verbindungen*), the carbon atoms common to two rings in the naphthalene, anthracene, and similar systems.

The numbering begins at the top of the ring on the extreme right (that is, the atom in the ortho-position to the second ring), and each atom of the first ring is numbered before proceeding to the second ring; for example:

This re-numbering is not followed in the abstract.]

Hydroxymethylenecyclohexanone (Wallach, Abstr., 1904, i, 105) is best prepared by the action of sodium wire on a mixture of *cyclohexanone* and *isoamyl formate*. It has b. p. $87^{\circ}/14$ mm., and tends to resinify when kept. With aniline, it yields *α-ketohexahydrobenzylidene aniline*, $\text{CH}_2\langle\begin{smallmatrix} \text{CH}_2\cdot\text{CH}_2 \\ \text{CH}_2\cdot\text{CO} \end{smallmatrix}\rangle\text{CH}\cdot\text{CH}\cdot\text{NPh}$, which crystallises from alcohol

in yellow needles, m. p. 154° . Heating with concentrated sulphuric acid transforms this compound into *α-ketohexahydrobenzylideneaniline-p-sulphonic acid*, $\text{C}_{13}\text{H}_{15}\text{O}_3\text{NS}$, which can also be obtained by condensing hydroxymethylenecyclohexanone with aniline-*p*-sulphonic acid in the presence of *N*-potassium hydroxide. It forms yellow needles, m. p. $261\text{--}263^{\circ}$, yields an *ammonium salt* in the form of yellow plates, and a *potassium salt* in the form of rhombic crystals, m. p. $269\text{--}270^{\circ}$ (decomp.).

α-Ketohexahydrobenzylidene-m-aminophenol, $\text{C}_{13}\text{H}_{15}\text{O}_3\text{N}$, prepared by condensing the components in glacial acetic acid solution, crystallises in yellow needles, m. p. $172\text{--}173^{\circ}$. Neither of the above condensation products yields a quinoline derivative.

Acetylcyclohexan-2-one, $\text{CH}_2\langle\begin{smallmatrix} \text{CH}_2\text{--CO} \\ \text{CH}_2\text{--CH}_2 \end{smallmatrix}\rangle\text{CHAc}$, prepared by the condensation of *cyclohexanone* and ethyl acetate with sodium, is best isolated as its *copper derivative* in the form of a greenish-grey, crystalline powder, m. p. $160\text{--}161^{\circ}$. The free ketone is a colourless oil with b. p. $97\text{--}98^{\circ}/11$ mm., and can be kept for some time. It condenses with *m*-aminophenol in glacial acetic acid solution, yielding the *m-hydroxyanil*, $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{N}\cdot\text{C}_6\text{H}_9\text{Ac}$, as yellow needles, m. p. $186\text{--}187^{\circ}$, which react with concentrated sulphuric acid at 100° , yielding the quinoline derivative, *5-methyl-8-hydroxy-1:2:3:4-tetrahydroacridine* (*5-methyl-1-hydroxy-2:3-hexamethylenequinoline*: annexed formula). The *sulphate* crystallises from dilute alcohol in yellowish-white needles, m. p. 225° , and the free base crystallises in glistening plates, which darken at 240° , but are not completely molten at 360° ; its solutions have a yellowish-green fluorescence.

Aniline and *d*-4-acetyl-1-methylcyclohexan-3-one react at 150° , yielding a mixture of isomeric anils, $\text{COMe}\cdot\text{C}_6\text{H}_8\text{Me}\cdot\text{NPh}$ and

or the tautomeric enolic forms. A mixture of the two has b. p.

211°/14 mm., and cannot be separated; the mixture, when heated for three hours with concentrated sulphuric acid on the water-bath, yields a mixture of the two quinoline bases, $C_{15}H_{17}N$, namely:

A mixture of the two has b. p. 200°/14 mm., and the separation is based on the fact that the former yields a sparingly soluble hydrochloride and the latter a sparingly soluble dichromate. The acridine base crystallises from light petroleum in colourless needles, m. p. 72–74°, and $[\alpha]_D + 57.07^\circ$. Its solutions in acids have a greenish-yellow fluorescence. The *picrate* forms a yellow, crystalline powder, m. p. 193°; the *methiodide*, $C_{16}H_{20}NI$, crystallises from alcohol in yellow needles, m. p. 232–233°; the *platinichloride*,

$2C_{15}H_{17}N_2H_2PtCl_6$, forms orange-coloured needles, m. p. 213–223°, and the *aurichloride*, $2C_{15}H_{18}NCl_2AuCl_3$, yellow needles, m. p. 166°. The same base can also be prepared by condensing *o*-aminoacetophenone with *d*-3-methylcyclohexanone, and when distilled with zinc dust in an atmosphere of hydrogen yields 2:5-dimethylacridine, $C_{15}H_{15}N$, colourless needles, m. p. 121–122°, the *picrate* of which is sparingly soluble in hot alcohol and has m. p. 225°. A by-product is 2:5-dimethyl-5:10-di-hydroacridine, $C_{15}H_{17}N$, which crystallises from alcohol in colourless plates, m. p. 165–166°.

The dimethyltetrahydrophenanthridene crystallises from light petroleum, has m. p. 78° and $[\alpha]_D + 133.7^\circ$, and its solutions in acids do not fluoresce. The *picrate* has m. p. 208° (decomp.); the *aurichloride*, $C_{15}H_{17}N_2HAuCl_4$, crystallises in yellow needles, m. p.

128°. 9:10-Dimethylphenanthridene, $C_{15}H_{15}N$, is a colourless oil, and yields a *picrate*, m. p. 214°.

in yellow, crystalline aggregates, m. p. 153–154°, and with sulphuric acid yields 2:5-dimethyl-8-hydroxy-1:2:3:4-tetrahydroacridine

(formula I). This forms greenish-yellow crystals, m. p. 272–273°, and yields a *sulphate* in the form of colourless needles, m. p. 207–208°. When distilled with zinc dust in an atmosphere of hydrogen, the base yields 2:5-dimethylacridine.

d-α-Acetylcamphor-*m*-hydroxyanil, $C_{10}H_{15}Ac \cdot N \cdot C_6H_4 \cdot OH$,

crystallises from alcohol in colourless, flat needles, m. p. 151–152°, and with concentrated sulphuric acid yields the quinoline base, $C_{15}H_{15}ON$ (formula 11). This crystallises in yellow needles, which are unaltered at 360°, and yields a *picrate*.

1 : 2 : 3 : 4-Tetrahydroacridine-5-carboxylic acid,

prepared by condensing *cyclohexanone* with *isatin* in the presence of 33% potassium hydroxide and alcohol, crystallises in colourless, glistening plates, m. p. 284—286° (decomp.). The *picrate* forms yellow needles, m. p. 199.5° (decomp.); the *aureichloride*,

has m. p. 237° (decomp.); the *platinichloride*,

forms glistening, brown crystals, m. p. 222—223°; and the *methyl ester*, $\text{C}_{13}\text{H}_{12}\text{N} \cdot \text{CO}_2\text{Me}$, prepared from the silver salt, has b. p. 200°/24 mm. and m. p. 70°; it yields a *picrate*, m. p. 176—178°, and a *platinichloride*, as red needles, m. p. 204—208°; the *ethyl ester*,

forms broad needles, m. p. 55°, and yields a *picrate*, m. p. 166—167°, a *platinichloride*, $2\text{C}_{13}\text{H}_{11}\text{O}_2\text{N}, \text{H}_2\text{PtCl}_6$, m. p. 193—194°, and an *ethiodide*, $\text{C}_{13}\text{H}_{22}\text{O}_2\text{NI}$, m. p. 168°. 1 : 2 : 3 : 4-Tetrahydroacridine, prepared by heating the carboxylic acid at its m. p., yields a *sulphate*, with m. p. 148°, and a *mercurichloride*, in the form of colourless needles, m. p. 213—214°. The base condenses with benzaldehyde and zinc chloride at 160—170°, yielding 1-benzylidene-1 : 2 : 3 : 4-tetrahydroacridine,

which crystallises from dilute alcohol in glistening plates, m. p. 103—104°. Its *picrate* has m. p. 176—178°. Tetrahydroacridine and phthalic anhydride yield a *phthalone*. When nitrated with 10% nitric acid, the tetrahydro-base yields a mixture of two *nitro-derivatives*, $\text{C}_{13}\text{H}_{12}\text{N} \cdot \text{NO}_2$, namely, dark yellow prisms, melting at 126—130°, and yellow needles, m. p. 138—139°, which have to be separated mechanically. With fuming sulphuric acid at 100°, the base yields *tetrahydroacridine-6-sulphonic acid*, $\text{C}_{13}\text{H}_{13}\text{O}_3\text{NS}$, which crystallises from water in colourless prisms, but at 130—140° the chief product is an isomeric *sulphonic acid*, m. p. 248—250°, together with a small amount of the above sulphonic acid, which is not molten at 300°, and of a *disulphonic acid*.

The base reacts with bromine, yielding the *hydrobromide perbromide* $\text{C}_{13}\text{H}_{13}\text{N}, \text{HBr}$, as yellowish-red needles, m. p. 123°.

7-Bromo-1 : 2 : 3 : 4-tetrahydroacridine-5-carboxylic acid,

prepared from *cyclohexanone*, 5-bromoisatin, and alkali, crystallises in minute needles, m. p. 274—276°, after drying at 120°. When heated at its m. p., the acid yields 7-bromotetrahydroacridine, $\text{C}_{13}\text{H}_{12}\text{NBr}$, which crystallises from alcohol in flat needles, m. p. 93—94°. The *picrate* crystallises in greenish-yellow plates, m. p. 194—195°, and the *aureichloride* in microscopic needles, m. p. 208°. 7 : 9-Dibromo-1 : 2 : 3 : 4-tetrahydroacridine-5-carboxylic acid, $\text{C}_{14}\text{H}_{11}\text{O}_3\text{NBr}_2$, prepared from 3 : 5-dibromoisatin, crystallises in broad needles, m. p. 242°. 7 : 9-Dibromotetrahydroacridine, $\text{C}_{13}\text{H}_{11}\text{NBr}_2$, crystallises in yellow needles, m. p. 105—107°.

d-2-Methyl-1:2:3:4-tetrahydroacridine-5-carboxylic acid,

obtained from isatin and d-1-methylcyclohexan-3-one, crystallises from glacial acetic acid in yellow needles, m. p. 291—293° (decomp.). d-2-Methyltetrahydroacridine, $\text{C}_{14}\text{H}_{15}\text{N}$, crystallises from light petroleum in colourless, slender plates, m. p. 81—82°, and yields a *picrate*, m. p. 176—177°. The corresponding *dl*-base has m. p. 72—73°, and both the *d*- and the *dl*-base when heated with lead oxide yield 3-methylacridine, the *dichromate* of which forms red needles, m. p. 125—126°.

Isatin and 1-methylcyclohexan-4-one yield 3-methyl-1:2:3:4-tetrahydroacridine-5-carboxylic acid,

in the form of yellow needles, m. p. 280—281°. 3-Methyltetrahydroacridine, $\text{C}_{14}\text{H}_{15}\text{N}$, crystallises from light petroleum in quadrilateral plates, m. p. 84—85°, and yields a *picrate*, m. p. 194—195°. When heated with lead oxide, the base yields 3-methylacridine (Ullmann, Abstr., 1888, 288).

Pulegone and isatin in the presence of concentrated potassium hydroxide yield α -methyleinchonic acid, together with neutral products, probably owing to the conversion of the pulegone into acetone and 1-methylcyclohexan-3-one.

2:3-Trimethylenecinchonic acid, $\text{C}_6\text{H}_4 \begin{array}{c} \text{C}(\text{CO}_2\text{H})\cdot\text{C}\cdot\text{CH}_2\cdot\text{CH}_2 \\ \text{N}\cdot\text{C}\cdot\text{CH}_2\cdot\text{CH}_2 \end{array} \text{CH}_3$

obtained from isatin, cyclopentanone, and alkali, crystallises from alcohol or glacial acetic acid in small needles, m. p. 277—278° (decomp.). 2:3-Trimethylenequinoline, $\text{C}_{12}\text{H}_{11}\text{N}$, formed when the acid is heated at its m. p. or by condensing cyclopentanone with *o*-aminobenzaldehyde, crystallises from light petroleum in colourless needles, m. p. 59—60°; the *dichromate* forms sparingly soluble, orange, yellow prisms; the *picrate*, pale yellow needles, m. p. 203—204°; the *aurichloride*, $\text{C}_{12}\text{H}_{11}\text{N}, \text{HAuCl}_4$, needles, m. p. 160—162°; the *platinichloride*, reddish-yellow needles, m. p. 235°; and the *methiodide*, $\text{C}_{12}\text{H}_{11}\text{Nl}$, pale yellow crystals, m. p. 207°.

2:3-Pentamethylenecinchonic acid,

crystallises from glacial acetic acid in glistening needles, m. p. 291—292°, and 2:3-pentamethylenequinoline, $\text{C}_{14}\text{H}_{15}\text{N}$, from light petroleum in colourless needles, m. p. 93·5°; its *hydrochloride* forms broad needles, m. p. 107—108°; its *picrate*, yellow needles, m. p. 197°; its *methiodide* has m. p. 195—196°; its *aurichloride*,

forms yellow needles, m. p. 179°, and its *platinichloride* crystallises with $2\text{H}_2\text{O}$ in orange-red needles, m. p. 214°.

J. J. S.

Oxazole Series. Syntheses of 2-Ketotetrahydro-oxazoles.
TREAT B. JOHNSON and RALPH W. LANGLEY (*Amer. Chem. J.*, 1910, 44, 352—361).—Nemirowsky (Abstr., 1885, 741) has shown that

carbonyl chloride reacts with β -chloroethyl alcohol at 200° to form β -chloroethyl chloroformate. When this ester was treated with aniline, chloroethyl phenylcarbamate, $\text{CH}_2\text{Cl}\cdot\text{CH}_2\cdot\text{O}\cdot\text{CO}\cdot\text{NHPh}$, was produced, and was converted by alkali hydroxide into 2-keto-3-phenyl-tetrahydro-oxazole, $\text{O} \begin{array}{c} \text{CO}-\text{NPh} \\ \diagup \quad \diagdown \\ \text{CH}_2 \cdot \text{CH}_2 \end{array}$. Otto (Abstr., 1891, 1373) studied

the action of carbonyl chloride on the dichlorohydrins, and obtained acid chlorides, from which he prepared a series of urethanes. He found that the urethanes from $\alpha\alpha$ -dichlorohydrin yielded ketotetrahydro-oxazoles when they were treated with alkali hydroxide, whilst those from $\alpha\beta$ -dichlorohydrin did not behave in this way. In view of these results, a study has now been made of various halogenalkyl phenylcarbamates and their behaviour towards alkali hydroxide.

$\beta\beta$ -Dichloroisopropyl phenylcarbamate, $\text{CH}(\text{CH}_2\text{Cl})_2\cdot\text{O}\cdot\text{CO}\cdot\text{NHPh}$, m. p. 73° , obtained by the action of phenylcarbimide on $\alpha\alpha$ -dichlorohydrin at 100° , crystallises in groups of slender needles, and when heated with potassium hydroxide is converted almost quantitatively into 2-keto-3-phenyl-5-chloromethyltetrahydro-oxazole,

(Otto, *loc. cit.*).

$\beta\beta'$ -Chlorobromoisopropyl phenylcarbamate, m. p. 73° , obtained by the interaction of phenylcarbimide and $\beta\beta'$ -chlorobromoisopropyl alcohol, crystallises in needles, and is converted by potassium hydroxide into 2-keto-3-phenyl-5-chloromethyltetrahydro-oxazole.

β -Chloro- γ -bromopropyl phenylcarbamate, m. p. 73° , was prepared from phenylcarbimide and β -chloro- γ -bromopropyl alcohol. γ -Chloro- β -bromopropyl phenylcarbamate, m. p. $75-76^\circ$, is converted by potassium hydroxide into 2-keto-3-phenyl-4-chloromethyltetrahydro-oxazole,

m. p. $73-78^\circ$, which forms groups of needles. A small yield of this oxazole was also obtained by the action of potassium hydroxide on $\beta\beta'$ -dichloropropyl phenylcarbamate. $\beta\beta'$ -Dibromoisopropyl, $\beta\gamma$ -dichloropropyl, and $\beta\gamma$ -dibromopropyl phenylcarbamates have m. p. 73° , $72-73^\circ$, and $77-79^\circ$ respectively. E. C.

Oxazole Series: the Addition of Cyanic Acid to Epichlorohydrin. TREAT B. JOHNSON and HERBERT H. GUEST (*Amer. Chem. J.*, 1910, 44, 5, 453-466).—Thomsen (Abstr., 1879, i, 217) has described the formation of a ketotetrahydro-oxazole, $\text{C}_4\text{H}_5\text{O}_2\text{NCl}$, from the action of potassium cyanate on epichlorohydrin. The authors have synthesised this substance by the action of strong alkali on $\beta\beta'$ -dichloroisopropyl acetylcarbamate, and thus determined the manner of addition of cyanic acid to epichlorohydrin. It is shown that theoretically three isomeric cyclic compounds might be formed by this addition: 2-keto-5-chloromethyltetrahydro-oxazole, 2-keto-4-chloromethyltetrahydro-oxazole, and γ -chloropropylene imino-carbonate, and that the substance formed must be assigned the structure of the first of these.

$\beta\beta'$ -Dichloroisopropyl acetylcarbamate, $\text{NHAc}\cdot\text{CO}_2\cdot\text{CH}(\text{CH}_2\text{Cl})_2$, crystallises in needles, m. p. 100° .

$\beta\beta'$ -Dichloroisopropyl benzoylcarbamate crystallises in rectangular prisms, m. p. 119° . 2-Keto-3-phenylcarbamyl-5-chloromethyltetrahydro-

oxazole, $\text{CH}_2\text{Cl}\cdot\text{CH}\begin{matrix} \text{O}=\text{C} \\ \text{CH}_2\cdot\text{N}\cdot\text{CO}\cdot\text{NHPh} \end{matrix}$, forms rhombic tablets, m. p. 154 — 155° ; the corresponding 3-benzoylcarbamyl derivative melts at 131 — 132° .

β - γ -Dichloropropyl acetylcarbamate forms prisms, m. p. 64 — 65° .

Allyl acetylcarbamate crystallises in flat prisms, m. p. 64° .

γ -Chloro- β -bromopropyl acetylcarbamate crystallises in prisms, m. p. 60° . γ -Chloro- β -bromopropyl carbamate forms plates, m. p. 93° .

$\beta\beta'$ -Dibromoisopropyl benzoylcarbamate crystallises in plates, m. p. 119° ; the β -chloro- β -bromo-derivative melts at 122° .

β - γ -Dichloropropyl benzoylcarbamate and the corresponding di-bromo-derivative melt at 83° .

γ -Chloro- β -bromopropyl benzoylcarbamate forms tabular crystals, m. p. 113° .

β -Chloro- γ -bromopropyl benzoylcarbamate crystallises in prisms, m. p. 114° . N. C.

Diphenylene-sultam. FRITZ ULLMANN and CHRISTIAN GROSS (Ber., 1910, 43, 2694—2704).—A sultam could not be obtained from toluene-*p*-sulpho-3-nitro-*p*-toluidide, but one was prepared from *o*-nitro-benzenesulphonanilide, the reduction product of which,

was diazotised, and on the addition of sodium acetate formed

1-phenyl-benzsulphontriazine, $\text{C}_6\text{H}_4\begin{matrix} \text{SO}_2\cdot\text{NPh} \\ \text{N}=\text{N} \end{matrix}$; this was converted

by sodium hydroxide and copper into diphenylene-sultam,

Phenylenenaphthylene-sultam was prepared in a similar manner. Both sultams are colourless, crystalline compounds of strongly acid character. The ring is not opened on heating with hydrochloric acid even under pressure.

Nitro-*p*-toluenesulphonyl-3:5-dinitro-*p*-toluidide, prepared by nitration of *p*-toluenesulphonyl-*p*-toluidide, crystallises in colourless prisms, m. p. 184° . Sulphuric acid converts it into 3:5-dinitro-*p*-toluidine. With methyl sulphate, *p*-toluenesulphonylmethyl-3:5-dinitro-*p*-toluidide is formed in faintly yellow crystals, m. p. 199° .

p-Toluenesulphonyl-3-nitro-*p*-toluidide, produced on nitrating with 18% nitric acid at 60 — 70° , forms yellow prisms, m. p. 101° . It yields 3-nitro-*p*-toluidine when hydrolysed. When reduced with stannous chloride, *p*-toluenesulphonyltolylene-3:4-dianiline is obtained; it crystallises in needles, m. p. 140° ; the hydrochloride forms colourless, silky needles, decomp. 170° . *p*-Toluenesulphonylazirine-toluene forms colourless needles, m. p. 159° . *p*-Toluenesulphonylmethyl-3-nitro-*p*-toluidide has m. p. 124° . *p*-Toluene sulphonylmethyl-3-amino-*p*-toluidide forms colourless, matted needles, m. p. 133° .

Di-p-toluenesulphonyl-3-nitro-p-toluidide forms colourless needles, m. p. 228°; reduction converts it into *di-p-toluenesulphonyl-tolylene diamine*, crystallising in colourless needles, m. p. 192°.

o-Nitrobenzenesulphonanilide has m. p. 115°; *o-aminobenzenesulphonanilide* forms matted needles, m. p. 122°; the *hydrochloride* separates in colourless needles.

Diphenylene-sultam crystallises in well-formed, colourless, lustrous needles, m. p. 196°; it dissolves in ammonia and alkalis with a faint yellow coloration and bluish fluorescence. The mother liquors of the preparation contain *hydroxybenzenesulphonanilide*, colourless needles, m. p. 123°.

1-Phenylbenzsulphontriazine (annexed formula) is amorphous, m. p. 111° (decomp.). The triazine ring is immediately opened by dilute mineral acids, and the clear solutions couple with β -naphthol, forming red azo-dyes.

Diphenylene-N-methylsultam is obtained from *nitrobenzene sulphonmethylanilide*, m. p. 73°, which is reduced by stannous chloride to *aminobenzene-sulphonmethylanilide*, forming colourless crystals, m. p. 63°. The last substance when diazotised, and the diazonium solution evaporated, gives the *sultam* in colourless needles, m. p. 112°.

o-Nitrobenzenesulphonyl- β -naphthalide forms colourless needles, m. p. 158°; on reduction, *o-aminobenzenesulphonyl- β -naphthalide* is formed, crystallising in needles, m. p. 113°.

1- β -Naphthyl-benzsulphontriazine, $C_6H_4 \begin{smallmatrix} N=N \\ \diagup \quad \diagdown \\ SO_2 \cdot N \cdot C_{10}H_7 \end{smallmatrix}$ separates in colourless needles, m. p. 107–108°.

Phenylenenaphthalene-sultam, $C_6H_4 \begin{smallmatrix} SO_2 \\ \diagup \quad \diagdown \\ C_{10}H_6 \end{smallmatrix} NH$, crystallises in colourless needles, m. p. 254°; the solutions fluoresce faintly blue.

E. F. A.

Isomerism of Complex Compounds. I. Asymmetric Complex Compounds of Platinum. IWAN OSTROMISLENSKY and AUGUST BERGMANN (*Ber.*, 1910, 43, 2768–2774; *J. Russ. Phys. Chem. Soc.*, 1910, 42, 611–624).—The object of the authors was

to prepare complex compounds of platinum of the type $\begin{smallmatrix} a \\ b \end{smallmatrix} \begin{smallmatrix} m \\ n \end{smallmatrix} Pt \begin{smallmatrix} m \\ n \end{smallmatrix}$ or

$\left[\begin{smallmatrix} a \\ b \end{smallmatrix} \begin{smallmatrix} m \\ n \end{smallmatrix} Pt \begin{smallmatrix} m \\ n \end{smallmatrix} \right]_{m_2}$ in order to see if optical isomerides are capable of

existence. If this were so it would follow that Werner's explanation of the existence of two isomerides of the formula $Cl_2Pt(NH_3)_2$ is not a correct one. The stable, asymmetric compound, *cis-plato-pyridine-*

amine-chlorosulphite, $\begin{smallmatrix} Cl \\ HO_2S \end{smallmatrix} \begin{smallmatrix} NH_3 \\ \diagup \quad \diagdown \\ Pt \quad \diagdown \quad \diagup \\ NC_5H_5 \end{smallmatrix}$, has been prepared, but

so far no evidence of isomerism has been obtained.

To prepare the above compound, sulphur dioxide is passed into an aqueous suspension of plato-semipyridine-amine-chloride (*Abstr.*, 1886, 857) heated on the water-bath. The amine-chloride dissolves, leaving undissolved a small quantity of a yellow substance (*d*). The filtrate, on concentration, gives clear, colourless, monoclinic crystals

[$\alpha:b:c=0.966:1:0.712$; $\beta=91^{\circ}43'$] of the plato-pyridine-amine-chlorosulphite. With brucine it gives an easily soluble salt or double compound.

The mother liquors from the chlorosulphite sometimes deposit a yellow substance, which is identical with *A*. It is soluble in chloroform, and can thus be separated from the chlorosulphite, which is practically insoluble. It contains the same percentage of platinum and nitrogen as the chlorosulphite, but it is not isomeric or identical with it, as it does not contain sulphur. A formula is not given for it.

Plato-semitylenediamine chloride, $[C_7Pt(NH_2)_2 \cdot C_6H_5 \cdot CH_3]$, was obtained by warming potassium platinumchloride with 1:3:4-tylenediamine. It forms microscopic, yellow needles, with a green tinge, which are insoluble in ordinary solvents. Attempts to prepare an asymmetric complex from it by replacing one of the chlorine atoms by the SO_3H group were not successful. Treatment with sulphites, bisulphites, or sulphur dioxide gave precipitates which were analysed, but to which the authors assign no formula.

Plato-semiisobutylenediamine chloride, as also the asymmetric compound, $\left[\begin{array}{c} H_2C \cdot NH_2 \\ | \\ Me_2C \cdot NH_2 \end{array} \right]_2 Pt(NH_2)_2 \cdot C_6H_5 \cdot CH_3$, are not capable of existence.

T. S. P.

Nitrosohydrazines, isoAzotates [isoDiazo-compounds], and Azo-compounds of the Aliphatic Series. JOHANNES THIELE (*Annalen*, 1910, 376, 239—268; *Abstr.*, 1908, i, 927).—The main object of the paper is to show that aliphatic *isozotates* (isodiazo-compounds) behave like their aromatic analogues, except, of course, that they do not yield diazonium salts with acids.

The production of *isodiazo*-compounds from a primary hydrazine (or its nitroso-derivative, which has an asymmetric structure), ethyl nitrite, and sodium ethoxide is represented by the scheme: $NHR \cdot NH_2 \rightarrow N(NO)R \cdot NH_2 \rightarrow N_2O + NHR \cdot NO$ (a decomposition resembling that of *sec.-az*-hydrazines by nitrous acid) $\rightarrow RN:N \cdot ONa$. (The formation of Hantzsch and Lehmann's azotates, which are quite different from the *isozotates*, from nitroso-alkylurethanes and very concentrated potassium hydroxide is explained by the intermediate formation of the same primary nitroso-amine, $NHR \cdot NO$. Further research is necessary in order to explain the remarkable difference in the course of the two reactions.)

Methylhydrazine sulphate, which is conveniently prepared by heating a benzene solution of benzylideneazine with methyl sulphate for five hours and decomposing the additive product with water, is exactly neutralised by sodium hydroxide, and the solution is treated with three times the calculated amount of 5*N*-nitrite and is made distinctly acid with acetic acid; when the mixture becomes neutral, acetic acid is again added, and so on for about eight hours until the methylhydrazine has been converted into *nitrosomethylhydrazine*, $NO \cdot NMe \cdot NH_2$, m. p. 45° , which is then liberated by sodium carbonate and extracted with ether. Its aqueous solution develops an intense violet coloration with ferric chloride, yields a white precipitate with

mercuric salts, and gives a reddish-brown, crystalline precipitate, and ultimately a reddish-brown coloration, with copper sulphate after the addition of sodium acetate or hydroxide. It reacts with an aqueous suspension of benzaldehyde containing a trace of sulphuric acid to form *nitrosobenzylidenemethylhydrazine*, $\text{CHPh}\cdot\text{N}\cdot\text{NMe}\cdot\text{NO}$, m. p. $77-78^\circ$, with 10% sodium hydroxide and benzoyl chloride to form *benzoylnitrosomethylhydrazine*, $\text{NHBz}\cdot\text{NMe}\cdot\text{NO}$, m. p. $126-127^\circ$ (decomp., rapidly heated), and with $N/2$ -sodium hydroxide and benzenesulphonyl chloride to form *benzenesulphonylnitrosomethylhydrazine*, $\text{SO}_2\text{Ph}\cdot\text{NH}\cdot\text{NMe}\cdot\text{NO}$, m. p. 83° ; the last two compounds, like the corresponding derivatives of nitrosobenzylhydrazine,

m. p. $126-127^\circ$, and $\text{SO}_2\text{Ph}\cdot\text{NH}\cdot\text{N}(\text{NO})\cdot\text{CH}_2\text{Ph}$, m. p. $115-116^\circ$, do not develop a violet coloration with ferric chloride.

In methylhydrazine the nitrogen atom which is already alkylated is alone attacked by further methylation. Nitrosomethylhydrazine and nitrosobenzylhydrazine, however, readily react with methyl sulphate or benzyl chloride in the presence of aqueous sodium hydroxide, yielding *nitrosohydrazomethane*, $\text{NHMe}\cdot\text{NMe}\cdot\text{NO}$, b. p. $56^\circ/10\text{ mm.}$, *nitroso- α -dibenzylhydrazine*, $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{N}(\text{NO})\cdot\text{CH}_2\text{Ph}$, m. p. 69° , *α -nitroso- β -benzyl- α -methylhydrazine*, $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{NMe}\cdot\text{NO}$, m. p. 53° , and *α -nitroso- α -benzyl- β -methylhydrazine*, $\text{NHMe}\cdot\text{N}(\text{NO})\cdot\text{CH}_2\text{Ph}$, m. p. 39° , all of which give intense blue colorations with ferric chloride instead of the violet colorations obtained with monoalkylated nitrosohydrazines. Since the group $\cdot\text{N}\cdot\text{N}\cdot\text{OH}$ cannot be present in these four dialkylated nitrosohydrazines, it follows that this group is also not present in monoalkylated nitrosohydrazines, which therefore cannot have the symmetrical structure $\text{NHR}\cdot\text{NH}\cdot\text{NO}$, in which alone tautomerisation could occur in such a way as to form the group $\cdot\text{N}\cdot\text{N}\cdot\text{OH}$. α -Nitroso- β -benzyl- α -methylhydrazine and α -nitroso- α -benzyl- β -methylhydrazine exhibit very similar properties, but they depress each other's m. p., and the latter is changed into the former by mineral acids; the two substances are not identical, and consequently nitrosodialkylhydrazines cannot have the constitution

Fission into an amine and nitrogen monoxide has been accomplished hitherto only in nitrosohydrazines of the aromatic series. Now it is shown that members of the aliphatic series decompose in a similar manner, by heating nitrosobenzylhydrazine with ethyl oxalate; the resulting amine is isolated partly as *benzylloxamide*, $\text{NH}_2\cdot\text{CO}\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_5$, m. p. 223° , mainly as *ethyl benzylloxamate*, $\text{CO}_2\text{Et}\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_5$, m. p. 48° .

Sodium methylisooxazide, $\text{NMe}\cdot\text{N}\cdot\text{ONa}$, is obtained in slender, white needles by treating methyl-alcoholic nitrosomethylhydrazine with sodium methoxide, ether, and ethyl nitrite; it inflames when heated or when treated with concentrated sulphuric acid, explodes in moist carbon dioxide, yields diazomethane when heated at $130-200^\circ/12\text{ mm.}$, gives in aqueous or alcoholic solution a characteristic reddish-violet coloration with copper acetate, is reduced to methylhydrazine by 8–10% sodium hydroxide and aluminium, and is oxidised to methylnitroamino

by alkaline potassium ferricyanide. The isodiazomethane liberated from the sodium salt changes at once to diazomethane; thus, ordinary acids cause an evolution of nitrogen, benzoic acid produces methyl benzoate, hydrogen cyanide produces methylcarbamylamine, and β -naphthol produces β -naphthyl methyl ether. Sodium benzylisozoxide (*loc. cit.*) is unstable, decomposes in carbon dioxide, yields benzyl alcohol with dilute sulphuric acid, and benzyl β -naphthyl ether with β -naphthol, is reduced to benzylhydrazine by aluminium and 8% sodium hydroxide, and is oxidised by alkaline potassium ferricyanide to benzylnitroamine, $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{NO}_2$, m. p. 38—39°, which forms a mercury derivative, $\text{Hg}(\text{C}_6\text{H}_5\text{O}_2\text{N}_2)_2$.

s-Dibenzylhydrazine is best prepared by the cathodic reduction of a methyl-alcoholic solution of benzylideneazine containing potassium hydroxide; its dinitroso-derivative has m. p. 44°, and yields *s*-diphenylazomethane when gently warmed in the absence of air. *s*-Benzylmethylhydrazine dihydrochloride, $\text{NHMe}\cdot\text{NH}\cdot\text{CH}_2\text{Ph}\cdot 2\text{HCl}$, m. p. 140° (decomp.), is obtained by boiling either of the nitrosobenzylmethylhydrazines with concentrated hydrochloric acid.

s-Diphenylazomethane (*azotoluene*), $\text{CH}_2\text{Ph}\cdot\text{N}:\text{N}\cdot\text{CH}_2\text{Ph}$, m. p. 31.5°, is obtained by oxidising *s*-dibenzylhydrazine by 3% hydrogen peroxide and 20% ammonium hydroxide; it crystallises in colourless leaflets, and in alcoholic solution is converted into benzylidenebenzylhydrazone by a few drops of hydrochloric acid. In a similar manner, *s*-phenylbenzylhydrazine is oxidised to benzeneazophenylmethane, $\text{NPh}\cdot\text{N}\cdot\text{CH}_2\text{Ph}$, an orange-coloured oil which readily changes to benzaldehydophenylhydrazone, slowly at the ordinary temperature, rapidly at 200°.

C. S.

Formation of Hydrazones. UGO GRASSI (*Gazzetta*, 1910, 40, ii, 139—153).—The formation of menthonephenylhydrazone from menthone and phenylhydrazine in ethyl-alcoholic solution is complete; it is unimolecular, and the velocity is proportional to the quantity of acid present. In methyl alcohol the velocity is less. The formation of camphorphenylhydrazone could not be followed by the polarimetric method employed for the menthone derivative, but it was found possible to obtain indications that the reaction proceeds three hundred times more slowly than in the case of the latter, when the concentration of acid is the same.

A formula is worked out for the determination of reaction constants based on the measurement of the partition of the phenylhydrazine between two ketones, of which one is optically active. In the case of methyl propyl ketone, methyl isopropyl ketone, and pinacolin, compared in this way with menthone, the following relative reaction constants (K_2/K_1) were found respectively: 5.3, 2.71, 1.29. It follows that the branching of the carbon chain diminishes the readiness of formation of hydrazones.

The author has devised another method founded on the fact that the conductivity of an alcoholic solution of phenylhydrazine and an acid diminishes when phenylhydrazine is withdrawn from the liquid, so that from conductivity measurements it is possible to calculate the quantity of phenylhydrazine remaining in the solution at any time. The solu-

tions employed were 0.022*N* as regards the phenylhydrazine and the ketones, with 0.0065*N*-salicylic acid, and the observed conductivity ranged from 393 (initial) to 43 (final). The following are the reaction constants for the formation of phenylhydrazones of various ketones, the reactions being in all cases complete and unimolecular in the earlier stages: acetone, 0.122; methyl propyl ketone, 0.0228; methyl isopropyl ketone, 0.0114; pinacolin, 0.0043; benzaldehyde, 0.35; salicylaldehyde, 0.416; *m*-hydroxybenzaldehyde, 0.194; *p*-hydroxybenzaldehyde, 0.025; anisaldehyde, 0.061; protocatechualdehyde, 0.019; metocatechualdehyde carbonate, 0.123; piperonaldehyde, 0.048; anillin, 0.060; isovanillin, 0.048. Owing to the rapidity of the reactions, it was necessary to carry out the measurements at 10°. A simple thermostat is described convenient for this purpose, the low temperature being maintained by a supply of ice-water controlled by an electric thermoregulator.

R. V. S.

Derivatives of α -Amino-*n*-butyric Acid. ARNOLD HILDESHEIMER *ibid.*, 1910, 43, 2796—2805).— α -Phthalimino-*n*-butyric acid,

is readily formed when the corresponding ester (Gabriel and Colman, *Abstr.*, 1900, i, 359) is warmed with concentrated sulphuric acid for some three-quarters of an hour, and the mixture poured on to ice. It forms a resinous mass, which can be obtained in a crystalline form only with great difficulty, and then has m. p. 94—95°. The acid reacts with phosphorus pentachloride, yielding the corresponding acid chloride, which condenses with benzene in the presence of aluminium chloride, forming *phenyl phthaliminopropyl ketone*,

The ketone crystallises from light petroleum in colourless, six-sided plates, m. p. 118°, and on hydrolysis with hydrochloric acid yields *phenyl α -aminopropyl ketone hydrochloride*, $\text{NH}_2\cdot\text{CHEt}\cdot\text{COPh}\cdot\text{HCl}$, m. p. 178° after sintering at 170°. The *picrate* has m. p. 174° after sintering at 160°, and the *platinichloride* has m. p. 190—200° (decomp.).

3:6-Diphenyl-2:5-diethyl-2:5-dihydropyrazine,

is formed when an aqueous solution of phenyl aminopropyl ketone hydrochloride is mixed with ammonium hydroxide solution, the flask completely filled with air-free water, corked, and kept overnight. The *hydrochloride*, $\text{C}_{20}\text{H}_{20}\text{N}_2\text{Cl}$, forms a red, crystalline mass, m. p. 167—168° (decomp.).

The base and its hydrochloride are readily oxidised, even on exposure to the air; with dilute nitric acid, oxidation is instantaneous, and the product is Collet's 3:6-diphenyl-2:5-diethylpyrazine. On hydrolysis with hydrochloric acid in an atmosphere of carbon dioxide, the dihydro-base yields mainly phenyl α -aminopropyl ketone, with probably a small amount of the isomeric ketone, $\text{NH}_2\cdot\text{CHPh}\cdot\text{COEt}$ (compare Gabriel, *Abstr.*, 1908, i, 466).

Potassium thiocyanate reacts with an aqueous solution of phenyl aminopropyl ketone hydrochloride, yielding 2-thiol-5(or 4)-phenyl-4

in the form of snow-white needles, m. p. 273° after changing colour at 260° . Nitric acid oxidises the thiol to $\alpha\beta$ -phenylethylthiazole, $\text{C}_{11}\text{H}_{11}\text{N}_2$, m. p. 172° .

α -Phthaliminobutyric acid reacts with red phosphorus and bromine (compare Gabriel, Abstr., 1908, i, 182), yielding $\alpha\beta$ -dibromo- α -phthaliminopropane, $\text{C}_8\text{H}_5\text{O}_2\cdot\text{N}\cdot\text{CHBr}\cdot\text{CHMeBr}$, which crystallises from alcohol in well-developed octahedra, m. p. 147° . When boiled for an hour with water, the bromo-derivative yields phthrlimide, hydrogen bromide (1 mol.), and α -bromopropaldehyde according to the equation: $\text{C}_8\text{H}_5\text{O}_2\cdot\text{N}\cdot\text{CHBr}\cdot\text{CHMe} + \text{H}_2\text{O} = \text{C}_6\text{H}_4\text{O}_2 + \text{HBr} + \text{CHMeBr}\cdot\text{CHO}$. The α -bromopropaldehyde was identified by treatment with sodium acetate and then with phenylhydrazine, when Pinkus' acetolphenylhydrazone (Abstr., 1898, i, 224) was obtained. Hydroxyacetone can be prepared from aminoacetone hydrochloride by the action of nitrous acid, and Nef has shown that it is readily formed from α -hydroxypropaldehyde.

J. J. S.

Furoylacetic Ester and the Furylpyrazolones. III. HENRY A. TORREY and JOAQUIN E. ZANETTI (*Amer. Chem. J.*, 1910, 44, 5, 391—431. Compare Abstr., 1907, i, 146; 1908, i, 840).—The authors have studied the influence of the furyl group in ethyl furoylacetate and its pyrazolone derivatives, and have synthesised a new analogue of antipyrine containing the furyl group.

An improved method for preparing ethyl furoylacetate is described; the sodium and potassium salts were prepared; the oxime,

crystallises in long, white, silky needles, m. p. 131 — 132° . When hydroxylamine acts on ethyl furoylacetate in the presence of

crystallising in long, flat needles, m. p. 148 — 149° .

Ethyl furoylacetate forms a semicarbazone, which crystallises in small, flat, rhombic plates, and an oximino-derivative,

m. p. 128 — 129° . By the action of phenylcarbimide, ethyl furoylmalonanilate, $\text{C}_4\text{OH}_3\cdot\text{CO}\cdot\text{CH}(\text{CO}\cdot\text{NHPh})\cdot\text{CO}_2\text{Et}$, is produced, crystallising in white needles, m. p. 146 — 150° .

3-Furyl-5-pyrazolone, $\text{C}_4\text{OH}_3\cdot\text{C} \begin{array}{c} \text{N}=\text{NH} \\ \text{CH}_2\cdot\text{CO} \end{array}$, crystallises in small, rectangular plates, m. p. 223° (decomp.); its picrate decomposes at 192° . By the action of acetic anhydride on the pyrazolone, 1-aryl-3-furyl-5-pyrazolone, m. p. 153 — 154° , is obtained; the corresponding 1:2-diacetyl derivative forms long, silky needles, m. p. 103° .

Phenylcarbamylyl furylpyrazolone, $\text{C}_4\text{OH}_3\cdot\text{C} \begin{array}{c} \text{N}=\text{N} \\ \text{CH}_2\cdot\text{CO} \end{array} \text{N}\cdot\text{CO}\cdot\text{NHPh}$, m. p.

192° , is obtained by the action of phenylcarbimide on the pyrazolone,

and 4-benzyliden-3-furyl-5-pyrazolone, $\text{C}(\text{C}_4\text{OH}_3)=\text{N} \begin{array}{c} \text{C}(\text{CHPh})\cdot\text{CO} \end{array} \text{NH}$, by the

action of benzaldehyde. The azo-derivative, 4-benzeneazo-3-furyl-5-pyrazolone, crystallises in red, transparent prisms, m. p. 182—183°.

1-Phenyl-3-furyl-5-pyrazolone hydrochloride, $C_{13}H_{10}O_2N_2 \cdot HCl$, crystallises in small, white needles, m. p. 122—123°. By the action of acetic anhydride on 1-phenyl-3-furyl-5-pyrazolone, 2-acetyl-1-phenyl-3-furyl-

5-isopyrazolone, $C_{14}H_{12}O_2 \cdot C \cdot NAc$, $\begin{matrix} \text{CH}_2 \cdot \text{CO} > \text{NPh} \end{matrix}$, m. p. 69—72°, is obtained in small, flat, slightly yellow prisms. 5-Benzoyloxy-1-phenyl-3-furylpyrazole,

$C_{14}H_{12}O_3 \cdot C \cdot NPh$, $\begin{matrix} \text{CH} \cdot \text{C} > \text{NPh} \\ \text{CH} \cdot \text{C} > \text{OBz} \end{matrix}$, melts at 113—114°, and 4-oximino-1-phenyl-

3-furyl-5-pyrazolone, $C_{14}H_{12}O_3 \cdot C \cdot N$, $\begin{matrix} \text{OH} \cdot \text{N} \cdot \text{C} > \text{CO} \\ \text{CH} \cdot \text{C} > \text{NPh} \end{matrix}$, decomposes at 183—184°.

By the action of benzaldehyde on the pyrazolone, 4-benzylidene-1-phenyl-3-furyl-5-pyrazolone, decomposing at 210—212°, is obtained.

4-Benzeneazo-1-phenyl-3-furyl-5-pyrazolone, $C_{14}H_{12}O_2 \cdot C \cdot N$, $\begin{matrix} \text{N}_2\text{Ph} \cdot \text{CH} > \text{CO} \\ \text{CH}_2 \cdot \text{CO} > \text{NPh} \end{matrix}$, crystallises in long, light red needles, m. p. 165°.

4-β-Naphthaleneazo-1-phenyl-3-furyl-5-pyrazolone crystallises in deep, red needles, m. p. 202—203°. The hydriodide, m. p. 192—193°; the hydrochloride, m. p. 197—198°; the hydrobromide, m. p. 194°, and the picrate, m. p. 157—158°, of 1-phenyl-3-furyl-2-methyl-5-pyrazolone are described. 4-Nitroso-1-phenyl-3-furyl-2-methyl-5-isopyrazolone,

$C_{14}H_{12}O_2 \cdot C \cdot NMe$, $\begin{matrix} \text{NO} \cdot \text{C} > \text{CO} \\ \text{CH}_2 \cdot \text{CO} > \text{NPh} \end{matrix}$, crystallises in green needles, m. p. 185°; its hydrochloride crystallises in bright red needles, decomposing at 189°.

1-p-Bromophenyl-3-furyl-5-pyrazolone, $C_{14}H_{12}O_2 \cdot C \cdot N$, $\begin{matrix} \text{CH}_2 \cdot \text{CO} > \text{N} \cdot C_6H_4Br \end{matrix}$, prepared from p-bromophenyldiazine and ethyl furoylacetate, crystallises in needles, m. p. 160—161°.

3-Furyl-5-pyrazolone 1-benzene-p-sulphonic acid crystallises in small plates, turning brown when kept. 1-m-Nitrophenyl-3-furyl-5-pyrazolone crystallises in yellowish-brown prisms, m. p. 174—175°.

2-Phenyl-3-furyl-4-isopyrazolone, $C_{14}H_{12}O_2 \cdot C \cdot NPh$, $\begin{matrix} \text{CH} \cdot \text{CO} > \text{NH} \end{matrix}$, crystallises in transparent prisms, m. p. 176°.

N. C.

Quinazolines. XXV. Synthesis of 6- and 7-Amino-2-methyl-4-quinazolones from 4- and 5-Acetylaminoacetyl-anthranils. MARSTON T. BOGERT, CARL GUSTAVE ANEND, and VICTOR J. CHAMBERS (*J. Amer. Chem. Soc.*, 1910, 32, 1297—1312).—4- and 5-Acetylaminoacetyl-anthranils have been prepared by acetylating the corresponding tolylenediamines, oxidising the acetyl derivatives with a neutral solution of potassium permanganate, and treating the resulting diacetylamino benzoic acids with excess of acetic anhydride. The oxidation of 2:5-diacetylamino-toluene proved much more difficult than that of the 2:4 compound, and gave a much smaller yield of the diacetylamino benzoic acid.

When these acetylaminoacetyl-anthranils are condensed with primary

amines, acetylamino-4-quinazolones are produced, and, on eliminating the acetyl group, the 6- or 7-amino-2-methylquinazolones are obtained. Nearly all the quinazolones now described are crystalline solids of high m. p. or b. p.

4-Acetylaminoacetylanthranil, $\text{NHAc} \cdot \text{C}_6\text{H}_3 \begin{smallmatrix} \text{CO} \\ \diagup \\ \text{N} \end{smallmatrix} \text{Ac}$, m. p. 220° (corr.), crystallises in colourless needles. 2:5-Diacetylamino-2-oxo-1,4-benzodiazepine-3-carboxylic acid, $\text{C}_6\text{H}_3(\text{NHAc})_2 \cdot \text{CO}_2\text{H}$, m. p. 263° (decomp., corr.), forms minute, colourless crystals. 5-Acetylaminoacetylanthranil, m. p. 253° (corr.), crystallises in needles. The 4- and 5-acetylaminoacetylanthranils absorb moisture, and are re-converted into the corresponding diacetylamino-2-oxo-1,4-benzodiazepine-3-carboxylic acids.

The following quinazolones were prepared from 4-acetylaminoacetylanthranil. 7-Acetylamino-2-methyl-4-quinazolone (4-hydroxy-7-acetylamino-2-methylquinazoline),

m. p. 344° (corr.), crystallises in slender, silky needles, containing $2\text{H}_2\text{O}$, and when boiled with dilute potassium hydroxide is converted into 7-amino-2-methyl-4-quinazolone (Eger and Kläber, Abstr., 1908, i, 466). The latter compound does not react with phenylhydrazine or ethyl chloroacetate; when boiled with formaldehyde and potassium cyanide, a reaction takes place, but the product does not contain any new substances; its potassium salt, hydrochloride, and platinumchloride are described.

Dinitro-7-acetylamino-2-methyl-4-quinazolone, m. p. 302° (decomp.), forms orange crystals; the nitro-groups probably occupy the 6- and 8-positions. Bromo-7-acetylamino-2-methyl-4-quinazolone, m. p. 292° (corr.), crystallises in minute needles, and, when boiled with 10% potassium hydroxide solution, is converted into bromo-7-amino-2-methyl-4-quinazolone, m. p. 272° — 273° (corr.), which forms light yellow, flaky crystals. 7-Formylamino-2-methyl-4-quinazolone, m. p. 329° — 340° (corr.), forms colourless, feathery crystals, and the corresponding propionyl derivative, m. p. 326° — 327° (corr.), crystallises in long, white, silky needles. When a solution of 7-amino-2-methyl-4-quinazolone in dilute hydrochloric acid is treated with sodium nitrite at 0° and the product boiled and afterwards neutralised with sodium carbonate,

a light brown powder, which darkens at about 345° , but does not melt at this temperature; its acetyl derivative, m. p. 266° (corr.), forms large, pale brown needles. If the diazotisation product of 7-amino-2-methyl-4-quinazolone is boiled with a solution of copper potassium

303° — 304° (corr.), is produced, which crystallises in colourless, feathery needles.

m. p. 281° (corr.), obtained by the action of methylamine on 4-acetylaminoacetylthranil, forms colourless, silky needles. 7-Amino-2:3-dimethyl-4-quinazoline, m. p. 224° (corr.), crystallises in needles or prisms; its *platinichloride* is described. 7-Acetylamino-2-methyl-3-ethyl-4-quinazoline, m. p. 254° (corr.), forms short, colourless needles or lustrous plates. 7-Acetylamino-2-methyl-3-n-propyl-4-quinazoline, m. p. $206-207^{\circ}$ (corr.), crystallises in rosettes of needles. 4-Acetylaminoacetylthranil does not undergo condensation with *sec.*-butylamine, but yields 2:4-diacetylamino-*benzo-sec.-butylamide*,

m. p. 235° (corr.), which forms colourless needles. 7-Acetylamino-2-methyl-3-isoamyl-4-quinazoline has m. p. 288° (corr.), and the corresponding 3-phenyl, 3-p-anisyl, 3-p-phenetyl, and 3- α -naphthyl derivatives have m. p. 276° , 273° , 259° , and 256° (corr.) respectively. When 4-acetylaminoacetylthranil is heated with *p*-aminobenzonitrile, a quinazoline is not produced, but a compound, m. p. 258° (corr.), is obtained, containing 12.4% of nitrogen.

When hydrazine hydrate (1 mol.) is boiled with 4-acetylaminoacetylthranil (1 mol.), 3-amino-7-acetylamino-2-methyl-4-quinazoline, m. p. 268° (corr.), is produced, which crystallises with $1\text{H}_2\text{O}$, and fails to give the Bülow condensation (Abstr., 1906, i, 906, 981) with ethyl diacetylsuccinate; the *hydrochloride* has m. p. 312° (decomp.). If 4-acetylaminoacetylthranil is treated in the cold with 50% hydrazine hydrate solution, 2:4-diacetylamino-*benzoylhydrazide*,

is produced, which crystallises in short, slender needles, and melts at 268° with formation of 7-acetylamino-3-amino-2-methyl-4-quinazoline. 3:7-Diacetylamino-2-methyl-4-quinazoline, m. p. 304° (corr.), forms minute, colourless crystals, and, when boiled with dilute potassium hydroxide, is converted into 3:7-diamino-2-methyl-4-quinazoline, m. p. 238° (corr.), which forms silky needles.

3-Anilino-7-acetylamino-2-methyl-4-quinazoline,

m. p. 214° (corr.), obtained by the action of phenylhydrazine on 4-acetylaminoacetylthranil, forms colourless, feathery needles.

7-Acetylamino-2-methyl-4-quinazolonyl-3:7-(2'-methyl-4'-quinazoline),

n. p. 335° (corr.), obtained by the condensation of 7-amino-2-methyl-4-quinazoline with 4-acetylaminoacetylthranil, crystallises in short, stout, pale yellow needles.

The following quinazolones were prepared from 5-acetylaminoacetylthranil. 6-Acetylamino-2-methyl-4-quinazolone, m. p. 350° (corr.), forms colourless needles or prisms. 6-Amino-2-methyl-4-quinazolone, m. p. $314-315^{\circ}$ (corr.), crystallises in rosettes of needles. 7-Acetylamino-2:3-dimethyl-4-quinazolone, m. p. 278° (corr.), and 7-acetylamino-2-methyl-3-ethyl-4-quinazolone, m. p. 229° (corr.), form colourless, silky needles. The corresponding 3-n-propyl and 3-phenyl

derivatives have m. p. 181° and 255° (corr.) respectively. 3-Amino-6-acetylamino-2-methyl-4-quinazoline, m. p. 262° — 263° (corr.), obtained by heating 5-acetylaminoacetylanthranil with dilute hydrazine hydrate, crystallises in rosettes of colourless, silky needles.

E. G.

Diguanide and Compounds Derived from It. KAROL RACKMANN (*Annalen*, 1910, 376, 163—183. Compare Bamberger and Dieckmann, *Abstr.*, 1892, 737; Söll and Stutzer, this vol., i, 14).—Diguanide has been prepared by a modification of Herth's method (*Abstr.*, 1881, 896), using soda-water bottles in place of sealed tubes. The sulphate can be obtained from the copper derivative by treatment with 10% sulphuric acid, and the free base from the sulphate by the action of barium hydroxide. Diguanide, $\text{NH}[\text{C}(\text{NH}_2)_2\text{NH}]_2$, crystallises from absolute alcohol in glistening prisms, m. p. 130° , and its aqueous solution decomposes gradually when kept. The carbonate, $\text{C}_2\text{H}_2\text{N}_7\text{H}_2\text{CO}_3$, crystallises in prisms, sparingly soluble in alcohol; the normal hydrochloride, $\text{C}_2\text{H}_2\text{N}_7\text{HCl}$, forms glistening needles, m. p. 235° , and the acid hydrochloride, $\text{C}_2\text{H}_2\text{N}_7\cdot 2\text{HCl}$, large plates, m. p. 248° . The nitrate, $\text{C}_2\text{H}_2\text{N}_7\text{HNO}_3$, crystallises in large, glistening prisms, m. p. 192° ; the acetate, $\text{C}_2\text{H}_2\text{N}_7\text{CH}_3\text{CO}_2\text{H}$, has m. p. 268° , the oxalate, $\text{C}_2\text{H}_2\text{N}_7\text{C}_2\text{O}_4\text{H}_2$, m. p. 210° , and the chloroacetate, m. p. 186° . The cyanoacetate forms soluble, glistening plates, and the succinate, $2\text{C}_2\text{H}_2\text{N}_7\text{C}_2\text{H}_4(\text{CO}_2\text{H})_2$, colourless crystals.

Oxalyldiguanide, $\begin{array}{c} \text{CO}\cdot\text{NH}\cdot\text{C}(\text{NH}) \\ \text{CO}\cdot\text{NH}\cdot\text{C}(\text{NH}) \end{array} \rangle \text{NH}$, prepared by the action of ethyl oxalate on diguanide, crystallises from alcohol in large, colourless needles, which decompose above 300° . It does not react with ethyl oxalate or ethyl malonate, but when warmed with dilute hydrochloric acid yields diguanidino-oxalic acid,

which crystallises in long, thin needles, m. p. 240° . The sodium salt, $\text{C}_4\text{H}_6\text{O}_8\text{N}_5\text{Na}$, forms long needles, and the barium salt, small, sparingly soluble needles.

Malonyldiguanide (4 : 6-diketo-2-guanidinopyrimidine),

prepared by boiling an alcoholic solution of diguanide with ethyl malonate, crystallises in small needles, and has not acidic properties. The hydrochloride, $\text{C}_6\text{H}_6\text{O}_2\text{N}_5\text{HCl}$, forms feathery needles, and the sulphate, $2\text{C}_6\text{H}_6\text{O}_2\text{N}_5\cdot\text{H}_2\text{SO}_4$, large needles. *Succinyldiguanide*,

is only formed in the absence of all traces of water, and has feebly basic properties. The sulphate, $\text{C}_6\text{H}_6\text{O}_2\text{N}_5\cdot\text{H}_2\text{SO}_4$, crystallises in large needles, the hydrochloride, $\text{C}_6\text{H}_6\text{O}_2\text{N}_5\cdot 2\text{HCl}$, in slender needles, and the picrate, $\text{C}_6\text{H}_6\text{O}_2\text{N}_5\cdot\text{C}_6\text{H}_3\text{O}_7\text{N}_3$, in brilliant, large needles, m. p. 220° .

A theoretical yield of ammeline can be obtained by condensing diguanide with an absolute alcoholic solution of ethyl carbonate, and a theoretical yield of thioammeline by condensing diguanide with an alcoholic solution of hydrogen sulphide. The symmetrical constitu-

tional formulae for these two compounds are regarded as established beyond dispute by these syntheses, and also the symmetrical formulae of other cyanuric acid derivatives.

When diguanide is condensed in aqueous solution with carbon disulphide, the product consists of somewhat unstable, reddish-brown crystals, $C_3H_5N_9S_2$.

Formylguanamine (1:3-diamino-1:3:5-triazine) (Bamberger and Dieckmann: Abstr., 1892, *loc. cit.*) can be synthesised from diguanide and ethyl formate in absolute alcoholic solution.

Phenylguanamine (3:5-diamino-1-phenyl-1:3:5-triazine),

prepared by the action of benzoyl chloride and alkali on diguanide sulphate, crystallises from water in large prisms, m. p. 222° , and yields a picrate, m. p. 228° .

Diguanide reacts with an alcoholic solution of chloroacetic acid, yielding diguanidinouacetic acid, $C_3H_6N_3 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$, in the form of its hydrochloride. The acid crystallises from aqueous alcohol in long needles, and reacts with both acids and alkalis. The sodium salt, $C_3H_5O_2N_3Na$; hydrochloride, $C_3H_5O_2N_3 \cdot \text{HCl}$, and picrate,

m. p. 202° , are described.

J. J. S

Synthesis of Tetrazoles from Arylazoiimides. OTTO DIMROTH and SIEGFRIED MERZBACHER (*Ber.*, 1910, 43, 2899—2904. Compare Abstr., 1907, i, 659).—Extending to acetaldehydophenylhydrazone and glyoxylic acid phenylhydrazones the reaction with phenylazoiimide previously studied, the authors have been able to isolate *N*-benzeneazacetophenylhydrazidine, $\text{NHPh} \cdot \text{N} \cdot \text{N} \cdot \text{CMe} \cdot \text{N} \cdot \text{NHPh}$ or

and *N*-benzeneazo-oxalophenylhydrazidine,

as intermediate products. The former substance when treated with hydrochloric acid yields benzenediazonium chloride and acetophenylhydrazidine, $\text{CMe}(\text{NH}_2) \cdot \text{N} \cdot \text{NHPh}$. The second product cannot be decomposed in that way, but benzeneazo-5-hydroxy-1-phenyl-1:2:3-triazole (compare Dimroth and Eberhardt, Abstr., 1905, i, 99) is formed when its sodium salt is treated with benzoyl chloride and sodium hydroxide. These hydrazidine derivatives could not be converted into tetrazoles. When, however, tribromophenylazoiimide reacts with the hydrazones mentioned, the intermediate products are labile; they lose tribromoaniline spontaneously, 1-phenyl-4-methyl-1:2:3:5-tetrazole and 1-phenyl-1:2:3:5-tetrazole-4-carboxylic acid being obtained.

N-Benzeneazacetophenylhydrazidine, obtained by heating acetaldehydophenylhydrazone and phenylazoiimide in alcoholic sodium ethoxide solution for forty hours on the water-bath, crystallises in reddish-yellow, rhomboidal tablets, m. p. 101° (with evolution of gas). In contact with dilute hydrochloric acid, it gradually dissolves with evolution of gas, and from the solution acetophenylhydrazidine hydrochloride, $C_8H_{12}N_3Cl \cdot \frac{1}{2}\text{H}_2\text{O}$, can be obtained (compare

Voswinckel, Abstr., 1902, i, 844). It melts at 140° , resolidifies, and melts again (not sharply) at 205° .

The sodium salt of *N*-benzenazo-oxalomonophenylhydrazidine,
 $C_{14}H_{12}O_2N_5Na \cdot 3H_2O$,

is prepared by heating glyoxylic acid phenylhydrazone and phenylazimidide in alcoholic sodium ethoxide solution for fifteen minutes on the water-bath. It is a yellow, crystalline substance, which becomes red in excess of sodium hydroxide in consequence of the formation of a disodium salt. With acids, it yields the free acid as a flocculent precipitant, which soon decomposes with evolution of gas even in the cold.

1-Phenyl-4-methyl-1:2:3:5-tetrazole, $PhN \cdot N \cdot N \cdot CMe \cdot N$, is best freed from the accompanying tribromoaniline by extraction with ether and subsequent distillation in a vacuum, the distillate being collected at $140^{\circ}/15$ mm. It crystallises in long, flat, colourless needles, m. p. 40° , and has an odour of jasmine, although the isomeric 1-phenyl-5-methyl-1:2:3:4-tetrazole (following abstract) has no smell.

R. V. S.

Diazohydrazides. OTTO DIMROTH and GUILLAUME DE MONTMOLIN (*Ber.*, 1910, 43, 2904—2915. Compare preceding abstract).—The diazohydrazides from monoacylhydrazines condense to 1:2:3:4-tetrazoles when treated with alkalis, indicating that they are β -diazohydrazides of the type $NAr \cdot N \cdot NH \cdot NH \cdot CO \cdot R$ (compare Curtius, Abstr., 1893, i, 463). The diazo-derivatives of the diacylhydrazines, also yield tetrazoles with alkalis, an acyl group being eliminated, and in many cases (for example, 5-hydroxy-1-phenyltetrazole) this synthesis offers the best means of preparing tetrazole derivatives. It was not found possible to prepare the bisdiazohydrazides,
 $NAr \cdot N \cdot NAc \cdot NAc \cdot N \cdot NAr$,

from which pentazoles might have been obtained by a method analogous to that described in the preceding abstract. Only monoacyl-diazohydrazides can react with a second molecule of a diazonium salt, and they then undergo a tautomeric rearrangement, such that the reaction product spontaneously decomposes into the diazoamide-compound and the azoimide of the acid group.

Diacylhydrazines do not react with diazonium salts in acid solution. The diazohydrazides are readily obtained as white or yellow, usually flocculent, precipitates, however, when aqueous solutions of the diacylhydrazides are treated with a slight excess of sodium carbonate, and then with the equivalent quantity of the neutralised diazonium chloride solution. The temperature is maintained at -10° , salt being added to prevent freezing. On addition of sodium hydroxide, the precipitate is converted into the tetrazole derivative. 1-Phenyl-1:2:3:4-tetrazole was obtained by the use of diformylhydrazine (the diazohydrazide from which is very unstable), and it has the properties formerly described. 1-*p*-Tolyl-1:2:3:4-tetrazole, $C_6H_5N_4$, forms colourless needles, m. p. 96° . 1-*p*-Nitrophenyltetrazole may be obtained similarly.

1-Phenyl-5-methyl-1:2:3:4-tetrazole, $NPh \cdot N \cdot N \cdot CMe$ (from

diacetylhydrazine), forms lanceolate crystals, m. p. 97.5° . *p*-Toluenesulphohydrazine, $C_7H_7N_2 \cdot NAc \cdot NHAc$, is more stable than the phenyl derivative. It forms small, pale brown crystals, m. p. 60° (decomp.). 1-*p*-Tolyl-5-methyl-1:2:3:4-tetrazole, $C_8H_{10}N_4$, has m. p. 106° . *p*-Nitrobenzenesulphohydrazine, $C_{10}H_{11}O_3N_5$, forms colourless, lustrous crystals, m. p. 107° (with evolution of gas). It can be preserved unchanged in the dry state for months. 1-*p*-Nitrophenyl-5-methyl-1:2:3:4-tetrazole, $C_8H_7O_2N_5$, crystallises in pale yellow plates, m. p. 129° .

The diazohydrazides from dibenzoylhydrazine are more unstable than those from diacetylhydrazine. It is necessary to dissolve the hydrazine in dilute sodium hydroxide, owing to its slight solubility in water. Benzenesulphobenzoylhydrazine was obtained as a white, unstable precipitate.

5-Hydroxy-1-phenyl-1:2:3:4-tetrazole, obtained from ethyl hydrazinedicarboxylate and benzenediazonium chloride, is identical with the phenylhydroxytetrazole of Freund and Hempel (Abstr., 1895, i, 133).

Tribromobenzenediazonium salts react (but incompletely) with ethyl hydrazinedicarboxylate in weakly acid solution. Ethyl tribromobenzenesulphohydrazinedicarboxylate, $C_6H_2Br_3N_2 \cdot N(CO_2Et) \cdot NH \cdot CO_2Et$, is better obtained in presence of sodium carbonate. It forms small, colourless needles, which explode at $111-115^{\circ}$, according to the rate of heating. The compound can be preserved unchanged. Ethereal hydrogen chloride decomposes it into its components. It was not possible to prepare the corresponding tetrazole.

The monoacylhydrazines react with diazonium salts, not only in alkaline, but also in acid solution. Most of the diazohydrazides are too unstable to be isolated and purified. Benzenesulphohydrazide and *p*-toluenesulphohydrazide are white precipitates, which are rapidly converted into the tetrazoles when treated with sodium hydroxide. *p*-Nitrobenzenesulphohydrazide, $NO_2 \cdot C_6H_4 \cdot N_2 \cdot NH \cdot NHAc$, is soluble in dilute sodium hydroxide with production of an intense, bluish-red coloration, which afterwards disappears, and the tetrazole is formed. With *p*-toluenediazonium chloride in solution containing alkali hydroxide, it yields *p*-nitrobenzenediazoaminotoluene (Bamberger, Abstr., 1895, i, 351), a smell of *p*-tolylazoinide is observed, and azoinide is found in the filtrate. Sulphobenzenesulphohydrazide, $SO_3H \cdot C_6H_4 \cdot N_2 \cdot NH \cdot NHAc$, is obtained by the method described in the form of its sodium salt, which is very stable when dry. Water slowly effects an anomalous decomposition, azoinide and sodium sulphinate being produced. The substance reacts with *p*-toluenediazonium chloride only in the presence of sodium hydroxide, azoinide and sodium *p*-toluenediazoaminobenzenesulphonate being formed. With sodium hydroxide the diazohydrazide yields the sodium salt of 1-phenyl-5-methyl-1:2:3:4-tetrazolesulphonic acid,

in crystalline form. The silver salt, $C_8H_7O_3N_4SAg$, crystallises in flat, lustrous prisms.

Benzenesulphobenzhydrazide (Curtius, loc. cit.) is converted by sodium

hydroxide into 1:5-diphenyl-1:2:3:4-tetrazole, identical with that of Schröter (Abstr., 1909, i, 617, 773).

5-Phenyl-1-*p*-nitrophenyl-1:2:3:4-tetrazole, $C_{13}H_9O_2N_5$, is produced in addition to *p*-nitrophenylazoimide and a green sodium salt, *rac*-*p*-nitrobenzeneazohenzhydrazide (von Pechmann, Abstr., 1896, i, 615), is dissolved in sodium hydroxide. It forms yellow prisms, m. p. 149°. The nitrophenylphenyltetrazole, m. p. 177—178°, obtained by Schröter must therefore have the structure:

Semicarbazide reacts with benzene and with *p*-toluene-diazonium chlorides in acetic acid solution, yielding crystalline diazohydrazides. The *toluene* derivative is the more stable. It forms colourless laminae, which decompose rapidly even when dry. An ethereal solution, when kept in the cold, deposits carbamazoimide of m. p. 97°, and in the filtrate *p*-toluidine is present. Tolueneazosemicarbazide does not yield the corresponding tetrazole when treated with alkali. The action of a cold alcoholic solution of sodium ethoxide gives rise to sodium azoimide, diazoaminotoluene, *p*-toluidine, and sodium carbonate. Hence it is possible that in this diazohydrazide the azo-group is attached in the α -position.

R. V. S.

Action of Diazo-compounds on Ethyl Glutaconate. FRIEDRICH HENRICH, W. REICHENBURG, G. NACHTIGALL, W. THOMAS, and C. BAUM (Annalen, 1910, 376, 121—151. Compare Abstr., 1899, i, 764; Dimroth and Hartmann, Abstr., 1909, i, 66).—The products obtained by the action of diazonium salts (1 mol.) on ethyl glutaconate are yellow, and have the constitution of azo-compounds, for example,

or the tautomeric hydrazone formula,

The fact that they can be boiled with alcohol or even distilled without decomposition and that they do not couple with R-salt indicates that they cannot have the diazo-constitution $>\text{C}(\text{OEt})\cdot\text{O}\cdot\text{N}_2\text{R}$ (compare Dimroth, *loc. cit.*), although it is highly probable that such diazo-compounds are formed as unstable intermediate products in the preparation of the stable azo-compounds.

The condensation takes place most readily in an aqueous alcoholic solution of the ester, and in the presence of sodium acetate and aqueous solution of the diazonium salt. The reaction proceeds slowly and is complete in half to one hour.

When an excess of diazonium salt is used, a compound of the type $\text{CO}_2\text{Et}\cdot\text{C}(\text{N}_2\text{Ph})\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{N}\cdot\text{NHPh}$ is formed. These compounds are quite different from the formazyl derivatives described previously (Heimich and Thomas, Abstr., 1908, i, 114); they have an intense red colour, and readily lose the elements of ethyl alcohol when heated in alcohol, yielding pyridazone derivatives:

decomposition proceeds at very different rates with the different condensation products, those containing ortho-substituents in the mesene nuclei being most stable. When such substituents are present, the elimination of the alcohol is effected by heating with acetic anhydride, but in the case of the mesitylene derivative, even this reagent is without action. The stability of the compounds depends not merely on the positions of the substituents, but also on their chemical nature, the more electro-positive the ortho-substituent the greater its stabilising effect. The pyridazone derivatives are brown or brownish-yellow solids, the colour being palest when halogen substituents are present in *m*- or *p*-positions; they are stable towards organic acids or aqueous solutions of alkalis, but dissolve in concentrated phosphoric acid, yielding reddish-yellow solutions.

Ethyl glutaconate phenylhydrazone,

(desmotropic formula), separates from alcohol in long, pale yellow, glistening crystals, *m. p.* 67–68°. *Ethyl 3-benzeneazoglutaconate phenylhydrazone*, $\text{N}_2\text{Ph}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{N}\cdot\text{NHPh}$, separates in a boiling mixture of benzene and light petroleum (1:4) in brilliant, glistening, rhombic crystals [*a*:*b*:*c* = 0.4423:1:0.6561], *m. p.* 117° (decomp); it gives Bulow's reaction, and is decomposed to a certain extent when boiled for some time with benzene. *Ethyl 3-benzeneazo-1-phenyl-6-pyridazone-3-carboxylate*,

crystallises from alcohol in brownish-yellow needles, *m. p.* 161°.

Ethyl 3-o-toluenazoglutaconate o-tolylhydrazone,

forms dark red, glistening crystals, *m. p.* 131°, after sintering at 130°, the corresponding *ethyl 5-o-toluenazo-1-o-tolyl-6-pyridazone-3-carboxylate*, $\text{C}_{21}\text{H}_{20}\text{O}_5\text{N}_4$, crystallises in dark brown needles, *m. p.* 160°, after sintering at 150°; the isomeric *5-p-toluenazo-1-p-tolyl-6-pyridazone-3-carboxylate* forms pale brown-coloured needles, *m. p.* 157°, and is precipitated readily from *ethyl 3-p-toluenazoglutaconate p-tolylhydrazone*, $\text{H}_3\text{C}\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{N}\cdot\text{N}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{N}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{H}_3\text{C}$, which resembles the ortho-compound, and has *m. p.* 131°, after sintering at 120°.

*Ethyl 3-benzeneazoglutaconate *as*-m-xyllylhydrazone*,

crystallises from dilute alcohol in pale yellow, glistening needles, *m. p.* 107°. *Ethyl m-xyleneazoglutaconate m-xyllylhydrazone*, $\text{C}_6\text{H}_3\text{Me}_2\cdot\text{N}\cdot\text{N}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})\cdot\text{N}\cdot\text{NH}\cdot\text{C}_6\text{H}_3\text{Me}_2$, crystallises in glistening prisms, *m. p.* 160–161°.

Ethyl 3-mesityleneazoglutaconate 3-carboxylate,

crystallises from alcohol in brilliant, brown prisms, *m. p.* 155° after sintering at 140°. *Ethyl glutaconate mesitylhydrazone*,

crystallises from dilute alcohol in yellow, glistening crystals, *m. p.* 80°. *Ethyl 3-mesityleneazoglutaconate mesitylhydrazone*,

JL. XCV

i.

separates from light petroleum in glistening, red crystals, m. 143—150°, and does not yield a pyridazone derivative. *Ethyl glutacononate o-phenethylhydrazone*,

forms glistening, yellow crystals, m. p. 85°, and *ethyl o-phenethylhydrazonate o-phenethylhydrazone*,

crystallises from benzene in dark red, glistening prisms, m. p. 145°.

Ethyl p-chlorobenzeneazoglutacononate p-chlorophenethylhydrazone,

crystallises in orange-coloured prisms, m. p. 138°, and when heated with alcohol yields *ethyl 5-p-chlorobenzeneazo-1-p-chlorophenyl-6-pyridazone-3-carboxylate*, $\text{C}_{17}\text{H}_{11}\text{O}_4\text{N}_4\text{Cl}_2$, as pale brown needles, m. p. 208—210°, after sintering at 205°. *Ethyl 3-m-bromobenzeneazoglutacononate m-bromophenethylhydrazone*, $\text{C}_{21}\text{H}_{19}\text{O}_4\text{N}_4\text{Br}_2$, also forms orange-coloured crystals, and has m. p. 130°; *ethyl 5-m-bromobenzeneazo-1-m-bromophenyl-6-pyridazone-3-carboxylate*, $\text{C}_{19}\text{H}_{13}\text{O}_4\text{N}_4\text{Br}_2$, forms pale brown microscopic needles, m. p. 149°. The isomeric o-bromo-derivatives of the glutacononate and pyridazone compounds melt respectively at 143—144° and 166—167°, and the p-bromo-derivatives at 146 and 229°.

Ethyl glutacononate p-nitrophenethylhydrazone,

forms a yellow, crystalline powder, m. p. 109°.

Formyl-α-methylacrylic acid, $\text{NHPh}\cdot\text{N}\cdot\text{C}(\text{N}\cdot\text{NPh})\cdot\text{CH}\cdot\text{CO}_2\text{H}$, is formed by the action of benzenediazonium chloride (2 mol.) on methylglutaconic acid in dilute acetic acid solution (compare Abstr. 1908, i, 114), and crystallises from alcohol in dark-coloured needles, m. p. 193° (decomp.). It yields a sparingly soluble, reddish-brown, silver salt.

J. J. S.

Decomposition of Azopyrazolones by means of Concentrated Nitric Acid. CARL BÜLOW, KARL HAAS, and, in part, with H. SCHMACHTENBERG (*Ber.*, 1910, 43, 2647—2662).—Rothemann's 4-benzeneazo-3-methyl-5-pyrazolone (Abstr., 1895, i, 687) can be prepared by the condensation of hydrazine hydrate with ethyl phenylazoacetate in acetic acid solution. Nitric acid reacts with this pyrazolone, yielding first an additive compound, $\text{C}_{10}\text{H}_{10}\text{ON}_4\cdot\text{HNO}_3$, and finally an orange-yellow nitro-derivative, which has been shown to be 4-p-nitrobenzeneazo-3-methyl-5-pyrazolone, as it can be decomposed from ethyl p-nitrophenylazoacetate and hydrazine hydrate. Further reaction with nitric acid decomposes the nitro-derivative into Betti's 4-nitro-3-methyl-5-pyrazolone (Abstr., 1907, i, 533) and benzenediazonium nitrate. This decomposition proceeds according to the equation: $\text{C}_{10}\text{H}_{10}\text{ON}_4 + 2\text{HNO}_3 = \text{N}_2\text{PhNO}_2 + \text{C}_7\text{H}_5\text{O}_2\text{N}_3$, is used in favour of the azo-structure of the original compound, since Schmidt (Abstr., 1905, i, 951) has shown that true azo-dyes react with concentrated nitric acid, yielding the same compound used in the preparation of the dye, and a nitro-derivative of the compound, which was "coupled" with the diazo-solution.

suggestion that the azo-derivatives of pyrazolone are hydrazones is thus incorrect.

Similarly, the products obtained by the action of diazonium salts on 4-substituted isooxazolones (Claisen and Zedel, Abstr., 1891, 468) are azo-derivatives (*o*-hydroxyazo-compounds), as they are decomposed by nitric acid in acetic acid solution, yielding a diazonium nitrate and a nitro-derivative of the isooxazolone, for example:

Knorr's 4-nitro-1-phenyl-3-methyl-5-pyrazolone (Abstr., 1887, 601) and Betti's 4-nitro-3-methyl-5-pyrazolone are represented by hydroxylic and not ketonic formula; for example, the latter as

since the hydroxylic structure accounts for the pronounced acidic character of these nitro-compounds; for example, their alkali salts are neutral.

The primary product of the condensation of ethyl phenylazoacetate and hydrazine hydrate in cold glacial acetic acid crystallises in glistening, red needles, m. p. 167°; when boiled with alcohol or glacial acetic acid it yields 4-benzeneazo-3-methyl-5-pyrazolone; when boiled with an acetic acid solution of phenylhydrazine it yields 4-benzeneazo-1-phenyl-3-methylpyrazolone, and when heated for a few minutes with an 80% acetic acid solution of benzhydrazide it yields ethyl phenylazoacetate benzoylhydrazone, m. p. 146°. All these reactions indicate that the red compound is to be represented as $\text{N} \cdot \text{H} \cdot \text{CMe} \cdot \text{C}(\text{N}_2\text{Ph}) \cdot \text{CO}_2\text{Et}$.

1-Nitro-5-hydroxy-3-methylpyrazole (4-nitro-3-methyl-5-pyrazolone) crystallises from acetic acid in prisms, m. p. 267° (decomp.), but cannot be acetylated. Its alkali salts are neutral, and hence the hydroxy-compound can be titrated by means of a standard alkali hydroxide solution, using phenolphthalein as indicator. The following salts are described: *potassium*, $\text{C}_4\text{H}_4\text{O}_2\text{N}_3\text{K}$; *ammonium*, yellow needles, decomposing at 248°; *hydrazine*, $\text{C}_4\text{H}_5\text{O}_2\text{N}_3 \cdot \text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$, glistening, yellow needles; *barium*, long, golden-yellow, compact prisms; *zinc*, yellow needles; *aluminium*, slender, yellow needles; *silver*, yellow plates, and also *copper*, *lead*, *cobalt*, and *nickel* salts.

4-Benzeneazo-5-hydroxy-3-methylpyrazole reacts with aqueous nitrous acid, yielding 4-benzeneazo-1-nitroso-5-hydroxy-3-methylpyrazole, $\text{NPh} \cdot \text{N} \cdot \text{C} \begin{array}{c} \text{C}(\text{OH}) \cdot \text{N} \cdot \text{NO} \\ \text{CMe} = \text{N} \end{array}$, which crystallises in slender

needles, decomposing at 135°. The nitroso-group can be eliminated by warming for a short time with dilute sodium hydroxide solution, with 15% hydrochloric acid, yielding the original hydroxypyrazole. The nitroso-compound is also decomposed when boiled with alcohol, acetic, or glacial acetic acid, and reacts with an excess of nitrous acid, yielding as final product 2:4-dinitrophenol.

When reduced with stannous chloride and hydrochloric acid 4-benzeneazo-5-hydroxy-3-methylpyrazole yields aniline and 4-amino-3-methylpyrazole, but the latter cannot be isolated on

account of the readiness with which it undergoes oxidation into a homologue of rubazonic acid, m. p. 238°.

The same acid is formed, together with a stable product, $C_6H_6O_2N_2$, by the action of oxidising agents on the reduction product of 4-nitro-5-hydroxy-3-methylpyrazole.

4-*m*-Xyleneazo-5-hydroxy-3-methylpyrazole also reacts with nitric acid, yielding 4-nitro-3-methylpyrazolone and *m*-xylenediazonium nitrate.

Nitric acid reacts with ethyl phenylazoacetoacetate, yielding ethyl *p*-nitrophenylazoacetoacetate.

J. J. S.

Monosubstituted Triazens and Attempts to Prepare Triazen. OTTO DIMROTH and KARL PFISTER (*Ber.*, 1910, 43, 2757—2767).—By the reduction of phenylazoisimide by stannous chloride in ethereal solution, phenyltriazene is obtained (Dimroth, *Abstr.*, 1907, i, 653). The reaction has been extended to substituted azides, some few of which are more stable than phenyltriazene, but the majority are less stable, decomposing on formation into amine and nitrogen. Benzylazoisimide is much less easily reduced than phenylazoisimide, and the triazen decomposes immediately on formation.

Attempts to reduce azoisimide to triazen by a variety of methods were without success, but it is believed that triazen can exist for a short time in aqueous solution at -10° .

The reductions were carried out at -15° to -18° in dry ether, moisture being carefully excluded; the stannochloride of the triazen crystallises from the mixture, and can be kept without decomposition for some hours in a freezing mixture.

p-Tolylazoisimide is an oil of characteristic anis-like odour, b. p. $80^\circ/10$ mm. *o*-Bromophenylazoisimide is obtained pure on distillation in steam; *o*-bromophenyltriazene is extremely unstable; *m*-bromophenylazoisimide has b. p. $99^\circ/100$ mm.; *m*-bromophenyltriazene is extremely unstable, and explodes on gentle heating.

p-Bromophenyltriazene is more stable; the cuprous compound,

forms yellow crystals, and explodes in the flame. The free triazen separates in long, colourless platelets when freshly prepared, m. p. 36.5° , decomposing into nitrogen and bromoaniline; older samples undergo a change manifested by a visible movement in the crystals, and have m. p. 39° . Solution in ether and precipitation with light petroleum gives the more fusible modification. Generally, *p*-bromophenyltriazene is more stable than phenyltriazene; when brought together with benzaldehyde in ethereal solution at -15° , it decomposes.

2 : 4 : 6-Tribromophenyltriazene could not be obtained from tribromophenylazoisimide.

Similarly, *p*-methoxyphenylazoisimide, which forms crystals, m. p. 36° , does not give a triazen on reduction.

Ethyl *p*-azoisimidebenzoate is volatile in steam, and has b. p. $150^\circ/10$ mm., m. p. 18° . Ethyl *p*-triazenebenzoic acid, $C_6H_4(CO_2Et)_2N_3H$, forms a relatively stable stannochloride. The cuprous salt forms lustrous, golden platelets, decomp. 130° , and can be kept for some months. The free triazen crystallises in lustrous granules or feathery needles, m. p. 68° (decomp.). It combines with phenyl cyanate to an azocarbamide.

$\text{CO}\cdot\text{Et}\cdot\text{C}_6\text{H}_4\cdot\text{N}\cdot\text{N}\cdot\text{NH}\cdot\text{CO}\cdot\text{NHPh}$, which crystallises in colourless, lustrous, thin, six-sided plates, m. p. 135° (decomp.). It dissolves in dilute sodium hydroxide with an intense yellow coloration, forming on the addition of acetic acid the *carboxylic acid*,

crystallising in colourless needles, m. p. 172° .

With formaldehyde, the triazen condenses to form a *compound*,

decomp. at 48° to ethyl methylenedi-*p*-aminobenzoate, m. p. 188° .

p-Benzoylphenylazoisimide crystallises in pale yellow, lustrous plates, m. p. 74.5° . The corresponding triazen is relatively stable; it dissolves in ether without the formation of gas, and can be kept in a desiccator for a day.

α - and β -Naphthylazoisimides did not yield triazens on reduction.

E. F. A.

Ionisation, Hydration, and Optical Rotation of White of Egg. WOLFGANG PAULI (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 241—243).—The author gives a brief summary of observations which indicate that egg-albumin behaves as a weak amphoteric electrolyte. The properties of acid and alkaline solutions seem to show that the positive and negative albumin ions are combined with a very large number of molecules of water. The hydration which accompanies ionisation gives rise to considerable differences in the optical rotatory power and the viscosity of egg-albumin solutions. The readiness with which albumin ions are formed by different acids is not simply determined by the relative strengths of the acids, although this appears to be the case for the formation of negative ions on addition of different mono-acid bases.

The phenomenon of ionic hydration, which is so strongly developed in the case of albumin, is supposed to be analogous to that of gelatinisation.

II. M. D.

General Protein Chemistry. II. Precipitation of Globulins at the Isoelectric Point. PETER ROSA and LEONOR MICHAELIS (*Biochem. Zeitsch.*, 1910, 28, 193—199. Compare this vol., i, 646).—It was shown in a previous paper that the sedimentation rate of denatured albumin attains a maximum when the hydrogen ion concentration is that of the isoelectric point, and the same is now shown to be the case for solutions of ordinary (not denatured) serum-globulin, odestin, gliadin, and casein. On this behaviour is based a clear distinction between globulins and albumins; the former are "denaturable" proteins, which, in the ordinary form, precipitate from solution at the isoelectric point, whereas the albumins in the ordinary form are not precipitated by acids, but when denatured also have their sedimentation optimum at the isoelectric point.

The isoelectric constants and relative acidity constants at 18° are as follows: Serum globulin, 0.36×10^{-5} , 2.2×10^3 ; casein from cow's milk, 1.8×10^{-5} , 5.4×10^4 ; gliadin, 6.0×10^{-10} , 6.0×10^5 ; odestin, 1.3×10^{-7} , 2.8, as compared with albumin 0.31×10^{-3} , 1.6×10^3 . Serum-globulin from different animals gave the same values. G. S.

Composition of Nucleic Acid from Yeast. KATHARINA KOWALEVSKY (*Zeitsch. physiol. Chem.*, 1910, 69, 240—264. Compare Levene, Abstr., 1909, i, 54).—Nucleic acid has been prepared from yeast by Altmann's (*Arch. physiol.*, 1899, 526) and by Neumann's method (Abstr., 1899, i, 467; 1900, i, 319), but the product obtained by the latter method is shown to be very impure. The analysis of four specimens prepared according to Altmann gave as a mean $N = 12.52\%$ and $P = 10.02\%$. The low nitrogen value indicates that nitrogenous bases had been removed by acid during the preparation. A specimen prepared on a commercial scale gave $N = 16.16\%$ and $P = 8.65\%$, and this was used for hydrolysis.

When hydrolysed with nitric acid (10 c.c. of nitric acid, D 1.4, + 10 c.c. of water), the products obtained were guanino, 5.16%; adenine, 7.34%; with sulphuric acid (1:2) the products were guanine, adenine, cytosine, and uracil, but no thymine. The uracil is regarded as a secondary product. The nitrogenous portion of the nucleic acid consists of guanine, adenine, and cytosine. The non-nitrogenous portion contains a pento-*c* and not a hexose. The product, C_5H_8O , isolated by Boos (Abstr., 1909, i, 343) in the form of its phenylhydrazone is benzaldehyde, and was present as an impurity in the original phenylbenzylhydrazine used. On the assumption that a molecule of pentose and one of phosphoric acid is present for each molecule of base, the formula $C_{25}H_{42}O_{22}N_{12}P_3$ ($C_5H_5ON_5 + C_5H_5ON_5 + 3C_5H_8O_5 + 3H_3PO_4 = C_{25}H_{42}O_{22}N_{12}P_3 + 6H_2O$) can be deduced. The amounts of bases and pentose actually isolated are less than those required by such a formula, with the exception of guanine. J. J. S.

Guanylic Acid. IVAR BANG (*Zeitsch. physiol. Chem.*, 1910, 69, 167—168).—Polemical. The author defends his formula for guanylic acid, $C_{44}H_{60}O_{34}N_{20}P_3$, against that proposed by Stendel and Brigl, $C_{40}H_{54}O_{30}N_{18}P_3$. W. D. H.

Protamines. ALBRECHT KOSSEL (*Zeitsch. physiol. Chem.*, 1910, 69, 138—142).—*Crenilabrine* is a new protamine separated from the testes of *Crenilabrus pavo*. It yields arginine nitrogen, 42.3%; lysine nitrogen, 11%, and monoamino-nitrogen, 25.1%. Ammonia, tryptophan, and histidine are absent from its cleavage products. It gives Millon's reaction, so tyrosine is probably present. It is therefore not so simple as salmine.

Malenik has prepared sturine from the Caspian sturgeon; the material appears to have suffered in transport, and Malenik has somewhat modified the author's method; he, moreover, found adenine among the cleavage products, which was not the case with sturine made from German sturgeons. W. D. H.

Lipoids. XIV. Leucopoliin. SIGMUND FRÄNKEL and HERBERT ELIAS (*Biochem. Zeitsch.*, 1910, 28, 320—329).—From the acetone extract of human brain, a new phosphatide named *leucopoliin*, was separated. It is crystalline, and of constant composition, the formula of its cadmium compound being $C_{371}H_{720}O_{74}N_{10}P_2Cl_4Cd$. It is a dec-amino-diphosphatide, or a penta-amino-monophosphatide. It contains no

a ethyl group, and yields no base of the choline group. It contains a carbohydrate acid nucleus. It occurs in about equal quantities in white and grey matter, hence its name.

W. D. H.

Invertase. HANS VON EULER, E. LINDBERG, and K. MELANDER (*Zeitsch. physiol. Chem.*, 1910, 69, 152—166).—A certain quantity of yeast always yields the same amount of invertase whether the dried material is extracted with water, or autolysis is allowed to occur. The preparation of invertase obtained in autolysis contained N 0.36%, C 42.3%, and ash 2.07%. It is the most active preparation so far obtained. If 0.05 gram is dissolved in 5 c.c. of 0.5*N*-sodium dihydrogen phosphate, and 20 c.c. of 20% sucrose solution are added, rotation 0° is reached at room temperature (20°) in fourteen minutes.

W. D. H.

Enzymes of Diastase. L. M. LJALIN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 624—633).—The enzymes in various kinds of malt were obtained by precipitation with ammonium sulphate, and the activity of the various preparations in the breaking down of starch was determined as follows: 10 c.c. of a 10% emulsion of starch were placed in a test-tube, the latter immersed in boiling water for half a minute and shaken. After cooling to 20°, a given quantity (0.1, 0.2 . . . c.c.) of the diastase preparation was added, the tube well shaken, and left for half an hour at 20°; 1/2 c.c. of magenta is now added, and the tube inverted. The starch in the tubes in which the magenta is spread evenly through the solution has been completely broken up. The diastase precipitated with ammonium sulphate is always more active than that precipitated with alcohol, and the diastase from air-dried malt, green malt, and the light-coloured malts employed in the manufacture of light beer are the most active, whilst that from dark malt dried at a high temperature is least active.

The fermenting, coagulating, and proteolytic enzymes as well as the oxydases in the diastase obtained from these and other substances are all of the same order of activity according to the source from which they are prepared.

Z. K.

The Deviation of Ferment Action from the Unimolecular Law, with Especial Reference to the Esterases. GEORGE PIERCE (*J. Amer. Chem. Soc.*, 1910, 32, 1517—1532).—The rate of hydrolysis of ethyl butyrate under the influence of lipase has been measured at 37° for different concentrations of the ester and the enzyme. In some experiments the progress of the reaction was found to be in satisfactory agreement with the equation for a unimolecular change, but this is not generally the case, and the actual course in a particular experiment appears to be determined by the relative concentrations of ester and enzyme. Another factor which is of importance is the acid produced by the hydrolysis, for this apparently diminishes the activity of the enzyme.

In solutions which contain the same amount of ester and acid, the time required for the hydrolysis of a given quantity of ethyl butyrate is inversely proportional to the concentration of the enzyme. For

given enzyme and acid concentrations, the time required for the decomposition of the same amount of ester is independent of the ester concentration, provided that this exceeds a certain limiting value. It thus appears that the activity of the enzyme is independent of the ester concentrations where this is varied between considerable limits.

To account for the observations, it is supposed that the enzyme combines with the ester to form an intermediate compound, the amount of which is proportional to the concentrations of the free enzyme and the ester. This compound then undergoes hydrolysis in accordance with the mass action law.

It is shown that the observed facts are consistent with this hypothesis, and that the action is similar to that which probably takes place in the inversion of sucrose under the influence of invertase.

H. M. D.

Benzophosphide. PERCY N. EVANS and JENNIE TILT (*Amer. Chem. J.*, 1910, 44, 361—365).—EVANS and Vanderkleed (*Abstr.*, 1902, i, 273) have described dichloroacetyl phosphide,

$$\text{CHCl}_2\cdot\text{CO}\cdot\text{PH}_2$$

and an account is now given of the preparation and properties of benzoyl phosphide, $\text{C}_6\text{H}_5\cdot\text{CO}\cdot\text{PH}_2$. In view of the analogy of these compounds to the amides, it is suggested that they would preferably be termed "dichloroacetophosphide" and "benzophosphide."

Benzophosphide, prepared by treating benzoyl chloride for six weeks with a current of dry phosphine, generated by the action of phosphorus on alcoholic potassium hydroxide, forms a slightly yellow, or sometimes white, powder. It does not give a definite m. p., but begins to decompose at about 125°. When heated in a current of dry nitrogen, it gradually decomposes above 75° with evolution of phosphine. It is slowly attacked by water or moist air.
 E. G.

Action of Arsenic Acid on Gallic Acid. LEO F. ILJIN (*J. pr. Chem.*, 1910, [ii], 82, 451—462).—Walden, (*Abstr.*, 1899, i, 212) supports Schiff's statement that digallic acid is one of the products of the reaction between gallic and arsenic acids in 95% alcoholic solution. The author has repeated Walden's experiment, but cannot obtain digallic acid, the product free from arsenic being separable by ethyl acetate and petroleum into two fractions, neither of which exhibits the properties of digallic acid; one fraction consists of gallic acid, the other (the smaller) of ethyl gallate.

With regard to the organic arsenic compounds formed in the preceding reaction, the author's results differ from those of Biginelli (*Abstr.*, 1909, i, 801). The arsenical substance obtained by the author in the preceding experiment can be separated, in aqueous ethereal solution, into two fractions by the addition of sodium chloride, one of which does, and the other does not, yield a precipitate with a solution of gelatin. The former is still under investigation; the latter is obtained, after purification, in long needles of the composition $(\text{C}_9\text{H}_9\text{O}_2)_3\text{AsO}$.
 C. S.

General and Physical Chemistry.

Solutions. I. Relations between Density and Refractive Index in Binary Mixtures. F. SCHWERS (*Bull. Soc. chim.*, 1910, [iv], 7, 875-882).—Pulfrich's formula, $(D - D_v)/D = a(N - N_v)/N$, expressing the relationship between change of volume and change in refractive index from the calculated values for any binary mixture of liquids, does not admit of an absolute comparison between the two changes, since in devising the formula Pulfrich introduced the density value in arriving at the refractive index contraction, N_v . The author suggests instead the relation: $C_n = AC_v$, where $C_n = 100(n - n_v)/n$, n being the observed refractive index of the mixture and n_v the calculated value, and $C_v = 100(D - D_v)/D$, D being the observed specific gravity and D_v the calculated value. The value of A has been determined for mixtures of water with alcohol, acids, aldehydes, ketones, glycols, hydroxy-acids, esters, ethers, amines, cyclic compounds, etc., and from the results obtained the following conclusions are drawn. The value of A for a mixture of two given liquids is independent of (1) the concentration of either constituent, (2) the wave-length of the light used, and (3) to a certain extent of the temperature of observation. It is specific for each mixture, and its magnitude is dependent on the molecular volume and structure of each constituent.

These observations lend no support to the "hydrate" theory of solution, since if "hydrates" were formed it is inconceivable that A would be independent of the concentration of each constituent in a given binary mixture.

When a substance undergoes change in volume (by compression, polymerisation, or fusion), the change in refractive index exhibits a relation to the change in volume, which is peculiar to each substance and depends on its constitution.

T. A. H.

Fluorescence and Band Spectra of Oxygen. WALTER STEUBING (*Ann. Physik*, 1910, [iv], 33, 553-584).—It has been found that oxygen exhibits three banded emission spectra, one of which lies in the region extending from the red to the greenish-yellow rays, whilst the others are in the ultra-violet. Detailed observations relating to the three spectra are recorded. The first ultra-violet spectrum, which has usually been attributed to water-vapour by previous observers, is shown to be characteristic of oxygen. The bands of this spectrum, in the neighbourhood of $185\mu\mu$, were repeatedly obtained under conditions which seemed to ensure the absence of water vapour. These conditions were such that the strongest hydrogen lines are not visible, and the author concludes that the first ultra-violet spectrum exhibited by tubes containing oxygen cannot be due to water vapour.

The experimental data are discussed from the point of view of Stark's electron theory.

H. M. D.

Dispersion of Light by Potassium Vapour. P. V. BEVAS (*Proc. Roy. Soc.*, 1910, 84, A, 209—225).—In continuation of previous experiments (compare Abstr., 1909, ii, 783; this vol., ii, 87) on the dispersion produced by potassium vapour, quantitative measurements have now been made for different wave-lengths. The observed deviations extend over the whole of the visible spectrum and for a considerable distance in the ultra-violet. Strong absorption takes place at the lines of the principal series, and anomalous dispersion is found in the neighbourhood of these lines. This phenomenon has been investigated for seven of the pairs forming the principal series lines. As the pairs in this series get closer together with diminishing wave-length, the dispersion effects can only be seen outside the lines forming a pair, and a lack of symmetry in the dispersion curves is found which corresponds with the different intensities of the lines forming the pair. The quantitative data are discussed in reference to Sellmeier's theory.

In regard to the natural periods which correspond with the series lines, it is suggested that these are not due to the atom itself, but to differentiated forms of the atom exhibiting real differences in physical properties.

H. M. D.

Series Spectrum of Mercury. S. R. MILNER (*Phil. Mag.*, 1910, [vi], 20, 636—642).—It has been found that the photographic records of the spectrum of the mercury are in a vacuum show no trace of the continuous back-ground even when the time of exposure is more than fifty times as long as the normal exposure suitable for registration in the case of the mercury are in air. These records show a large number of lines which have not been observed previously.

The wave-lengths of the lines of the principal series down to $m=16$ in Rydberg's formula, and of the diffuse and sharp series down to $m=16$ and $m=14$ respectively, have been measured. The data are utilised to show the accuracy of Rydberg's empirical law, according to which the difference of the frequency of the convergence limit of the principal series and that of the common limit of the sharp and diffuse series is equal to the frequency of the first line of the sharp series.

The agreement is such as to indicate the absolute accuracy of this law.

H. M. D.

Influence of Pressure on the Absorption of Ultra-red Radiation by Gases. EVA VON BAHR (*Ann. Physik*, 1910, [iv], 33, 585—597).—In continuation of previous measurements (Abstr., 1909, ii, 630) of the dependence of the ultra-red absorption on the pressure, experiments have been made with sulphur dioxide, hydrogen chloride, nitrogen peroxide, ozone, benzene, and methyl alcohol. As in the case of the gases examined previously, the absorption of the first four substances increases as the total pressure on the gas is raised, and tends towards a constant maximum value. For benzene and methyl alcohol, on the other hand, the absorption is independent of the pressure between 5 and 760 mm. The collected data indicate that, in general, the pressure at which maximum absorption is reached diminishes as the size of the molecules of the gas increases.

Experiments with nitrous oxide show that a change of pressure, not only influences the quantity of the absorbed radiation, but also brings about a change in the character of the absorbed rays. This variation in the nature of the absorbed radiation is inconsiderable, except at lower pressures.

H. M. D.

A New Radiant Emission from the Spark. ROBERT W. WOOD (*Phil. Mag.*, 1910, [vi], 20, 707—712).—When a condenser spark passes between aluminium electrodes screened by a metal strip, although nothing is visible to the eye, a photograph, taken with a quartz lens shows that the air round the spark is glowing with ultraviolet light for a very short distance. This was shown not to be due to fluorescence of the air caused by the absorption of Schumann waves, or to scattering of the light of the spark by air or dust. The light given out by the emission is embraced between the wave-lengths of 300 to 310, and its spectrum consists of two broad bands, one very strong, the other weaker, identical with the "water bands" of the oxyhydrogen flame. In addition are three lines at 3576, 3537, and 3569, identical with those attributed by Eder and Valenta to nitrogen in the spectrogram of the spark between wet carbon poles. No difference was observed whether the spark took place in dry or moist air, but in oxygen there was practically no emission, whilst in nitrogen it was much brighter and extended a greater distance. No substance has been found transparent to the emission itself. A jet of oxygen killed the emission, but in a jet of nitrogen the emission shot out much further and was of greater intensity. The emission appears to be shot out with very high velocity, for it is not affected by air currents. The new emission appears of great importance in connexion with the origin of the so-called "water-bands," and it is possible it may be identical with the "Entladungsstrahlen."

F. S.

Rotatory Power of Tartaric and Malic Acids in Presence of Ammonium Molybdate and Sodium Phosphate. G. MADERNA (*Atti R. Acad. Lincei*, 1910, [v], 19, ii, 130—138).—Seeking an explanation of the phenomena observed in connexion with the precipitation of ammonium phosphomolybdate in the presence of organic acids (this vol., ii, 804), the author has repeated and extended the work of Gernez (*Abstr.*, 1889, 859, 1147), more especially in order to obtain indications as to whether the phosphate radicle enters into the organic complex. He confirms the results of Gernez as regards the rotatory power of tartaric acid in the presence of ammonium molybdate. Rise of temperature affects the rotatory power differently at different concentrations. The concentrations at which a decrease is observed are those at which a precipitation of phosphomolybdate can be effected. Sodium phosphate does not affect the rotatory power of tartaric acid to any marked extent, its influence being in fact no greater than that of sodium or ammonium chlorides. The action of sodium phosphate and ammonium molybdate together is similar to that of the latter substance alone, so that it is probable that the complex substances in solution involve only the acid and the molybdate. The results obtained with malic acid were similar. The author finds reason to doubt the state-

ments of previous workers as to the composition of the complex compounds present in these solutions.

R. V. S.

Action of Quinones and their Sulphonic Derivatives on Photographic Images from Silver Salts. AUGUSTE LUMIÈRE, LOUIS LUMIÈRE and ALPHONSE SEYEWETZ (*Compt. rend.*, 1910, 151, 616—618).—*p*-Benzoquinone and its sulphonic derivative act as "reducing" agents in acid solution towards the negative photographic image. A solution containing 2% of *p*-benzoquinone and 0.5% of sulphuric acid is recommended for use in photography. This bleaches the opaque portions of the image more rapidly than the half tones. The reaction is explained by the equation:

In the presence of an alkali chloride or bromide, however, *p*-benzoquinone produces strong intensification. The effect is less marked in the case of the sulphonic derivative. The solution recommended contains 0.5% of *p*-benzoquinone and 2.5% of potassium bromide. The reaction is represented as: $2\text{C}_6\text{H}_4\text{O}_2 + 2\text{KBr} + 2\text{Ag} + \text{H}_2\text{O} = \text{C}_6\text{H}_4(\text{OK})_2 + \text{C}_6\text{H}_4(\text{OH})_2 + \text{Ag}_2\text{OBr}_2$.

W. O. W.

Temperature-coefficient of the Bleaching of Colouring Matters in the Visible Spectrum. B. SCHWEZOFF (*Zeitsch. Photochem.*, 1910, 9, 65—70).—The influence of temperature on the rate of bleaching of cyanine, pinachrom, pinaverdol, and pinacyanol when exposed to light of known wave-length has been investigated. For a rise of 10° the increase in the rate of bleaching was found to vary from 1.036 to 1.084. These temperature-coefficients are the smallest which have yet been observed in connexion with photochemical changes.

H. M. D.

Acceleration of the Bleaching of Colouring Matters by Aromatic Compounds. GOTTFRIED KÜMMEL (*Zeitsch. Photochem.*, 1910, 9, 54—60).—The increased sensitiveness of colouring matters towards light in presence of certain aromatic compounds has been measured by means of Vogel's actinometer, using specially prepared chromate paper as a comparison standard. Observations were made on cyanine, methylene-blue, and erythrosin, the substances added being anethole, eugenol, *isoeugenol*, safrole, *isosafole*, propenylphenol, and vinylanisole. To obtain comparable results, these were added in such quantity that the molar concentration of the sensitiser in the exposed collodion or gelatin film was in all cases twenty-five times as large as that of the colouring matter. From the tabulated results it is found that safrole and *isosafole* lower the light sensitiveness of all three colouring matters. The other five substances accelerate in general the rate of bleaching, and the sensitising influence of the members of the group increases as the molecular weight decreases.

Experiments are described in support of the view that the bleaching is due to an oxidation process, and that the active substances accelerate the bleaching by acting as oxygen carriers.

H. M. D.

The Probability Variations in the Distribution of α -Particles. ERNEST RUTHERFORD and HANS GEIGER [with a note by H. BATEMAN] (*Phil. Mag.*, 1910, [vi], 20, 698—707).—The object of the experiments was to see whether the rate of emission of α -particles was governed by the laws of probability, or whether the expulsion of one α -particle might not precipitate the disintegration of a neighbouring atom. The scintillations from the α -particles of a polonium source were observed by eye, and recorded on a chronograph tape by closing an electric circuit by hand at the instant of each scintillation. Two thousand scintillations a day were counted for five days, and the chronograph records examined. The differences between the number of scintillations observed, in successive one-eighth, one-quarter, and one minute intervals respectively, and the true average number (total number divided by total number of intervals) were compared with the expression deduced by Bateman from the theory of probability. If x be the true average number of particles observed in any interval, the probability that n α -particles are observed in the same interval is $\frac{x^n}{n!} e^{-x}$. The agreement between theory and experiment was found to be practically perfect, especially for the one-eighth minute intervals, and there is no evidence of greater variations than would be expected from a random distribution. F. S.

Rate of Emission of α -Particles from Uranium and its Products. J. N. BROWN (*Proc. Roy. Soc.*, 1910, A, 84, 151—154).—The number of α -particles emitted from pitchblende films of known weight per unit area has been determined by the scintillations produced in zinc sulphide. For thin enough films the number was proportional to the thickness, so that the total number emitted per gram per second could be calculated. The percentage of uranium in the pitchblende was determined. Per gram of uranium in the pitchblende the number emitted per second was 7.36×10^4 , in fair agreement with the number, 9.25×10^4 , calculated from Rutherford's value for radium. F. S.

The Number of α -Particles Emitted by Uranium and Thorium and by Uranium Minerals. HANS GEIGER and ERNEST RUTHERFORD (*Phil. Mag.*, 1910, [vi], 20, 691—698).—The number of α -particles emitted per second from one gram of uranium, calculated from the number emitted by radium and the ratio between uranium and radium in minerals, is 11,600, if each uranium atom emits one α -particle. On Boltwood's view (*Abstr.*, 1908, ii, 454) that two α -particles per atom are emitted by uranium, and one from each of the subsequent α -ray products, the calculated number of α -particles emitted per second from an old mineral containing 1 gram of uranium is 96,700. The number has been experimentally determined by counting the scintillations produced on a zinc sulphide screen from very thin films of material. The scintillations from uranium are much fainter and more difficult to count than from the uranium minerals and from thorium. Films of pure uranoso-uranic oxide, selected Joachimsthal uraninite, and thorium oxide, five weeks old, from thorite, prepared by Boltwood, were employed. The number of α -particles per second per

gram of uranium or thorium were for these three preparations 23,700, 96,000, and 27,000 respectively. These represent the mean values, corrected for defects of the screen, escape of emanation from the uraninite, and decay of radio-thorium in the thorium oxide. These experiments confirm the view that uranium alone gives two α -particles, all its products giving only one per atom disintegrating. The agreement between the calculated and experimental numbers is closer than could be expected. It was observed that the scintillations from ionium were as bright as, if not brighter than, those from uranium, showing that the range of the α -particle from the latter is not greater than that of ionium (2.8 cm. of air), which is the lowest hitherto measured. A preliminary measurement of the range of the uranium α -particle gave 2.7 cm.

F. S.

The Scattering of Homogeneous β -Rays and the Number of Electrons in an Atom. J. ARNOLD CROWTHER (*Proc. Roy. Soc.*, 1910, A, 84, 226—247).—The fact that β -rays are scattered in a thickness of material far too small to effect the velocity of the rays renders experiments on scattering more simple theoretically than those on absorption. The results are interpreted of the theory of J. J. Thomson (*Camb. Phil. Soc. Proc.*, 1910, 15, v), which is borne out in all points. Homogeneous β rays from a radium source, produced in the manner previously described (compare this vol., ii, 672), are scattered by screens of various materials and thickness, and, by means of stops of various sizes, the scattered rays are confined to a known angle, and pass into an ionisation chamber so shaped that the paths of all rays through it are similar. The following results deduced from the theory were experimentally established: (1) for rays of given velocity and cone of given angle the intensity of the radiation, I , varies with the thickness, t , of material traversed according to the formula: $I/I_0 = 1 - e^{-kt}$, where k is a constant; (2) $\phi/\sqrt{t_m} = \text{constant}$, where t_m is the thickness necessary to cut down to one-half the radiation through a stop of angle ϕ ; (3) $mv^2/\sqrt{t_m} = \text{constant}$, where mv^2 , twice the kinetic energy of the rays, is obtained from the magnetic deflexion. In addition, the results lend themselves to a calculation of the number of electrons in an atom, which is found to be three times the atomic weight for all atoms examined on the assumption that the positive electricity within the atom is not in an electronic condition, but uniformly distributed. An important experiment showed that homogeneous β -rays, when passed through only 0.001 cm. of platinum, are completely scattered, and are then absorbed by aluminium exponentially, whereas the absorption in aluminium alone is quite different, the curve having two inflexions in opposite directions, making the middle part nearly linear, as Wilson found. The view is taken that completely scattered homogeneous β -radiation is exponentially absorbed.

F. S.

Influence of the Temperature on the Change of Radioactive Substances. II. HEINRICH W. SCHMIDT and PAUL CERMAK (*Physikal. Zeitsch.*, 1910, 11, 793—800. Compare Abstr., 1909, ii, 9).—The changes in β -rays from a quartz tube containing radium during

and after heating in a platinum-foil furnace at 1200° to 1300° have been exhaustively examined, and, amid much irregular variation, certain generalities have transpired. The γ -rays throughout in all the experiments show absolutely no definite change in intensity, while the β -rays, on heating the tube, suddenly increase to a maximum, remain constant during the heating (usually one-half to one hour), then, on cooling, very rapidly and steadily decrease to the value before heating, then increase in three hours to the value during heating, and finally, after many days, return to the value before heating. These results are attributed to (1) the gasification of the products radium-*A*, *B*, and *C* by the heating, whereby the absorption of β -rays, which takes place in the radium itself when these products are formed within it, no longer occurs; (2) the sudden adsorption into the mass of the radium again of these products on cooling; (3) the formation in three hours of a new set of products on the walls of the tube and not within the radium, due to the complete expulsion of emanation from the radium during heating; (4) the decay of this emanation with the four-day half-period, and the re-growth of fresh emanation and products within the radium as initially. All the quartz tubes after repeated heatings became porous, and allowed emanation to escape, but some tubes lasted far better than others. The β -rays of uranium-*X* were also examined similarly to those of radium, but apart from initial changes, due to the heat altering the distribution of the substance, no definite changes occurred. The conclusion is arrived at that none of the experiments prove any direct influence of temperature on the rate of transformation of a radioactive substance.

F. S.

The Consequences of the Corpuscular Hypothesis of the γ - and *X*-Rays, and the Range of β -Rays. WILLIAM H. BRAGG (*Phil. Mag.*, 1910, [vi], 20, 385—417).—The paper reviews exhaustively the present state of knowledge of the ionisation, penetration, reflexion, scattering, transformation, etc., of cathode-, *X*-, α -, β -, and γ -rays from the point of view of the "corpuscular" or "entity" hypothesis, which recognises that each type of radiation consists of individual entities, to be followed, each by itself, from its origin through all its changes of direction and sometimes changes of form (conversion of cathode- into *X*-rays, of γ - into β -rays) until its gradually diminishing energy becomes too small to be detected. A method is described of determining the average range of β -rays in various substances, defined as the average weight of substance crossed by the β -ray, when its zig-zag path is straightened out, before it disappears. It is deduced theoretically that the relative ionisations inside similar vessels of different materials, thick enough in the walls to prevent β -rays penetrating them, exposed to a constant stream of γ -rays, gives the relative average ranges of the β -rays in the metals. Results so obtained by H. I. Porter show the greatest range in lead and the least in card. The greater apparent absorption in lead than in other substances is due to the more zig-zag character of the path of the β -ray in lead, the total length of path (in weight units) being actually the greatest in lead. The view is strongly upheld that γ - and *X*-rays do not ionise gases directly at all, but only through first being transformed into

β - or cathode-radiation. The chief evidence against the corpuscular theory is from the work of Barkla on polarisation of X -rays, which, however, is considered a much more simple phenomenon than the polarisation of light, and one not necessarily calling for a wave-motion explanation. The attempt is made to explain the homogeneous secondary X -radiation of Barkla by a double transformation, first of primary X -rays into cathode-rays, and, secondly, the reconversion of the latter into "secondary" X -rays, the existence of a critical speed being assumed, which it is necessary for a cathode-ray falling on an atom to possess in order to produce an X -ray.

F. S.

Typical Cases of Ionisation by X -Rays. CHARLES G. BARKLA (*Phil. Mag.*, 1910, [vi], 20, 370—379).—The relative ionisations in air, carbon dioxide, and ethyl bromide produced by the homogeneous secondary X -rays from twelve elements with atomic weights lying between iron and antimony have been studied. The iron radiation was seventy times more easily absorbed than that from antimony, and throughout the whole range of penetrating power the ionisation in carbon dioxide was proportional to that in air, being about $1\frac{1}{2}$ times greater.

Similar results hold for other gases less dense than carbon dioxide. For ethyl bromide and air the proportionality held for radiations not more penetrating than the bromine radiation. For more penetrating secondary X -rays the relative ionisation of ethyl bromide rises suddenly to over three times its previous value, and then more slowly with increasing penetrating power to between five and six times. These results are similar to those previously found for the absorption of the radiations. Similar variations occur in the ionisations in vapours of methyl iodide, stannous chloride, and selenium chloride at the particular penetrating power characteristic of iodine, tin, and selenium, while carbon, hydrogen, and chlorine give no characteristic secondary X -radiation. No anomalous cases of X -ray ionisation have been observed. The penetrating power of the characteristic secondary X -radiation emitted by the constituent elements of the gas determine the way in which the ionisation depends on the penetrating power of the ionising radiation.

F. S.

The Accumulation of Helium in Geological Time. IV. ROBERT J. STRUTT (*Proc. Roy. Soc.*, 1910, A, 84, 194—196. Compare this vol. ii, 175).—Several examples of Archean rocks show a higher ratio of helium to radioactive matter than thorianite. The minimum age indicated by the helium ratio for sphenes from Archean rocks is about 700 million years. A sphen from the recent volcanic rocks of the Zaacher Sea showed a helium ratio at least two thousand times less. An explanation for the anomalous case of beryl which contains helium out of all proportion to its radioactive content, due to Boltwood, is that in the crystallisation of the beryl one of the longer-lived products of disintegration, as radium, ionium, etc., has separated also, of which after a few thousands of years nothing would be recognisable but the helium to which it had given rise.

F. S.

The Absorption of Radium Emanation by Coconut Charcoal. JOHN SATTERLEY (*Phil. Mag.*, 1910, [vi], 20, 778—788).—The first point tested was whether the same fraction of radium emanation, whatever the amount may be, is absorbed by charcoal when the experimental conditions are the same. For solutions of strengths 3×10^{-9} and 6×10^{-9} gram of radium, but not for stronger solutions, proportionality between the emanation retained and the amount of radium present held good, justifying the method previously employed (*Abstr.*, 1908, ii, 918). With a steady source of emanation the fraction absorbed decreases with the length of the experiment, as though the charcoal became saturated. The humidity of the air stream made no difference. A constant air stream was sent through two charcoal tubes in series. The ratio of the amount of emanation absorbed in the second to that in the first rose with the time of experiment. With tubes 8 sq. cm. in cross section containing 30 cm. length of coarsely powdered coconut charcoal, and an air stream 0.5 litre per minute continued twenty-one hours, 62 per cent. of the total emanation is absorbed. For air streams 0.11, 0.25, and 0.80 litre per minute, the fractions absorbed were respectively 0.86, 0.73, and 0.23. F. S.

The Relation between Uranium and Radium. V. FREDERICK SODDY (*Phil. Mag.*, 1910, [vi], 20, 340—342).—The rate of growth of radium in the three uranium solutions, which previously had proceeded according to the square of the time (compare this vol., ii, 10), has since not been maintained, and it has been found that the constant of the electroscope employed has changed, the instrument now being about 10% more sensitive than at first. Previous estimates of the period of the parent of radium (ionium) are therefore in error, the data still only affording the means of calculating the minimum period of the long-lived intermediate substance, assuming there is but one, and not as proving the production of radium from the uranium. The minimum period from present results is 35,000 years, and the true period may be much greater. A method of obtaining an upper limit for the period from a study of the intensely active ionium preparations separated from thirty tons of pitchblende by the Austrian Government is given. F. S.

The Rays and Products of Uranium-X. II. FREDERICK SODDY (*Phil. Mag.*, 1910, [vi], 20, 342—345).—The preparations of uranium-X previously described (this vol., ii, 10) have now been under observation for periods of a year to eighteen months, and in none has there been any increase of the initial α -radiation present, which is ascribed to an impurity present from the start in the uranium. This is in agreement with the revised estimate for the minimum period of ionium (compare preceding abstract), for if this is greater than 35,000 years the detection of the ionium produced from the uranium-X by means of its α -rays would not be possible with the arrangements employed. The proportion of β -rays in the radiation of uranium possessing an apparent value for H_p above 8640 is given as $1/750$ th. Tests to see whether actinium is produced from the uranium-X pre-

parations have so far given negative results. Actinium is present in all the preparations, but it is ascribed to initial impurities in the uranium.

F. S.

The Ratio between Uranium and Radium in Minerals
 FREDERICK SONNY and RUTH PIRRET (*Phil. Mag.*, 1910, [vi], 20, 345—349).—Determinations are given of the ratio of radium to uranium in autunite and thorianite (compare Mlle. Gleditsch, *Abstr.*, 1909, ii, 714). The ratio for thorianite was found to be only 3% higher than for Joachimsthal pitchblende, while for autunite (of Portuguese origin) it was very low, being only 44.5% of that of pitchblende. The natural explanation is that autunite is of such recent formation that the uranium-radium series is not yet in equilibrium. The specific α -activities of the oxides of uranium separated from autunite, pitchblende, and thorianite were practically the same, which excludes the possible explanation that the variations in the uranium-radium ratio are due to two successive slow α -changes in uranium itself.

F. S.

Selective Photo-electric Effect of Potassium Mercury Alloys.
 ROBERT POHL and P. FRINGSHEIM (*Ber. Deut. physikal. Ges.*, 1910, 12, 697—710. Compare this vol., ii, 379—472).—The photo-electric sensitiveness of potassium amalgams of varying composition has been investigated. Amalgams containing 2.5 to 17.3 atoms % of potassium do not exhibit the selective effect at $\lambda = 436 \mu\mu$ which is characteristic of potassium. This selective action is, indeed, no longer found in the case of either liquid or solid alloys containing as little as 21 atoms % of mercury.

For alloys containing from 17 to 70 atoms % of potassium a selective effect has been found in the neighbourhood of $\lambda = 386 \mu\mu$, and for alloys which contain from 5 to 10 atoms % of potassium it is probable that there is a further characteristic photo-electric effect at about $\lambda = 313 \mu\mu$. The selective effect at $\lambda = 386 \mu\mu$ is supposed to be due, at any rate in the case of the solid alloy, to the compound K₂Hg.

H. M. D.

The Ionisation Produced by the Splashing of Mercury.
 J. J. LONSDALE (*Phil. Mag.*, 1910, [vi], 20, 464—474).—The ions produced by splashing have been usually examined for volatile liquids, and have been found to move with very small velocity. Hence mercury was tried to see if this was due to condensation of vapour on the ions. The results were found to be independent of electrification of the mercury and of its purity, but depended on the nature of the splash-plate. With iron the positive ions were in great excess. Cleaning the plate did not much affect the positive ionisation, but reduced the negative. Platinum gave smaller positive and negligible negative, mercury negligible positive but larger negative, ionisation. The minimum mobility of the ions with iron splash-plate was 0.013 (cm. per volt-cm.) for the positive and 0.004 for the negative. But in the former case the saturation curve showed a second maximum, due either to ions of

smaller mobility or to neutral doublets broken up by the action of the field. The latter explanation was favoured by further experiments, negative ions in some cases being initially absent, but produced in the gas by the application of a field. The negative ions appear to arise altogether from the breaking up of the doublets. By varying the height of fall of the mercury, it was found that no slow positive ions and no negative (therefore no doublets) are produced when the height is below 21.5 cm. The saturation curves, when heated aluminium phosphate or lime was used as the source of the ionisation, showed similar peculiarities for the positive ions. F. S.

Specific Change of the Ions Emitted by Hot Substances. II.

OWEN W. RICHARDSON and E. R. HULBERT (*Phil. Mag.*, 1910, [vi], 20, 545-559. Compare *Abstr.*, 1908, ii, 1009).—The ratio of the charge to the mass for the positive ions emitted by heated metals has been determined for platinum, palladium, gold, silver, copper, nickel, iron, osmium, tantalum, tungsten, brass, "nichrome," and steel. From this the mass of the ion in terms of the hydrogen atom as unity is deduced, on the assumption that unit charge is carried. A correction reducing the values to 0.62 of the experimental is made, because the value for the negative ion from platinum found by the same apparatus and method was wrong to this extent. The general result is to show that the mass of the positive ion from all substances is of the same order, the mean value being 23.3. Some of the substances proved difficult on account of irregularities in the ionisation, and because the initial value was different from the values after some heating. The suggestion is made that the positive ionisation is due to sodium as a common impurity in all the metals. F. S.

Positive Electrification due to Heating Aluminium Phosphate. A. E. GARRETT (*Phil. Mag.*, 1910, [iv], 20, 573-591).—When aluminium phosphate is heated at about 1200°, large numbers of positive ions are emitted, and this phenomenon has been investigated by measuring the conductivity imparted to the surrounding gaseous atmosphere. The emission effect decays with time, and the activity of the substance at any moment can be represented by an expression of the form: $A(e^{-\lambda_1 t} - e^{-\lambda_2 t}) + B(1 - e^{-\lambda_3 t})$. During the first portion of the period of decay, the nature of the surrounding gas and the traces of water present in the active substance have a marked influence on the form of the decay curve. This is no longer evident when the steady state has been reached.

For a given temperature, the current due to the positive ions has a maximum value for a particular pressure; this pressure diminishes as the temperature is raised. At constant pressure the relationship between the current and the absolute temperature can be expressed satisfactorily by means of Richardson's formula.

Measurements of the value of e/m show that the smallest positive ions, which are emitted at the lowest pressures, are comparable in size with the hydrogen atom. In consequence of the high velocity of the ions at low pressure, even in the absence of an external field, a tube

containing strongly heated aluminium phosphate can be used as a rectifier for alternating currents.

Observations are also recorded which seem to show that neutral doublets as well as ions are emitted by the heated substance.

H. M. D.

The Electrical Conductivity of Liquid Alloys. KARL BORNEMANN and PAUL MÜLLER (*Metallurgie*, 1910, 7, 396-402).—Very few data exist as to the electrical conductivity of liquid alloys. The experiments described have been made in glass or quartz tubes, heated in an oil-bath or an electric furnace, according to the temperature required. Iron, platinum, or carbon electrodes are used, auxiliary electrodes being introduced in quartz tubes at different points for the measurement of the fall of potential.

The liquid alloys of sodium and potassium give a conductivity-concentration curve which exactly resembles that typical of a continuous series of solid solutions, such as gold and silver. The conductivity of each liquid metal is lowered by the addition of the other, and the curve has a well-marked minimum. There is no indication of the compound Na_3K , the existence of which is shown on the freezing-point curve as a change of direction, and it therefore appears that this compound is much dissociated in the molten alloys.

On the other hand, liquid alloys of lead and tin exhibit a conductivity which varies with the concentration in an almost perfectly linear manner. The curves of temperature-coefficients of the conductivity follow a similar course to the conductivity curves.

Sodium amalgams exhibit a depression of conductivity at both ends of the series, rising to an intermediate maximum at a point corresponding with the compound NaHg_2 , which probably exists in the liquid in a largely undissociated condition, as evidenced by the very high freezing point of the compound in comparison with those of its components. A similar, but less marked, maximum is caused in the amalgams of potassium by the compound KHg_2 . A new criterion for the existence of compounds in solution is thus obtained.

Observations on dilute amalgams show that the conductivity of mercury is lowered by the addition of either of the alkali metals, but the older observations, that the conductivity is raised by the addition of other metals, are confirmed. The abnormally low temperature-coefficient of mercury (0.001) was attributed by Liebenow to the presence in the liquid of two or more different kinds of molecules, giving it the properties of an alloy. In accordance with this view, the addition of the alkali metals, which form compounds with mercury, and thus increase the number of complex molecules, lowers its conductivity, whilst the indifferent metals, which dissolve in the monatomic form, raise it. It is shown that lead, which has an even lower temperature-coefficient than mercury, has its conductivity raised by the addition of metals which do not combine with it, such as zinc, cadmium, antimony, and bismuth, although the conductivity of bismuth is less than that of lead. Potassium and sodium have a normal temperature-coefficient (0.004), and their conductivity is

lowered by the addition of other metals, whether they form stable compounds or not.

Heterogeneous mixtures of liquid metals, such as lead and zinc, have a conductivity strictly proportional to the concentration, whether the liquids are emulsified or in distinct layers. The temperature at which the separation of a homogeneous liquid alloy into two layers takes place may be determined more accurately by the conductivity than by the thermal method, being indicated by an abrupt change of direction in the conductivity-temperature curve. C. H. D.

The Electrical Conductivity and Hardness of Alloys of Silver and Copper. NIKOLAI S. KURNAKOFF, NIKOLAI A. PUSMIN, and N. SENKOWSKY (*Zeitsch. anorg. Chem.*, 1910, 68, 123-140; *J. Russ. Phys. Chem. Soc.*, 1910, 42, 733-751).—The electrical conductivity and hardness of the alloys of silver and copper have been re-determined with special precautions. The conductivity falls from that of pure copper until 4 atomic % Ag is reached, after which it remains nearly constant until 91 atomic % Ag is reached, and then rises rapidly to that of pure silver. The curve for hard drawn wires closely resembles that for the annealed metals, but the conductivity is throughout lower. The curves representing the temperature-coefficient of the conductivity have exactly the same form.

The determinations of hardness are best made by means of Drinell's ball test on specimens annealed at 650-700°. The curve obtained is the converse of the conductivity curve, and indicates the same limits of concentration of the solid solutions, namely, 0-4 and 91-100 atomic % Ag. The alloys thus represent the simplest type of a series composed of two solid solutions separated by a gap. C. H. D.

Conduction of Electricity Through Solid Silver Chloride. II. MAX LE BLANC and FRITZ KERSCHBAUM (*Zeitsch. Elektrochem.*, 1910, 16, 680-681).—The conductivity of solid silver chloride produced by prolonged treatment with continuous current (this vol., ii, 382) is shown to be due to excessively thin threads of metallic silver. T. E.

Potential of Iron Calculated from Equilibrium Measurements. ARTHUR B. LAMB (*J. Amer. Chem. Soc.*, 1910, 32, 1214-1220).—Richards and Behr (*Abstr.*, 1907, ii, 222) have found that the true potential of iron is 0.18 volt for the porous form, and 0.15 volt for the massive form, the calomel electrode being taken as -0.56 volt, whilst other authors have obtained values about 0.1 volt lower.

A calculation from existing data has now been made, which shows that the potential of iron against a molecular normal solution of ferrous ions is 0.192 volt, the calomel electrode being taken as -0.564 volt. E. G.

Evolution of Gas and Capacity of the Lead Accumulator. FRANZ STREITZ (*Zeitsch. Elektrochem.*, 1910, 16, 747-754).—The quantities of oxygen and hydrogen evolved during the charge of a

small accumulator are compared with those given off from platinum electrodes through which the same current passes. The differences give the capacities of the plates, and these are compared with the capacity of the accumulator when discharged. About 94% of the charge is obtained from the lead plate and about 87% from the lead peroxide plate. It is also shown that the fully charged plates continue to absorb a little hydrogen or oxygen if the charging current is continued. In the case of the lead plate, this is due to occlusion of hydrogen; in that of the lead peroxide plate, it is due to slow oxidation of the lead framework supporting the peroxide.

T. E.

Chemical Action of the Silent Electrical Discharge. A. MOSER and N. ISGARISCHEFF (*Zeitsch. Elektrochem.*, 1910, 16, 613—629).—Various gases are submitted to the action of the silent discharge in ordinary ozone-tubes. The current and the voltage are measured, and also the temperature and pressure of the gas in the tube.

When pure carbon dioxide or a mixture of carbon monoxide and oxygen (2 vols.:1 vol.) is used, an equilibrium is attained which depends on the voltage used, the temperature, and the distance apart of the electrodes. Only traces of ozone are formed, and the same equilibrium is attained in presence of chlorine, but much more slowly. If excess of carbon monoxide or oxygen is used, either the brown solid formed from carbon monoxide alone or ozone is produced. With about 6000 volts at 20° and the electrodes 1.7 mm. apart, about 14% of the carbon dioxide is dissociated when equilibrium is attained. This increases with increased voltage, and diminishes at higher temperatures and with increased distance apart of the electrodes. The quantity dissociated is from thirty to one hundred times more than would be calculated from Faraday's law, but the free energy of the carbon monoxide and oxygen produced is only from 1.2 to 6.3% of the electrical energy expended in producing the decomposition.

The decomposition of hydrogen chloride is very small (about 1% with 14,000 volts).

Sulphur dioxide and oxygen combine quantitatively to form the trioxide. The yield of sulphur trioxide per kilowatt hour varies from 3.5 to 14.3 grams.

A mixture of hydrogen chloride and oxygen is converted largely (95%) into chlorine and water, 10 to 13 grams of chlorine per kilowatt hour being formed.

T. E.

The Oxygen Electrode. Electromotive Behaviour of the Oxides of Platinum. G. GRUBE (*Zeitsch. Elektrochem.*, 1910, 16, 621—632).—The measurements of the potentials of platinum oxide electrodes made by Lorenz (*Abstr.*, 1909, ii, 463, 640, 857) may be too low, owing to the lack of conductivity of the oxides and to the fact that in one set of measurements the electrodes were yielding a small current. The author has made measurements on electrodes containing several grams of the oxide mixed with graphite and compressed in a perforated platinum foil case. The results, referred to the hydrogen electrode for 2*N*-sulphuric acid at 18°, are: PtO₂.4H₂O, 1.06 volts; PtO₂.2H₂O, 1.04 volts; PtO₂, about 1.5 volts; PtO,

indefinite, about 0.9 volt. An electrode containing the trioxide evolves oxygen continuously, and its potential falls slowly. An electrode of the dioxide when polarised anodically behaves in the same way as one made of the trioxide. A monoxide electrode when anodically polarised possesses, at first, a higher potential than the dioxide, which falls off steadily.

The potential of a platinised platinum electrode after anodic polarisation was followed for two hundred and sixty-two days. It fell quite steadily from 1.5 volts to 1.05, at which point it remained for eight days, then falling to 1.02 volts, where it remained without further change.

It appears, therefore, that potentials from 1.5 volts downwards are due to solid solutions of PtO_3 in PtO_2 , or of PtO_2 in PtO .

Since platinum electrodes can be polarised up to potentials of 2 volts, it appears probable that an unknown tetroxide of platinum may exist.

T. E.

Anodic Behaviour of Molybdenum, Manganese, Chromium, and Tantalum. HANS KUESSNER (*Zeitsch. Elektrochem.*, 1910, 16, 751-772).—A molybdenum anode dissolves quantitatively, with the valency 6, in *N*-potassium hydroxide. The metal used contained a little iron and traces of carbon and oxide, but two different pieces of it behaved differently. One of them became passive when the current density exceeded about 0.05 ampere per sq. cm., whereas the other showed no signs of passivity with very much larger current densities.

With a manganese anode in neutral solutions (of potassium chloride or sulphate), the metal dissolves, and both hydrogen and oxygen are evolved, the whole of the metal finally present in the solution being bivalent. Manganese itself dissolves with evolution of hydrogen, but the rate is too slow to account for the quantities of hydrogen observed; it is, therefore, thought probable that univalent manganese ions are formed which react with the hydrogen ions in the solution thus: $2\text{Mn}^+ + 2\text{H}^+ = 2\text{Mn}^{++} + \text{H}_2$. From 8-10% of the manganese dissolves in this way. The oxygen is evolved when the potential of the manganese anode is more than 0.3 volt more negative than the normal hydrogen electrode, whilst hydroxyl ions could only be discharged directly if it were 1.62 volts more positive; the oxygen is, therefore, a secondary product. The potential measurements show further that the dissolution of manganese accompanied by evolution of oxygen at the anode and of hydrogen at the cathode is a process which takes place of its own accord; hence the gain of free energy due to the conversion of metallic manganese into ions cannot be less than the loss due to the decomposition of water. Following this out quantitatively, it appears that the manganese must dissolve primarily in the form of trivalent ions, which then react with hydroxyl ions, thus:

Increasing the alkalinity of the electrolyte leads to the formation of manganese ions of higher valency in increasing quantity.

A chromium anode in solutions of potassium chloride dissolves with different valencies between 2 and 6. At low temperatures and small

current densities the valency approaches 6; at higher temperatures it falls, but the author could not find any set of conditions in which only one kind of ion is formed. This was equally the case in alcoholic solutions of zinc chloride.

In 16*N*-solutions of potassium hydroxide a tantalum anode is converted into the pentoxide, the electro-chemical valency being 5. The pentoxide forms a layer on the anode which permits a small current to pass. Increasing the applied voltage does not increase this current beyond 0.02 to 0.03 ampere per sq. cm.

T. E.

Migration of Ions in the Water Voltmeter. * FRANZ STREINZ (*Zeitsch. Elektrochem.*, 1916, 16, 744—747).—In Hofmann's voltmeter, in the form commonly used for demonstrating the electrolytic decomposition of water, the sulphuric acid in the cathode tube rises, whilst that in the anode tube falls. The effect is measurable after one hour's electrolysis with 1 ampere or more. The author has compared the rise and fall (due to changes in the density of the acid) in a special apparatus with narrow tubes with those calculated from Hittorf's measurements of the migration of sulphuric acid, and has found a fairly close agreement. The changes of level are, however, larger than those calculated, instead of being smaller, owing to partial equalisation of the densities by diffusion.

T. E.

Electrolysis of the Iodides of the Alkaline Earths Dissolved in Pyridine. GEORG VON ILEVSY (*Zeitsch. Elektrochem.*, 1916, 16, 672—673).—A saturated solution of barium iodide in pyridine contains 20.358 grams per litre at 25°. The conductivity per equivalent at 25° is: $\nu = 9.606$, $\Delta = 8.855$; $\nu = 18.01$, $\Delta = 10.723$; $\nu = 38.59$, $\Delta = 13.045$; $\nu = 81.06$, $\Delta = 15.961$.

When these solutions were electrolysed with platinum electrodes separated by a porous partition, a firmly adherent non-conducting deposit was very soon formed on the cathode. This consisted of barium hydroxide and carbonate, and was due to traces of moisture in the solutions. The pyridine was then dried completely by prolonged electrolysis with 110 volts, but the barium produced by the electrolysis of the dry solutions reacted with the pyridine itself, giving a reddish-brown slime; this was the case even at -40°.

A barium amalgam containing up to 30% of barium may be prepared by electrolysing the dry pyridine solutions with a mercury cathode, the current efficiency being about 80%.

T. E.

Sparking at the Electrodes in the Electrolysis of Molten Salts. ANTON KAILAN (*Zeitsch. anorg. Chem.*, 1916, 68, 141—159).—When molten chlorides are electrolysed with a carbon anode and an iron cathode, the operation is sometimes interrupted by the separation of the mass from the anode, the cessation of the evolution of chlorine, and a rapid fall of the current strength.

It is shown, by measurements of the fall of potential when chlorides are electrolysed, that the effect is not due to the formation of a subchloride, or to the separation of a layer of silica derived from the crucible. The effect is completely inhibited by increase of

temperature, a critical temperature being observed at 500° in a mixture of equal weights of potassium and lithium chlorides, and at about 590° in pure lithium chloride. The addition of lithium bromide hinders the effect. The effect of temperature appears to be connected with the change of viscosity, a conclusion which is confirmed by experiments with dilute sulphuric acid to which glycerol has been added. The effect occurs with a platinum anode as well as with carbon. When the effect is present, the apparent resistance of the cell falls with increasing potential difference. Experiments with an oscillograph show that the variations in the current are very small, provided that the anode dips sufficiently far into the electrolyte. There are about 2000 oscillations in a second. A purely mechanical explanation of the phenomenon is suggested.

C. H. D.

Properties of Salt Solutions in Relation to the Ionic Theory. I. Mol-numbers Derived from the Freezing-point Lowering. ARTHUR A. NOYES and K. G. FALK (*J. Amer. Chem. Soc.*, 1910, 32, 1011—1039).—This paper is devoted to a consideration of the lowering of freezing point caused by acids, bases, and salts, and includes a large number of numerical data collated from the best published observations. The symbol i has been employed to represent the factor by which the number of formula weights, N , associated with 1000 grams of water must be multiplied if the osmotic pressure is to be correctly calculated by the laws of a perfect solution. This has been calculated for several substances in dilute aqueous solution from the simplified equation: $iN = \Delta t / 1.858(1 + 0.0055\Delta t)$, deduced from Washburn's expression (*Tech. Quart.*, 1908, 21, 273); Δt is the lowering of freezing point.

The principal table contains the values of the ratio $\Delta t/N$ (called the formal freezing-point lowering) for forty-two substances, also the weighted mean of several determinations, the best value for the ratio, and finally the mol-number, i , in each case for concentrations between 0.005 and 0.5 equivalent per 1000 grams of water.

The author utilises the results in the discussion of the relation of the mol-number to the type of salt and its variation with concentration.

W. O. W.

Elevation of Boiling Point under Reduced Pressure. KARL DRUCKER (*Zeitsch. physikal. Chem.*, 1910, 74, 612—618).—An apparatus for measuring the elevation of the boiling point under reduced pressure, similar to that used by Rose-Innes (*Trans.*, 1902, 81, 682), is described and figured. As in Beckmann's most recent form of apparatus, electrical heating is used.

The apparatus has been tested with benzene, chloroform, and alcohol as solvents, and camphor as solute with satisfactory results. The observed values of the elevation and those calculated by the van't Hoff formula are in excellent agreement for benzene and for alcohol, but not for chloroform. The experimental value for the latter at 61° is 39.1; in agreement with recent measurements of Beckmann and of Turner (*Trans.*, 1910, 97, 1184), whilst the calculated value at the same temperature is 38.3.

G. S.

Vaporisation in Vacuum. JAROSLAV HLADÍK (*Biochem. Zeitsch.*, 1910, 23, 29—33).—An apparatus is described for the rapid evaporation of solutions under reduced pressure. The vapour is condensed on the inner surface of a cooled bell-shaped vessel, which forms the upper part of the vaporising chamber. The condensed liquid collects in a circular trough which communicates with a collecting bottle outside, through which communication is made with a pump for exhausting the apparatus.

H. M. D.

Binary Solution Equilibria of the Three Isomeric Nitroanilines. ROBERT KREMANN (with J. GEEB and F. NOSS) (*Monatsh.*, 1910, 31, 855—859).—The melting-point curve for mixtures of *o*- and *m*-nitroanilines falls from the melting point of each component to a eutectic point at 47°, the eutectic composition being 66% of *o*-nitroaniline. *m*- and *p*-Nitroanilines give a similar curve, the eutectic temperature being 86°, and eutectic composition 66% of *m*-nitroaniline. Similar results are obtained with mixtures of *o*- and *p*-nitroanilines, the eutectic temperature and composition being 52° and 78% *o*-nitroaniline respectively.

The irregular curves obtained by Tingle and Rolker for these substances (Abstr., 1908, i, 408, 974) are due to the fact that small quantities were used, and the melting points determined by the ordinary method employed in organic chemical practice. T. S. P.

A Simple Distillation Apparatus. F. VOLLRATH (*Chem. Zeit.*, 1910, 34, 1068).—A simple substitute for a condenser is described, consisting of a bottle with double-holed cork, through one hole of which the tube from the distilling flask enters, whilst the other is fitted with a funnel, in which a flask filled with cold water rests.

C. H. D.

Adiabatic Determination of Heats of Solution of Metals in Acids. II. Heat of Dilution of the Acid Solutions. THEODORE W. RICHARDS, ALLEN W. ROWE, and LAURIE L. BURGESS (*J. Amer. Chem. Soc.*, 1910, 32, 1176—1186).—In an earlier paper (this vol., ii, 391) an account was given of a series of determinations of the heat of solution of zinc, aluminium, magnesium, cadmium, and iron in an excess of hydrochloric acid at 20°. In the course of this work, it was found that the heats of dilution, both of the acids and of the residual solutions after the completion of the reactions, affect the results to a considerable extent. In order to reduce to the same standard, it was therefore necessary to carry out experiments on the heats of dilution, and an account of this work is now presented.

The heats of dilution at 25° of the acids $\text{HCl} \cdot 20\text{H}_2\text{O}$ and $\text{HCl} \cdot 8 \cdot 808\text{H}_2\text{O}$ to $\text{HCl} \cdot 200\text{H}_2\text{O}$ were determined, and found to be 0.556 and 1.330 Cal. (or 2.32 and 5.56 kilojoules) respectively. The heats of dilution of the products obtained by dissolving zinc, aluminium, cadmium, and iron in excess of concentrated acid were determined. The substitution of salt for acid was found to affect seriously the heat of dilution, especially in the cases of zinc and cadmium. From these data, the heats of solution of a gram-atom of the five metals in exactly

the theoretical quantity of $\text{HCl} \cdot 200\text{H}_2\text{O}$ have been calculated, and are given in 18° Cals. and also in kilojoules: zinc, 36.6 Cal. or 153.1 kilojoules; aluminium, 127.0 Cal. or 531.0 kilojoules; magnesium, 110.2 Cal. or 460.6 kilojoules; cadmium, 17.2 Cal. or 71.9 kilojoules; and iron, 20.8 Cal. or 87.0 kilojoules. E. G.

Effect of the Glass Surface in Vapour Density Determinations. KARL DRUCKER and G. ULLMAN (*Zeitsch. physikal. Chem.*, 1910, 74, 567—611).—The densities of the vapours of a number of organic compounds at varying temperatures and pressures have been investigated by a modification of the Hofmann method under such conditions that the influence of the glass surface could be determined. The glass surface was varied by using different quantities of glass wool in the interior of the density bulb. The method of measurement adopted is described in detail. The corresponding measurements of Ramsay and Steele (Abstr., 1903, ii, 635) are affected by a considerable error, owing to inaccurate determination of the temperature of the mercury column in the measuring tube.

From the results, the percentage values of pv as compared with that for an ideal gas are calculated and plotted as ordinates against the corresponding pressures as abscissæ. The vapours of benzene, ethyl ether, chloroform, and ethyl alcohol are adsorbed to a small extent on the glass surface, but the adsorption can be neglected for ordinary measurements. Acetic acid, on the other hand, is condensed very considerably; this adsorption is not satisfactorily represented by the ordinary adsorption formula with coefficient less than unity. From the results, the complex constant $k = [\text{bimolecular acid}]/[\text{unimolecular acid}]^2$ has been obtained. At 110°, 95.5°, and 80.2° the values of k are 0.11, 0.25, and 0.60×10^3 respectively. The alteration with temperature is much smaller than that observed by Ramsay and Steele.

Ramsay and Young state that the saturated vapour of acetic acid shows a minimum in the density with change of temperature, but the authors point out that the extrapolation of Ramsay and Young leads to inaccurate values, owing to the influence of adsorption, and that there is no real abnormality of the nature indicated.

The thickness of the layer of acetic acid on the surface of the measuring tube is 0.16—0.60 μ , that of chloroform 0.10—0.20 μ , and that of alcohol only 0.004—0.011 μ . G. S.

van Laar's Theory of the Contraction in Water-Alcohol Solutions. A. G. DOROSHEWSKY and M. S. ROSCHDESTVENSKY (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 442—452. Compare van Laar, Abstr., 1900, ii, 189).—A theoretical discussion of van Laar's theory of the association of liquid molecules, in which the authors conclude that van Laar has given no proof of the fundamental principles underlying his theory. Using van Laar's formula for mixtures of water with propyl and isopropyl alcohols, the contraction of volume of the water, which, according to van Laar, should equal 8.44 at 15.56°, is only 4.67 for the former and 4.79 for the latter; on the other hand, the contraction with ethyl alcohol at 20° is 8.31. Z. K.

Molecular Volumes of Solids. H. H. STEPHENSON (*Chem. News*, 1910, 102, 178—180, 187—189).—Regularity may be traced in the molecular volumes of solids without departing from the atomic volumes of the free elements. Molecular condensation is defined, and shown to be equal for anhydrous salts in each group or sub-group of the Periodic Table for each class of compound, but to vary with the groups and with the acid radicle. The density and molecular volume of any solid compound may, therefore, be calculated if the group condensation is known. The atomic volumes of elements may also be obtained from the density of any of their compounds; for instance, ytterbium has an unknown atomic volume, but its oxide, Yb_2O_3 , has a molecular volume of 43, and the condensation of the sesquioxides of its group is 48, which gives $\text{Yb} = 19.8$, showing a density of 8.7. Hydrated salts, double salts, acid and basic salts, are generally additive in molecular volume, the value for each molecule of water averaging 14. Formulae are given connecting the densities of hydrated and anhydrous salts. It is also shown that the apparent equality of volume of some series of similar and isomorphous salts is due to the fact that they have undergone equal condensation from approximately equal theoretical volumes.

W. P. S.

The Equation of Continuity of the Liquid and Gaseous States of Matter. RICHARD D. KLEEMAN (*Phil. Mag.*, 1910, [v], 20, 665—689).—A mathematical paper in which the expression deduced previously for the attraction between two molecules is made the starting point for the deduction of equations relating to the continuity of the liquid and gaseous states of aggregation. Certain of these relationships are examined by reference to experimental data for various organic compounds.

H. M. D.

Surface Energy and Surface Tension. JAMES E. MILLS and DUNCAN MACRAE (*J. Amer. Chem. Soc.*, 1910, 32, 1162—1176).—Whittaker (Abstr., 1908, ii, 817) has stated that the surface energy of a liquid in contact with its own vapour at any temperature is proportional to the product of the internal latent heat and the absolute temperature. This relation has now been investigated, and found to be only approximately true. It is shown that the relation suggests a division of the so-called surface energy of a liquid into two parts, one due to the liquid surface and the other to the surface of the vapour over the liquid, and this point will be further investigated.

E. G.

Measurement of Surface Tension by the Method of Maximum Pressure of Small Bubbles. R. MAGINI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 184—189).—By the adoption of certain improvements in the experimental arrangements, the author has succeeded in obtaining by this method (compare Cantor, *Ann. Phys. Chem.*, 1892, [ii], 47, 399, 422; Feustel, *Ann. Physik*, 1905, [iv], 16, 61) measurements of the surface tension of benzene, nitrobenzene,

liquid air, and water, with a degree of exactness comparable with that obtained by Rayleigh's wave method (compare Abstr., 1907, ii, 334).

R. V. S.

Surface Tension of Aqueous Solutions and Laplace's Constant. WILLIAM C. McC. LEWIS (*Zeitsch. physikal. Chem.*, 1910, 74, 619—640).—It has already been shown that whilst inorganic salts increase the surface-tension liquid/vapour, they diminish the surface-tension liquid/liquid. In this connexion the surface-tension liquid/vapour has been measured by the dropping method for rosaniline hydrochloride, Congo-red, methyl-orange, methyl-violet, sodium glycocholate, carbamide, malonic acid, and copper sulphate at 14°, 43°, 61°, and 78°. The action of the dissolved substances diminishes gradually as the temperature rises, but in no case has an inversion been observed.

The different effect of inorganic salts in the two cases is discussed and accounted for on the basis of Laplace's theory of internal pressure. Employing instead of the surface-tension, σ , Laplace's capillary factor H_0 , where $\sigma = H_0 \rho^2/2$, ρ being the density, it is shown that H_0 for water is diminished by the addition of all dissolved substances, both at the surface liquid/liquid and at the surface liquid/vapour. With reference to the specific internal pressure K_0 (where $K = K_0 \rho^2$), it is shown that with the exception of those liquids which are completely miscible with water, the addition of any dissolved substance to water diminishes the value of K_0 , whereas, according to Tammann, in the same circumstances, K always increases.

Considering only the surface liquid-vapour, it is shown that the changes of the internal pressure, K , and the surface tension, σ , are always in the same direction. This rule does not apply when the solute is volatile or for certain colloidal solutions.

The considerable diminution of the surface tension produced by certain solutes can be accounted for on the basis of Laplace's theory.

G. S.

The Physico-chemical Theory of Soap Emulsions. Emulsification of Hydrocarbon Oils by Aqueous Solutions of Salts of the Fatty Acids. FREDERICK G. DONNAN and H. E. POTTS (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 208—214).—The influence of the sodium salts of eleven normal fatty acids on the surface tension at the contact surface between water and a nearly acid-free hydrocarbon oil has been investigated. The fatty acids used formed a continuous series from acetic to decolic, and, in addition, lauric and myristic acids were examined. All these salts diminish the surface tension, and the extent of the diminution increases in general with increasing molecular weight of the acid. The action begins to be considerable in the case of sodium octoate, and from this point onwards the influence increases more and more rapidly as the molecular weight increases. In harmony with these observations, it is found that the sodium salts of lauric and myristic acids are the only members of the series which give rise to emulsification effects. In these two cases the emulsification capacity increases rapidly with the concentration of the dissolved salt, and then decreases rapidly at higher concentrations. The existence of this

maximum effect is attributed to the salting-out action of the sodium ions. It is supposed that the changes in surface tension, which are obviously connected with the emulsifying power of certain solutions, are accompanied by changes in the potential differences at the contact surface.

H. M. D.

Autosorption (Auto-adsorption). WILLIAM C. McC. LEWIS (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 197—205).—The views expressed in this paper relating to the nature of the liquid vapour contact surface have been for the most part published previously (compare this vol., ii, 829). The term autosorption is introduced in reference to the greater density of the surface layer of a liquid as compared with its bulk density. Whereas autosorption has been found for a number of liquid organic compounds which have been examined, there appears to be little difference in the surface and bulk densities in the case of the elements mercury, bromine, and iodine. For these substances the autosorption is therefore of very small magnitude, and this appears to be the case for zinc and cadmium.

The surface and bulk densities of water are employed to calculate the difference between the quantity of water actually present in the surface layer of water and that which would be present if capillary forces were eliminated. The value thus obtained is of the order 10^{-6} — 10^{-7} gram per sq. cm.

H. M. D.

Changes in Tanning [Processes]. REGINALD O. HERZOG and GEORG ROSENBERG (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 222—227).—In continuation of previous experiments (*Abstr.*, 1908, ii, 262) on the adsorption of substances from aqueous solution by lightly chromed hide powder, the authors have made similar measurements with non-chromed powder. Aqueous solutions of sodium picrate, silver nitrate, crystal-violet, patent-blue, new-magenta, and phenol were examined. The removal of sodium picrate from aqueous solution takes place in accordance with the simple law of distribution, the value of the exponent in the adsorption formula being equal to unity. With chromed hide powder the proportion of adsorbed substance increases somewhat with the concentration of the solution. In the case of silver nitrate, the data agree with the formula $K = B^m/C$, in which C is the quantity of the adsorbed substance, and B is the concentration of the residual solution, if m is made equal to 0.5. The adsorption of the three colouring matters is also in accord with the exponential equation, but the data for phenol show considerable divergence, and this is considered to indicate that the removal of phenol by the hide powder is not due to a simple adsorption process. An empirical formula is given by means of which the data for phenol can be satisfactorily reproduced.

In general, there is no essential difference in the behaviour of chromed and non-chromed hide powder in regard to their adsorptive properties.

H. M. D.

The Capillary Rise of Acids. ZDENKO H. SKRAUP, E. KRAUSE, and A. VON BIEHLER (*Monatsh.*, 1910, 31, 753—776).—In the case of all organic acids, the regularities which have been previously observed

are confirmed (compare Ahstr., 1909, ii, 868; this vol., ii, 191). The stronger the acid is, the more it is absorbed by the filter paper, and the less is the capillary rise; the weaker it is, the less is the absorption. The large capillary rise with acetic acid is much diminished when it is transformed into trichloroacetic acid; the same result is true for the pairs of acids: succinic and dibromosuccinic; benzoic and nitrobenzoic.

Phosphoric acid has a very small capillary rise, and the suggestion has been made that this is due to its polybasicity. In order to test the validity of this suggestion, measurements have been made with benzene-mono-, di- and tri-sulphonic acids, with different carboxy-acids of benzene, including mellitic acid, and with oxalic, malonic, succinic, glutaric, and tricarballylic acids. It is found that a decrease in the capillary rise does not take place with increase in the basicity of the benzenesulphonic acids; it does take place with the carboxy-acids of benzene, but the decrease stops when the value of the capillary rise becomes the same as that for strong acids. In the case of tricarballylic acid, the capillary rise is greater than that for malonic, succinic, or glutaric acids.

Arsenic acid is similar to phosphoric acid, in that it has an abnormally low capillary rise. Pyrophosphoric acid, in contradistinction to orthophosphoric acid, shows an abnormally high rise, whereas metaphosphoric and phosphorous acids give much lower rises, the rise with the latter acid approximating to that for relatively strong acids. Hydrofluoric acid gives practically the same result as hydrochloric acid, although it is much less dissociated.

Using a modification of Holmgren's circle method, the absorptions of sulphurous and hydrocyanic acids and solution of hydrogen sulphide have been investigated. Hydrocyanic acid has a higher capillary rise than hydrochloric acid, whereas with the other two acids the rises are practically the same as for hydrochloric acid.

The present investigation shows that there are undoubted regularities in the case of organic acids, but with inorganic acids the number of irregularities has been increased.

T. S. P.

Osmotic Equilibrium between Two Fluid Phases. L. GAY (*Compt. rend.*, 1910, 151, 612—616).—A purely mathematical treatment of the subject.

W. O. W.

Relation of Osmotic Pressure to the Intrinsic Pressure of Liquids. M. M. GARVER (*J. Physical Chem.*, 1910, 14, 651—664. Compare this vol., ii, 398).—The intrinsic or internal pressure of a gas in which the molecules exercise no attraction for one another is numerically equal to the extrinsic pressure exercised by the gas on the containing vessel. The intrinsic pressure of a liquid is equal to the extrinsic pressure plus the effect of molecular attractions, and has a different value in the surface film where molecular attractions are not wholly balanced.

The author assumes that the average molecular energy of translation is the same in the gaseous and liquid phases if the molecular

weight (m) is the same, since the mean square of the molecular velocity (v) in either phase represents the absolute temperature.

If p_1 and P_1 are the intrinsic pressures of gas and liquid respectively, $P_1 = \frac{2}{3}(n_1 m v^2)/2 = \frac{2}{3}(n_1 m v^2)/2 \times n_2/n_1 = p_1 \times n_2/n_1$, where n_2 and n_1 are the numbers of molecules per unit volume in liquid and vapour phase respectively. The intrinsic pressure of a liquid is very simply obtained by multiplying the vapour pressure by the ratio of densities of liquid to vapour. Further, it is deduced that $PV = pv = RT$, that is, the gas laws hold for liquids if P is interpreted as intrinsic pressure. If P_1 and P_2 be the intrinsic pressures of a solvent and solution respectively, $P_1 - P_2 = \rho RT \log p_1/p_2$ = the osmotic pressure, where p_1 and p_2 are the vapour pressures of solvent and solution respectively. Osmotic pressure is thus defined as the reduction in intrinsic pressure or normal activity of the solvent due to the introduction of the solute. This reduction is brought about by the reduction of the number of molecules of solvent from N to $(N - n)$, n being the solute molecules. The volume concerned in osmotic calculations is the volume of the solvent multiplied by N/n , whilst the pressure is diminished in the ratio n/N .

The intrinsic pressure of water at 0° is 1235 atm. A weight-normal solution contains 1 molecule of solute to 55.6 of solvent, and its osmotic pressure is therefore $1235/55.6 = 22.2$ atm.

If the membrane is not wetted by the liquid, a surface film exists, which with its unbalanced molecular attractions prevents free circulation of the solvent so that no osmosis occurs. The principal part in osmotic phenomena is played by the solvent, and some form of association hypothesis is necessary.

R. J. C.

Methods of Diffusion Experiments. RAPHAEL E. LIESEGANG (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 219—222).—The nature of the precipitation membranes which are formed when gelatin solutions of silver nitrate and the halogen salts of the alkali metals are juxtaposed is shown to depend on the circumstances in which the diffusion processes take place.

H. M. D.

Inconstancy of the Solubility Product. ARTHUR E. HILL (*J. Amer. Chem. Soc.*, 1910, 32, 1186—1193).—Cameron (Abstr., 1902, ii, 75) has found that the solubility of gypsum is increased by addition of sodium chloride up to a certain concentration, and beyond this point the solubility diminishes. Hill and Simmons (Abstr., 1909, ii, 647) have observed a similar behaviour when silver sulphate is treated with nitric acid solutions. It is shown that this decrease in total solubility can only be accounted for by assuming that the concentrations of the ions of the solute have diminished, and that the value of the solubility product has accordingly been reduced. The work now described was carried out with the object of gaining further evidence on this point.

The solubility of thallous chloride in acetic acid of concentrations between zero and $16N$, and that of tetramethylammonium iodide in potassium hydroxide of concentrations between zero and $8.3N$, has been determined at 25° . Measurements of the conductivity of a

saturated solution of tetramethylammonium iodide and of solutions varying from $N/8$ to $N/1024$ have also been made for use in the calculations. The results show that the solubility of thallous chloride and tetramethylammonium iodide is so diminished in presence of the other electrolytes as to prove conclusively that the solubility product is not a constant, but that it decreases with increase in the total concentration of electrolytes present.

E. G.

Ionisation Relations of Sulphuric Acid. ARTHUR A. NOYES and M. A. STEWART (*J. Amer. Chem. Soc.*, 1910, 32, 1133—1162).—Sulphuric acid is usually assumed to undergo ionisation in aqueous solution according to the equations: $H_2SO_4 = H^+ + HSO_4^-$ and $HSO_4^- = H^+ + SO_4^{2-}$, but the only investigation yielding valuable evidence as to the proportion of the HSO_4^- ion present is that of Noyes and Eastman (*Carnegie Inst. Publications*, 1907, 63, 239). The present work was therefore undertaken with the view of obtaining more definite information with regard to the ionisation of this acid.

The hydrogen-ion concentration, C_H , can be calculated from the value of the mol. number, i , as determined from the depression of the f. p., by means of the relation $C_H/C = i - 1$. The values of C_H/C at 0° have been thus derived from the recorded f. p. data.

It is shown that by combining conductivity and transference data, there can be derived maximum and minimum values of the hydrogen-ion concentration in sulphuric acid corresponding with the two limiting cases in which the only negative ion present is SO_4^{2-} or HSO_4^- , and in this way limiting values of C_H/C at 25° and 0° have been calculated. Incidentally it has been found from a study of existing conductivity data at 0° that the best values for the equivalent conductivity at 0° of certain ions are $\Lambda_K = 40.3$, $\Lambda_{Cl} = 41.1$, $\Lambda_{SO} = 42.8$, and $\Lambda_H = 224$.

The value of Λ_{HSO_4} at 25° and 0° can be approximately calculated from the transference and conductivity data, if it is true that the HSO_4^- ion is present in the sulphuric acid solution in considerable quantity so that its conductivity may enter as a factor. The values obtained are 35—40 at 25° , which are nearly half of that of Λ_{SO} , namely, 79 at 25° .

The values of C_H/C have also been calculated from a consideration of the relative effects of sulphuric and hydrochloric acids on the hydrolysis of sucrose at 25° as determined by Ostwald (*Abstr.*, 1885, 882), and on that of ethyl acetate as determined by Kay (*Proc. Roy. Soc. Edin.*, 1898, 22, 493).

A new isohydric method of determining the hydrogen-ion concentration is described, which consists in determining the relative concentrations of hydrochloric and sulphuric acids which drive back the ionisation of picric acid to the same extent.

The values of C_H/C at various concentrations at 0° and 25° obtained by these different methods are tabulated. In order to derive the concentrations of the HSO_4^- and SO_4^{2-} ions from the values of the hydrogen-ion concentration, Noyes and Eastman (*loc. cit.*) assumed that under corresponding conditions the first hydrogen of sulphuric acid is dissociated to an equal extent to that of hydrochloric acid, and

hence estimated the concentration of the non-ionised sulphuric acid. From this concentration and that of the hydrogen ion, the concentrations of the SO_4 and HSO_4 ions were obtained by subtraction. Similar calculations have now been made, and the results show that both the SO_4 and HSO_4 ions are present in large proportions at medium concentrations, that the latter is present in much larger quantity at 0.05 formal and the former at 0.005 formal, and that at 0.05 formal the ratio $\text{CHSO}_4/\text{CSO}_4$ increases greatly between 0° and 25° . The hydrogen-ion concentration decreases markedly within the same range of temperature.

Experiments have been made on the distribution of sulphuric acid between water and amyl alcohol. The ratio of the concentration of the acid in the alcohol to that in the water was found to increase as the proportion of non-ionised sulphuric acid in the aqueous solution increased. The ratio of this increase is somewhat smaller even than in the case of hydrochloric acid, indicating that the non-ionised sulphuric acid is formed from two ions, H^+ and HSO_4^- , instead of from three ions, H^+ , H^+ , and SO_4^{2-} .

Determinations have been made of the transference of Na, H, and SO_4 during the electrolysis of sodium hydrogen sulphate at 25° . The conductivity of this salt has also been measured at various concentrations at 25° . By combining these data, the concentrations of Na and H ions in a 0.1 formal solution have been calculated, and the values $C_{\text{Na}}/C = 0.68$ and $C_{\text{H}}/C = 0.44$ obtained.

From the results obtained by Kay (*loc. cit.*) on the catalysis of ethyl acetate by 0.1 formal sodium hydrogen sulphate, the value of C_{H}/C has been derived and found to be 0.416.

By means of the values of C_{H}/C and $C_{\text{H}}/C_{\text{Na}}$ derived from the transference and conductivity data, the concentrations of the other ions in a 0.1 formal solution of sodium hydrogen sulphate have been computed, and found to be $C_{\text{HSO}_4}/C = 0.44$ and $C_{\text{SO}_4}/C = 0.34$ respectively.

From these data, and also from the corresponding data for 0.05 formal sulphuric acid, the values of the product $C_{\text{H}}\text{CSO}_4/\text{CHSO}_4$, the ionisation constant of the second hydrogen of the acid, have been found to be 0.034 and 0.031 respectively. E. G.

Hydrolysis of Cyanogen. R. NAUMANN (*Zeitsch. Elektrochem.*, 1910, 16, 772—778).—The conductivity of potassium cyanate solutions is measured; the mobility of the cyanate ion at 18° is 56.5. When cyanogen is passed into aqueous solutions of potassium hydroxide, the conductivity diminishes to a constant value. The observed conductivity agrees well with that calculated on the assumption that cyanide and cyanate are the only products. The conductivity of solutions of cyanic acid at 0° is measured, and the dissociation constant found to be about 120×10^{-6} . When cyanogen is passed through water at 0° , the conductivity increases to a constant value, owing to the formation of cyanic acid (the hydrocyanic acid is practically a non-conductor); the saturated solution contains 0.221 gram-molecule of cyanogen and 0.00005 gram-molecule of cyanic acid per litre, so that 0.023% of the cyanogen is hydrolysed. At the ordinary temperature, the conductivity

of water through which cyanogen is passing depends very much on the rate of the current of gas, and it diminishes rapidly when the gas is stopped. This is due to the decomposition of the cyanic acid into ammonia and carbon dioxide. Cyanogen has, therefore, no definite solubility in water at 18°, the quantity absorbed increasing continuously with the time of contact.

In the calculation of the dissociation constant of hydrocyanic acid (this vol., ii, 386) a serious error was made, the correct value is $\log_{10} K = -29.13$ instead of -10.14 . This new value is not in harmony with the view that the *E.M.F.* of the hydrogen-cyanogen element is due to the formation of hydrocyanic acid.

• T. E.

Electrochemistry of Proteins. II. Dissociation of Basic Caseinogenates of the Alkaline Earths. T. BRAILSFORD ROBERTSON (*J. Physical Chem.*, 1910, 14, 601—611. Compare this vol., ii, 679).—It is probable, since the neutral and basic caseinogenates of the alkalis obey Ostwald's dilution law, that a molecule of caseinogenate gives only two ions. The cation is supposed to be a complex ion containing the metal in a non-dissociable form. On this hypothesis basic calcium, strontium, and barium caseinogenates, instead of dissociation into three ions, one of which would be the metal, should give only two complex ions, and the dissociation should obey Ostwald's law.

The solutions examined contained 1 gram of caseinogen to 80×10^{-5} gram-equivalents of calcium, strontium, and barium hydroxide; they were practically neutral to phenolphthalein. The conductivity-dilution curve is in accord with Ostwald's law for a binary electrolyte. If v_1 and v_2 are the ionic velocities and ρ the number of molecules of caseinogenate formed from one molecule of base, the values of $\rho(v_1 + v_2)$ are about twice as great for the caseinogenates of the alkalis as for the alkaline earths. As all the ions concerned are supposed to be complex protein ions, $\rho(v_1 + v_2)$ must be much the same in all the salts. Hence ρ may be taken as two for the alkalis, and one for the alkaline earths. The simplest formula of sodium caseinogenate is $[\text{NaX}'' + \text{X(OH)}_n]'$, and of calcium caseinogenate,

each ion having twice as many charges as there are molecules of base per molecule of caseinogen.

The values of $(v_1 + v_2)$ are about 40×10^{-5} at 30°. This is approximately the value calculated by Bredig as the minimum which ionic mobility approaches when the ions become very large. The caseinogenates of the alkalis are nearly completely dissociated, whilst calcium caseinogenate is only 57% dissociated.

The freezing-point determinations of Robertson and Barnett (*Abstr.*, 1909, i, 447) are explainable on the hypothesis that caseinogenate ions are quadrivalent, so that the sodium salt is written:

This formula suggests that two CO_2H groups of the caseinogen molecule are active in the neutralisation of bases.

R. J. C.

Influence of the Degree of Dispersity of a Solid Crystal on its Melting Point. P. P. VON WEIMARN (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 205—208).—A theoretical paper in which the author analyses

the relationships involved in the transition from the liquid to the amorphous and crystalline solid states of aggregation. H. M. D.

A General Theory for Obtaining Disperse Systems by the Dispersion Method. P. P. VON WEIMARN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 453—474. Compare Abstr. 1909, ii, 132, 221, 306, 606, 646).—A more detailed theoretical discussion of matter already published, and a classification of the methods of peptization. All the dispersion methods of obtaining disperse systems can be explained according to one general theory, the fundamental general principle of which can be formulated thus: If for some reason or other the intensity of the forces of solution at the surface of disperse particles increases to an extent not greater than that at which the velocity of recrystallisation becomes considerable, then the disperse particles are peptised by the dispersion medium. For an explanation of the theory, the paper itself must be consulted. Z. K.

Colloidal Chemistry. A General Introduction. P. P. VON WEIMARN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 476—480).—A short historical and theoretical introduction to the two following papers. A good general method of obtaining any solid substance in the state of an amorphous solid solution of any degree of dispersion has been devised, and is based on the rapid cooling of a dilute liquid solution of a substance in a dispersion medium, which, in the pure state itself, solidifies to a glass when rapidly cooled.

The best method of obtaining liquid colloidal solutions is based on the rapid condensation of the molecules of the dissolved substance, when the solvent is replaced by a dispersion medium which dissolves the solvent, but, practically, does not dissolve the dissolved substance. If a concentrated solution is added to such a dispersion medium, fine disperse precipitates are obtained, but not colloidal solutions. Z. K.

A Simple General Method for Obtaining Solid Colloidal Solutions of any Degree of Dispersion. P. P. VON WEIMARN and J. B. KAGAN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 480—484. Compare preceding abstract).—When a transparent solid solution is heated gradually, the viscosity of the dispersion medium decreases, whilst the velocity of the molecules and molecular aggregates and the coefficient of diffusion increases; consequently, at first, when L in the formula $W = K(Q - L)/L$ (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 214—228) has not yet increased appreciably, the condensation process occurs, and a bluish-violet opalescence appears, which becomes more and more marked until the solution becomes turbid. When L has increased sufficiently, the dispersion process commences, which is indicated by a diminution in the turbidity of the solution, and by a gradual re-appearance of the bluish-violet opalescence, which then gradually disappears.

When a 0.04% solution of sulphur in alcohol is immersed in liquid air, a solid, strongly opalescent, but partially transparent suspended solution is obtained, which, when heated and well shaken, only shows

the second, the dispersion, process described above. With a 0.02% solution of sulphur a wholly transparent solid solution is obtained, which behaves entirely in accordance with the above theoretical scheme. The solution can be fixed or arrested at any stage of opalescence, or at any degree of dispersion, by rapidly immersing the tube containing the solution at the given stage in liquid air. By employing very dilute solution of sulphur, molecular dispersed solid solutions are obtained, in which, when heated, the condensation process is so rapidly followed by the dispersion process that opalescence can sometimes scarcely be observed. Exactly similar results were obtained with phosphorus, sodium bromide, and sodium and potassium chlorides.

A 0.25% solution of phosphorus in alcohol gives a turbid glass; 0.05–0.04% solution yields a partly transparent suspended solid solution, whilst 0.025% gives a wholly transparent suspended solid solution.

Z. K.

A Simple Method of Obtaining Sulphur, Selenium, Tellurium, and Phosphorus in a Colloidal State. P. P. von WEIMARN and B. V. MALJISHEFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 481–487. Compare two preceding abstracts).—Five to twenty-five c.c. of a solution of the metal, saturated at the ordinary temperature or at the boiling point of the solvent (alcohol for sulphur and phosphorus, carbon disulphide for selenium), are rapidly added to 1000 c.c. of the dispersion medium and stirred vigorously. The dispersion medium for sulphur and phosphorus was cold water; for selenium, cold ether. The concentrations of these suspended solutions varied within the limits of several 1/10,000's to several 1/100's, the solutions in the latter case being very turbid and rapidly coagulating.

The solid solutions are coloured, opalescent, and fairly stable, the stability of the phosphorus and selenium solutions depending on the peptisation processes.

This method of obtaining colloidal solutions is recommended for lecture experiments. The probable solubility of selenium in carbon disulphide is 0.02–0.015 gram in 100 of solvent.

Colloidal tellurium is obtained by adding 0.1 of the element to 5 c.c. of a boiling solution of potassium hydroxide, saturated at the ordinary temperature, and adding the solution of the metal thus formed to 1000 c.c. of cold water, the mixture being stirred vigorously. The stability of the colloidal tellurium solution depends directly on the peptisation processes, and can be greatly increased. The solution can also be made more stable by the addition of gelatin or similar substances.

Z. K.

Phenomena of the Colloidal State. PAUL ROHLAND (*Biochem. Zeitsch.*, 1910, 28, 53–55).—Observations relating to the behaviour of adsorbed substances are referred to as showing that substances in the colloidal condition are frequently much less reactive than they are in the crystalloidal form. The viscosity of colloidal substances is very often increased or decreased by special types of ions.

H. M. D.

The Purification of Colloids by Dialysis. RICHARD ZEIGMOND and R. HEYER (*Zeitsch. anorg. Chem.*, 1910, 68, 169—187).—A comparison of parchment, collodion, and fish-bladder membranes in the dialysis of colloidal silica, shows that the last-named acts most rapidly. Collodion membranes, which are perfectly impervious to colloidal silver, allow silica to pass with considerable ease. Continuous renewal of the water in the outer vessel has no advantage over a renewal every two hours. With a suitable membrane, the chlorine is reduced to the limit of recognition by means of silver nitrate in about twenty hours.

An improved dialyser is described, in which a membrane is stretched over a vulcanite ring, placed on a vulcanite tray with edges only 4 mm. high, and provided with radial ribs. The water enters at the centre of this tray, and travels radially in a thin sheet, escaping at the circumference. This appliance allows of rapid dialysis.

In order to estimate chlorine in colloidal solutions of silica, the free hydrochloric acid is first estimated by titration with $N/100$ -sodium hydroxide. Another quantity is then exactly neutralised with sodium hydroxide, a drop of 5% potassium chromate solution is added, and the chlorine is titrated with $N/100$ -silver nitrate. A standard solution may be used for comparison. Under these conditions, 0.01 c.c. of $N/100$ -silver nitrate, run in from a graduated capillary pipette, produces a distinct change of colour, and it is possible to detect 0.004 mg. of chlorine in 1 c.c. of the dialysed liquid. The dialysis, however, proceeds beyond this limit, and it is necessary to employ JORDIS' method (this vol., ii, 416) of distillation with sulphuric acid. The residue obtained after neutralising 100 c.c. and evaporating to dryness is transferred to a small distilling flask, 0.5 to 1 c.c. of concentrated sulphuric acid is added after closing the apparatus, and the distillation is continued until nearly all the sulphuric acid has passed over. The chlorine in the absorbing liquid is estimated by RICHARDS' nephelometric method (Abstr., 1904, ii, 287) by means of silver nitrate.

The precipitation of silver chloride is not hindered by the presence of colloidal silica, unless the latter is in very large excess. If some sulphuric acid is present, the precipitation is in all cases normal.

Sodium sulphate is much less readily removed from silica by dialysis than chlorides. Alumina and iron, derived from the sodium silicate used, are not eliminated. Minute quantities of hydrochloric acid increase the stability of the colloid, sodium hydroxide at first diminishes it, but subsequent additions increase the stability.

The Binary System Pyridine-Potassium Thiocyanate. KARL L. WAGNER and ERNST ZERNER (*Monatsh.*, 1910, 31, 833—841).—The course of the fusion and solubility curves of two substances between the melting and eutectic points has been thoroughly studied only for the case that the mutual solubilities of the two substances decrease with falling temperature. The temperature-concentration diagram for fusions containing the two substances is then the ordinary curve with two branches, neither of which shows a minimum, and one eutectic point. When the solubility of one substance in the other passes through

a minimum there are four cases which are theoretically possible, and for which the authors give the curves. One of these is where the two branches of the fusion curve intersect below the minimum in an eutectic point. The system pyridine-potassium thiocyanate partly conforms to this type, differing from it in that between the eutectic point and the melting point of the potassium thiocyanate there is a four-phase invariant system, namely, liquid pyridine-liquid potassium thiocyanate-solid potassium thiocyanate-vapour. The mutual solubility of the two liquid phases increases as the temperature falls.

The various points on the curves were obtained by heating together weighed quantities of pyridine and potassium thiocyanate in sealed tubes, and observing the temperature at which the crystals disappear or are deposited.

The eutectic temperature is approximately -43.3° , the mixture containing 3.1% of potassium thiocyanate. The four-phase system is formed at 188.5° .

Potassium thiocyanate has m. p. 173.8° .

T. S. P.

Influence of Substitution in the Components on the Equilibrium in Binary Solutions. IV. Phenol and the Methylcarbamides. ROBERT KREMANN [with J. DAIMER, F. GUGL, and H. LIEB] (*Monatsh.*, 1910, 31, 843-853. Compare Abstr., 1907, i, 912).—The melting-point curve for mixtures of phenol and *o*-dimethylcarbamide falls from the melting point of the dimethylcarbamide to a break at $25-25.5^{\circ}$, and then to a eutectic point at 9° , representing mixtures containing 63% and 84% of phenol respectively. The break at 25° is due to the separation of the compound formed from one molecule of each of the components, the composition of the compound being determined by measuring the times of arrest for mixtures varying in composition from 0-63% phenol. The eutectic is a mixture of this compound with phenol.

The curve obtained for mixtures of phenol and monomethylcarbamide is similar in character, the break occurring at 8° and the eutectic at -7° representing mixtures containing 60% and 77% of phenol respectively. The break at 8° is again due to the separation of a compound containing one molecule of each of the components.

The curve for mixtures of phenol and *s*-dimethylcarbamide is the ordinary one for a two-component system giving one compound and two eutectics. The compound is formed from two molecules of phenol and one molecule of dimethylcarbamide, and has m. p. 14° . The eutectic temperatures are $+5^{\circ}$ and -3° , representing mixtures containing 81% and 47% of phenol respectively.

The above results support the statement that asymmetric substitution diminishes the power to form compounds, whereas symmetrical substitution does not have this effect (compare Abstr., 1906, ii, 268).

T. S. P.

Equilibrium between Solid Cuprous Iodide and Aqueous Solutions Containing Cupric Salt and Iodine. WILLIAM C. BRAY and G. M. J. MACKEY (*J. Amer. Chem. Soc.*, 1910, 32, 1207-1214).—The results described in this paper are the outcome of a study of the law of the mass-action in dilute aqueous solutions.

Cuprous iodide is only slightly soluble in water, but in the presence of iodine a considerable amount dissolves, owing to the formation of cupric iodide and tri-iodide. The following equilibria are involved: $\text{CuI(solid)} + \frac{1}{2}\text{I}_2 = \text{Cu}^{++} + 2\text{I}^-$ and $\text{I}_2 = \text{I}_3 + \text{I}^-$.

Values have been determined at 25° under widely different concentrations for the former equilibrium. The ionic concentrations in the various mixtures were calculated by means of the relations derived from conductivity measurements. The values obtained for the equilibrium function $K' = (\text{Cu}^{++})(\text{I}^-)^2/\text{I}_2$ show that this equilibrium conforms with the law of mass-action only as far as the influence of iodine is concerned and deviates from it when cupric salt, iodide, or other salt is added. In all cases, however, the deviations are of such a nature that K' increases with increasing concentration. This result is an illustration of the rule that when the concentration of an ion is based on conductivity measurements, the ratio of its "activity" (Lewis, *Abstr.*, 1908, ii, 16) to its concentration decreases somewhat with increasing ion concentration. From this rule it follows that the solubility product of a salt will not be constant, but will increase with increasing ion concentration.

Values have also been calculated for the equilibrium function, $K = (\text{I}^-)(\text{I}_2)/(\text{I}_3)$. The results confirm the conclusion (this vol., ii, 820) that K decreases with increasing concentration of iodide, but that other salts do not produce a similar effect.

Conductivity determinations made with several of the equilibrium solutions have shown that cupric iodide and tri-iodide are ionised to the same extent as magnesium chloride, and that cupric nitrate is ionised to a somewhat smaller extent. E. G.

Equilibria in the Precipitation of Metals by Hydrogen Sulphide. LUDWIK BRUNER and J. ZAWADSKI (*Bull. Acad. Sci. Cracow*, 1909, 267—312).—The precipitation of thallium sulphide by hydrogen sulphide is a reversible reaction. Measurements in solutions of different acid and hydrogen sulphide concentrations show that at 25°, $K = [\text{Ti}^{++}][\text{H}_2\text{S}]/[\text{H}^+]^2 = 0.637$. The equilibrium has also been approached from the other side by adding thallium sulphide to sulphuric acid and passing hydrogen sulphide. Measurements at 0° and 40° lead to values for the equilibrium constant from which a value for the heat of precipitation of thallium sulphide is obtained by van't Hoff's equation, in agreement with that derived from thermochemical data.

The values of K obtained for the precipitation of ferrous sulphide vary, owing to experimental difficulties, but lie between 2.7×10^8 and 9.1×10^8 . Calculations are made of the solubility products of iron, cadmium, and lead, and the results of previous observers for these and other sulphides are discussed and criticised. It is shown that the published values for the solubility of sulphides in pure water, calculated from the electrical conductivity, are not in accordance with the analytical behaviour of the metals.

The results from thallium sulphide are employed to calculate the electrolytic potential of sulphur. The experiments with lead sulphide lead to a result in close agreement with this. From the potential thus

obtained, the solubility products of the sulphides are calculated by means of Bodländer's formula, and values are obtained in good agreement with the experimental results, with a few exceptions. The observed solubilities are then used to calculate the heat of formation of the sulphides, in good agreement with Thomsen's results.

C. H. D.

Equilibria in the Precipitation of Metals by Hydrogen Sulphide. LUDWIK BAUNER and J. ZAWADSKI (*Zeitsch. anorg. Chem.*, 1910, 67, 454—455).—Owing to differences in the methods of expressing concentrations in the data from different sources, there are certain numerical errors in the authors' calculations (see preceding abstract). The corrected value for the potential of sulphur against the hydrogen electrode is $E_h = +0.545$. Employing this value to calculate the solubility constants, and adopting more recent values for the electrolytic potentials of iron and silver, the agreement between the calculated and observed values is improved. The imperfect agreement in the case of zinc is attributed to the known transformation of βZnS into the less soluble αZnS .

C. H. D.

Equilibria in the Action of Potassium Hydroxide on Mercuric Bromide and Chloride. WALTER HERZ (*Zeitsch. anorg. Chem.*, 1910, 68, 165—168).—In the reaction: $\text{HgBr}_2 + 2\text{KOH} \rightleftharpoons \text{HgO} + 2\text{KBr} + \text{H}_2\text{O}$, the constant $[\text{HgBr}_2][\text{KOH}]^2/[\text{KBr}]^2$ is found to have the average value 10.1×10^{-4} . Basic salts are, however, also formed. The reaction of potassium bromide with an excess of mercuric oxide (Bersch, Abstr., 1891, 1413; Bugarszky, Abstr., 1893, ii, 450, 566) gives a constant 15×10^{-4} .

The precipitation of mercuric chloride by an excess of potassium hydroxide has also been measured in two concentrations. C. H. D.

Kinetics of the Formation of Ethyl Ether from Alcohol and Ethyl Hydrogen Sulphate. ROBERT KREMANN (*Monatsh.*, 1910, 31, 671—683).—The rate at which the reaction between ethyl alcohol and ethyl hydrogen sulphate proceeds at 100°, 125°, and 135° has been determined by measuring the increase in acidity during the course of the reaction. The increase in acidity is not a direct measure of the extent to which the reaction has taken place, since the sulphuric acid formed enters into reaction with the alcohol to re-form ethyl hydrogen sulphate according to the equilibrium reaction: $\text{EtOH} + \text{H}_2\text{SO}_4 \rightleftharpoons \text{EtSO}_3\text{H} + \text{H}_2\text{O}$. At the temperature of experiment this equilibrium adjusts itself practically instantaneously, and since the equilibrium constant has been previously determined (this vol., ii, 700), the correction to be applied to the observed increase in acidity in order to obtain a correct measure of the velocity of reaction can be determined.

The alcohol was always in large excess, and the reaction is assumed to be bimolecular, a number of simplifications having to be made in order to reduce the differential equation to a form in which it can be readily integrated.

The values obtained for the velocity constant are not even approximately constant, but decrease very considerably during the

course of the reaction, the rate of decrease being the greater the greater the initial concentration of the ethyl hydrogen sulphate. This is probably due to the retarding effect of the water formed by the action of the alcohol on the sulphuric acid.

A comparison of the times necessary for the reaction to proceed to the same extent at different temperatures gives a temperature quotient of 2.5 for 10° .

The ordinary method for making ether is discussed in the light of the results obtained.

T. S. P.

The Mechanical Vibration of Atoms. WILLIAM SUTHERLAND (*Phil. Mag.*, 1910, [vi], 20, 657—660).—On the assumption that the atoms of an element may be replaced by cubes of uniform density, having the same mass as the atoms, and just large enough to circumscribe them, the author calculates the wave-lengths corresponding with the fundamental mechanical vibrations of the atoms of the alkali metals and the halogens. It is shown that the wave-lengths corresponding with the vibration of the molecules of the alkali halogen salts are probably represented by the sums of the wave-lengths of the constituent elements. When the computed wave-lengths for sodium chloride, potassium chloride, bromide and iodide are compared with the lengths of the longest infra-red waves examined by Rubens and Mollnagel in the case of these four substances, it is found that a nearly constant ratio of eight is obtained. According to this, the calculated mechanical period of vibration is only three octaves below the lowest period experimentally investigated in each of these four cases.

H. M. D.

New Proof of the Existence of Molecules. THE SYEDBERG and NILS PIHLBLAD (*Zeitsch. physikal. Chem.*, 1910, 74, 513—536. Compare Abstr., 1909, ii, 277, 561, 723).—The relationship between the absorption in a colloidal solution and the size of the particles has been further investigated. Some of the measurements were made with a Vierordt spectrophotometer and a light source giving a continuous spectrum, but the later and more accurate measurements were made with a König-Martens spectrophotometer with homogeneous light.

The results are expressed in terms of $k = \frac{1}{d \log_e} \log \frac{I_0}{I}$ or $k_m = k/\text{mol.}$ per litre, where I_0 and I represent the intensities of the light before and after traversing the absorbing layer, and d is the thickness of the absorbing layer in cm.

A series of solutions of colloidal gold containing particles of different magnitude have been prepared, and it is shown that the wave-length for maximum absorption diminishes progressively as the size of the particles diminishes, whilst the maximum value of k_m increases at first, attains a maximum, and finally diminishes with progressive diminution in the size of the particles. When a solution of phosphorus in ether is added to a solution of chlorauric acid, HAuCl_4 (the absorption maximum of which is in the ultra-violet), the absorption spectrum is at first displaced a little towards the ultra-violet, and then a slow continuous displacement towards the visible spectrum occurs. The

change from gold solutions with a known degree of dispersion (size of particle) and absorption in the visible region to chlorauric acid (with molecular dispersion and maximum absorption in the ultra-violet) is continuous.

Examination of solutions of colloidal and dissolved selenium confirms the above results; in this case the maximum absorption of the molecular solution (in carbon disulphide) lies in the visible region. Some observations with iodogotin solutions are also described.

A relationship has been found between the absorption exerted by each particle and the degree of dispersion.

A Simplified and Improved Form of Toepler's Mercury Air-Pump. ANDREAS VON ANTROPOFF (*Chem. Zeit.*, 1910, 34, 979).—The throwing up of mercury in the Toepler pump is avoided in this form by placing the cylindrical vessel in an inclined position. The vessel need not have a capacity of more than 100 c.c. It is drawn out into a conical form at its upper end, at the junction with the capillary. The pump may be worked rapidly without injury, and is very simple in construction.

C. H. D.

New Modification of the Kipp Gas Generator. F. ALEX. McDERMOTT (*J. Ind. and Eng. Chem.*, 1909, 1, 811—812).—The paper contains a sketch and description of a modification of the Kipp gas generator, in which the base is made cylindrical with a dome-shaped top and in two portions, which fit together with a ground joint; an indentation encircles the inside of the cylinder at a convenient distance from the bottom, and carries a perforated porcelain or lead tray to carry the active material; it has a hole in the centre through which the stem of the acid reservoir passes in the usual manner.

The advantages claimed for this apparatus are: (1) accessibility of all parts for cleaning and recharging; (2) stability, as it is not so tall as the usual forms; (3) an even distribution of the active material over a relatively large area.

F. M. G. M.

Weighing. OTTO KUHN (*Chem. Zeit.*, 1910, 34, 1097—1098, 1168—1169).—Neglect to reduce the weighings of crucibles and other chemical apparatus to the weight in a vacuum may cause an error of several tenths of a milligram if the atmospheric conditions vary between two weighings. The correction should therefore be made in analytical work. Double weighing should be employed in order to eliminate errors due to unequal expansion of the arms of the balance.

C. H. D.

Inorganic Chemistry.

The Molecular Weight of Water in Different Solvents.

GIUSEPPE BRUNI and M. AMADORI (*Gazzetta*, 1910, 40 ii, 1-8).—Water is not sufficiently soluble in any hydrocarbon to permit of cryoscopic measurements, but a number of other solvents which might be expected to cause association have been examined. In each case the degree of association increases with the concentration, being very near to 1 in dilute solutions in bromoform, ethylene bromide, dimethyl-aniline, *p*-toluidine, methyl oxalate, methyl succinate, and veratrole. Alcohol, phenol, and acetic acid are associated in the same solvents, ethylene bromide having the greatest effect and methyl succinate the least. Alcohol and phenol, like water, form single molecules in dilute solution, but acetic acid is associated even in very dilute solution in ethylene bromide. C. H. D.

Direct Synthesis of Volatile Hydrogen Compounds.

ALEXANDER CH. YOUNASOS (*Ber.*, 1910, 43, 2272-2274).—Not only can phosphorus, arsenic, antimony, and sulphur be transformed into their hydrides by heating with sodium formate, but also other elements, especially those which are volatile, and various compounds. The less volatile a substance is, the more difficult it is to reduce it.

If a compound is made up of two volatile components, both are reduced, giving the two hydrides; this is the case with the sulphides of phosphorus, arsenic, and antimony, and the phosphides of arsenic and antimony. If only one component is volatile, that alone is hydrogenised; for example, the phosphides, sulphides, arsenides, antimonides, selenides, and tellurides of the metals. A large number of chloro-, bromo-, iodo-, and fluoro-derivatives, especially those of the heavy metals, give the corresponding halogen hydrides. Nitrides of the metals give ammonia. Silicides, borides, and carbides are not reducible.

Selenium and tellurium form the hydrides when heated with sodium formate to 400°; the yield is limited, owing to the reverse reaction (decomposition) which takes place.

Hydrogen silicide is formed to a slight extent when an equimolecular mixture of amorphous silicon and sodium formate is heated at 1300°. The reaction takes place more readily when the silicon is dissolved in aluminium (2 parts of silicon to 60 of aluminium) and the temperature kept at 750°. Hydrogen boride is formed when the silicon is replaced by amorphous boron (1 part of boron to 25 parts of aluminium); it also results when a mixture of boron with sodium formate is heated in the electric arc. T. S. P.

Some Analogies between Derivatives of Oxygen and Nitrogen. ANGELO ANGELI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 94-101. Compare this vol., ii, 844).—The author amplifies and

extends the views put forward in the former paper as to the analogy displayed in many of their reactions between hydrogen peroxide, hydroxylamine, hydrazine, etc.

R. V. S.

Decomposition of Ozone by Ultra-violet Light. EVA VON BAHR (*Ann. Physik*, 1910, [iv], 33, 598—606).—When ultra-violet light from a quartz-mercury lamp is allowed to fall on ozonised oxygen, the ozone is decomposed. The rate of decomposition increases rapidly as the pressure on the gas is reduced. For a given intensity of the incident ultra-violet radiation, the ozone disappears at a rate which agrees with the requirements of the equation for a unimolecular change, if the pressure is kept constant. The velocity constant is nearly independent of the pressure when this exceeds 200 mm. of mercury, but for lower pressures the constant increases rapidly as the pressure falls.

In consequence of the decomposing action of ultra-violet light, the measurement of the absorption of ultra-violet radiation cannot be applied to the estimation of ozone at low temperatures. H. M. D.

Ozone. V. The Development of Heat in the Decomposition of Ozone. ANTON KAILAN and STEPHAN JAHN (*Zeitsch. anorg. Chem.*, 1910, 63, 243—250. Compare Abstr., 1909, ii, 37).—The oxygen, containing 10% of ozone, is led through a decomposition tube containing soda-lime, enclosed in a vacuum vessel as calorimeter containing water. A manganin spiral is also provided for heating the apparatus electrically in order to calibrate it. With this apparatus, a rise of temperature of 0.2° in ten to fifteen minutes may be measured to 0.001° . The corrected value for the development of heat in the decomposition of ozone at constant volume is 31,500 cal. per gram-molecule.

Experiments with other catalytic agents show that platinum-black gives high values, and rapidly loses its activity. With a heated platinum wire, which is easily calibrated, the concordant value 34,000 cal. per gram-molecule is obtained.

C. H. D.

New Hydrogen Sulphide Apparatus. STEFAN URBASCH (*Chem. Zeit.*, 1910, 34, 1040—1041).—The apparatus may be used in the laboratory room close to a fume chamber without causing any inconvenience whatever, and, owing to the high pressure, several solutions may be treated simultaneously with hydrogen sulphide.

A holds 5 litres, B altogether 6 litres, C altogether 4 litres, D also 4 litres. When used for the first time, B is filled with water, and a glass tube reaching to the bottom is introduced. C contains iron sulphide, D dilute hydrochloric acid (2:1). Hydrogen sulphide is now passed until the water in B is quite saturated, and the apparatus is then fitted up as shown in the figure. If the gas is wanted first, stopcock *f* and then stopcock *g* are opened, causing the acid to flow from D to C. The gas evolved enters by the tube *a* into B, passes through the water, and by means of the tube *b c* and stopcock *g* then passes through the solution to be tested. The gas current is easily regulated, and the spent acid is drawn off from the bottom of C. If saturated

hydrogen sulphide water is required, it is allowed to drain from the burette, and the volume may thus be measured. Owing to the difference in level, fresh water flows from *A* into *B* until the former height has been again reached, and this water becomes again saturated with hydrogen sulphide. Not until 5 litres of hydrogen sulphide water have been used is there any need for replenishing the contents of *A*. During the passing of the gas, the siphon is closed, as otherwise a little of the solution might find its way into *A*. When no gas but only the solution is required,

no fresh water is introduced into *B*; the contents last a long time and cannot deteriorate. In order to empty the burette when the siphon is closed, it is necessary to open the pinchcock *f* for a moment. *B* is made of dark glass so as to prevent any decomposition by light.

L. DE K.

The Constitution of Weber's Acid. KONRAD W. JURISCH (*Chem. Zeit.*, 1910, 34, 1065—1066).—Objections are brought forward against the validity of the ordinary structural formulae for sulphuric acid and nitrosylsulphonic acid. The former is regarded as an additive compound of sulphur trioxide and water, and the latter as

Thermochemical reasons are given for supposing that the group SO_3 is present in both compounds, and that hydroxyl groups are absent.

C. H. D.

Action of Crushed Quartz on Nitrate Solutions. HARRISON E. PATTEN (*J. Physical Chem.*, 1910, 14, 612—619).—A filter bed was made with fine quartz flour of 740 sq. cm. area per gram, which was

washed with hydrochloric acid and distilled water. On percolating through it an 0.01*N*-solution of silver nitrate sterilised with chloroform, some silver remained on the quartz in an insoluble condition, and the filtrate contained upwards of 1% of nitrite calculated as silver nitrite. The silver remaining on the quartz, which was perhaps in the form of silver oxide or silver silicate, was soluble in ammonia, but the percolated silver nitrate was not tested for acidity.

The reduction of nitrate decreases as the adsorptive capacity of the quartz surface becomes satisfied. Sodium nitrate under sterile conditions is not reduced in contact with quartz to give any substance oxidisable with permanganate. The looser combination and the greater hydrolysis of the heavy metal nitrates may facilitate their reduction by quartz.

R. J. C.

The Hydration of Metaphosphoric Acid. D. BALAREFF (*Zeitsch. anorg. Chem.*, 1910, 63, 266—268. Compare this vol., ii, 607).—Although it is not found possible, on account of the volatility of metaphosphoric acid, to reach the temperature at which orthophosphoric acid would pass directly into the meta-acid, it is found that metaphosphoric acid in aqueous solution becomes directly hydrated to form the ortho-acid, without any intermediate formation of pyrophosphoric acid.

C. H. D.

Synthesis of Hydrogen Arsenide from its Elements. ALEXANDER CH. VOURNASOS (*Ber.*, 1910, 43, 2264—2272).—Dry nascent hydrogen, as prepared by heating sodium formate, readily combines with certain of the metalloids to form the hydrides of these elements (compare this vol., ii, 236). Hydrogen arsenide may be obtained by passing the vapours of arsenic heated to 460° over sodium formate contained in a tube heated to a temperature just below the decomposition point of the formate. The heat of the arsenic vapour completes the decomposition, and a mixture of hydrogen and hydrogen arsenide is obtained. The reaction is carried out much more conveniently by heating a mixture of three parts of powdered arsenic with eight parts of dry sodium formate rapidly to 400° in a round-bottomed flask. Yields of 12—17 volume % of hydrogen arsenide have been obtained.

Instead of using sodium formate alone, it is better to use an equimolecular mixture of sodium formate and sodium hydroxide or lime to prepare the nascent hydrogen, as this prevents the formation of sodium oxalate, and hence of carbon monoxide, when the temperature is raised too high. Moreover, arsenious oxide, sodium arsenite, or arsenic acid may be used in place of arsenic. When a mixture of equal weights of sodium formate and normal sodium ortho-arsenite is heated to temperatures not exceeding 400°, a gaseous mixture of hydrogen arsenide and hydrogen is obtained containing not more than 2—3% of the latter gas.

One great advantage of this reaction is that sulphur compounds and other inorganic and organic compounds of arsenic, for example, solid hydrogen arsenide, Schweinfurt green, arsenic trisulphide, arsenic-containing magenta, etc., all give arsenic trihydride when heated with

sodium formate, or with a mixture of sodium formate and sodium hydroxide. Marsb's test may thus be carried out without it being necessary to transform the arsenic compound into one of its oxygen derivatives. Organic compounds are best destroyed by oxidation with nitric and sulphuric acids, and the dry residue, which may still contain carbon, beated directly with the formate mixture. In some cases, it is an advantage to transform the arsenic acid produced by the oxidation into arsenic sulphide before further treatment. This is best done by means of pure hydrogen sulphide prepared by heating ten parts of the formate-hydroxide mixture with three parts of flowers of sulphur to 400° .

Urine which is to be tested for arsenic is made strongly alkaline and evaporated to dryness, the residue then being treated as above. Acids are first neutralised, and then evaporated, etc. Aniline dyes and textiles dyed with colours containing arsenic can be treated directly with the formate-hydroxide mixture, since organic matter does not affect the reaction, but it is better first to isolate the arsenic as chloride by distillation, and then transform it into the sulphide, or else to destroy the organic matter by fusion with sodium nitrate.

By the above methods it is possible to detect 0.001 mg. of arsenic.

A mixture of antimony oxide and sodium formate gives no trace of hydrogen antimonide when beated to 400° , metallic antimony alone being formed. When, however, sodium antimonite is used instead of antimony oxide, and the mixture rapidly heated to 800° , small quantities of the hydride of antimony are formed. This compound is also produced to a slight extent when metallic antimony is used and the mixture heated to a bright red heat. Antimony tri- and pentasulphides simply give rise to metallic antimony and hydrogen sulphide at 400° . Thus arsenic may be separated from antimony in their compounds by heating with the formate-hydroxide mixture to 400° , the antimony remaining behind in the metallic form. At 800° , however, some antimony also volatilises as the hydride. T. S. P.

Percarbonates. ERNST H. RIESENFELD (*Ber.*, 1910, 43, 2594—2595).—Polemical. A reply to Tanatar (compare this vol., ii, 33, 203, 290, 774). T. S. P.

Silicon Monosulphide. LIVIO CAMBI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 294—300).—When silicon (in the form of ferro-silicon) and sulphur are heated together in an electric arc furnace, a vigorous reaction takes place, and a grey mass results, from which, by sublimation in an electric furnace, silicon monosulphide may be obtained. The compound sublimes at 940 — 980° at 20 — 30 mm., and it occurs in two forms, namely, a black solid which may assume a vitreous character, and a yellow powder. On resublimation of either form, both are produced, the yellow one being deposited in the colder parts of the tube employed. Analysis of either product leads to the formula SiS , and the substance does not appear to be a mixture. The black modification has D_4^{25} 1.853. With alkalis, the compound reacts according to the equation $\text{SiS} + 2\text{KOH} = \text{SiO}_2 + \text{K}_2\text{S} + \text{H}_2$. The black sulphide dissolves in water with evolution of hydrogen sulphide and

formation of soluble silica, and of a finely-divided orange substance, which appears to be related to the oxygenated silicon hydrides of Wöhler (*Annalen*, 1863, 127, 257). It decomposes slowly in water, more rapidly in alkalis, with evolution of hydrogen and formation of silica. It dissolves in hydrofluoric acid, hydrogen being evolved, but it is insoluble in other acids. The yellow sulphide is also hydrolysed with evolution of hydrogen sulphide, but instead of soluble silica and the compound just described, a white, insoluble substance is formed, which yields hydrogen when treated with alkalis.

R. V. S.

The Equilibrium Diagram of the Silver-Cadmium Alloys. GIUSEPPE BRUNI and E. QUERCIGH (*Zeitsch. anorg. Chem.*, 1910, 68, 198—206).—Silver and cadmium are melted together in an atmosphere of nitrogen. The diagram obtained is simpler than that of Rose (Abstr., 1905, ii, 86), although agreeing with it in the form of the liquidus. From 0 to 80 atomic % of cadmium, the alloys form a continuous series of solid solutions. The crystallisation intervals increase from 0 to 40 atomic % Cd, diminish to zero at 50%, increase to 60%, and again reach zero at 80% Cd. This indicates the existence of two compounds, AgCd and AgCd₂, both of which form solid solutions. This part of the curve resembles that of the magnesium-cadmium alloys (Grube, Abstr., 1906, ii, 355). The compound AgCd undergoes a transformation at 433°.

From 80 atomic % Cd to 97%, crystals of AgCd₂ separate, and from this point onwards solid solutions are formed. There is no eutectic point, the freezing point of cadmium being raised by the addition of silver, even in minute proportion.

G. H. D.

Peptisation of Silver Bromide. RAPHAEL E. LIESEGANG (*Zeitsch. Photochem.*, 1910, 9, 60—64).—A theoretical paper in which the author discusses the nature of the changes involved in the granulation and peptisation of the silver haloids.

H. M. D.

Silver Nitrate Formed by the Action of Nitric Acid on Silver Sulphide. HIPPOLYTE GRUENER (*J. Amer. Chem. Soc.*, 1910, 32, 1030—1032).—Boiling nitric acid of concentration above 5% dissolves silver sulphide rapidly, forming silver sulphate and nitrate. Acid stronger than 94%, however, forms only the sulphate. The maximum amount of nitrate (95%) is obtained by the use of 15—20% acid, greater dilution than this resulting in a smaller percentage. The production of the nitrate is diminished by boiling the acid or prolonging its time of action.

W. O. W.

Action of Potassium Hydroxide on Normal Calcium Phosphate. WILLIAM OECHSNER DE CONINCK (*Bull. Acad. roy. Belg.*, 1910, 662—664).—Normal calcium phosphate is not acted on when heated with a large excess of potassium hydroxide at 96—97° for fifty hours.

T. S. P.

The Binary Systems of Calcium Metasilicate with Calcium Chloride and Calcium Fluoride. B. KARANDÉEFF (*Zeitsch. anorg. Chem.*, 1910, 68, 188—197).—Mixtures of calcium carbonate, silica, and calcium fluoride are melted in a carbon tube and subjected to thermal analysis, the porcelain tube of the thermo-couple being protected with a layer of tar and graphite. Calcium metasilicate and calcium fluoride form a simple eutectiferous series, with a eutectic point at 48 molecular % CaF_2 and 1130° . The conversion of pseudowollastonite into wollastonite on cooling may be followed microscopically, but does not produce any thermal effect.

The eutectic point in mixtures of calcium metasilicate and calcium chloride lies close to the calcium chloride point, and 8° below it. Solid solutions may be formed up to 10 molecular % CaCl_2 . There is no evidence of the formation of additive compounds.

C. H. D.

Metallic Strontium. BEN L. GLASCOCK (*J. Amer. Chem. Soc.*, 1910, 32, 1222—1230).—A study has been made of the conditions necessary for the preparation of strontium by the electrolysis of its fused chloride. A quantity of the metal was prepared in the following manner. A hemispherical, cast-iron vessel of 25 cm. diameter was used as a container, and a carbon anode 8 cm. \times 8 cm. was employed. With pure strontium chloride as electrolyte, and a current of 125 amperes and 40 volts for seven hours, 76 grams of strontium were obtained, giving a current efficiency of 5.3%. The metal thus obtained had a purity of 97—98.5%, D 2.55, and specific heat 0.0742.

Strontium is a very light, soft metal, which has a silvery lustre when freshly cut, but rapidly becomes yellow and afterwards coated with a white layer of oxide. It reacts with water, methyl, and ethyl alcohols, ethyl acetoacetate and malonate, and aniline with evolution of hydrogen, and also reacts slowly with boiling ethyl iodide. The metal is without action on silicon tetrachloride. It dissolves readily in liquid ammonia, forming a deep blue solution from which a dark blue precipitate separates. It burns in an atmosphere of carbon dioxide and illuminating gas as energetically as in air, but not so violently as calcium does under similar conditions. When hydrogen and nitrogen are passed over the heated metal, the hydride and nitride are formed. An alloy of strontium and iron has been prepared and is described.

E. G.

The Ternary Alloys of Magnesium, Zinc, and Cadmium. I. GIUSEPPE BRUNI, G. SANDONNINI, and E. QUERCIGH (*Zeitsch. anorg. Chem.*, 1910, 68, 73—90).—Magnesium and zinc form a single compound, MgZn_2 , and no solid solutions. On the other hand, zinc and cadmium form a simple eutectiferous series, whilst magnesium and cadmium form a compound, MgCd , which forms a continuous series of solid solutions with both components. It is found that the system MgZn_2 -Cd behaves like a binary system, and the present investigation includes the alloys of the ternary group MgZn_2 -Cd-Zn, leaving the remainder for a second part.

In the zinc-cadmium series, the eutectic point is at 262° and 73.5 atomic % Cd, and cadmium holds about 3 atomic % Zn in solid

solution. The eutectic point between Zn and $MgZn_2$ lies at 363° and 75 atomic % Mg. The eutectic point $Cd-MgZn_2$ lies at 280° and 80.05 atomic % Cd.

The ternary series examined is therefore of a simple type, having three binary eutectic lines and a ternary eutectic point, the last lying at 250° and 73 atomic % Cd, 25% Zn, and 2% Mg.

The total number of alloys examined in this section of the system is 103.

C. H. D.

Chemical Analyses of Minoan Metals from the Excavations of Crete. ANGELO MOSCO (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 225-228).—Of six samples of lead of Minoan origin only one contained tin (1.460%). It is suggested that the absence of tin objects in the Minoan remains is to be ascribed to the action of the "tin pest." A piece of gold was found to be alloyed with 20% of silver, this alloy being the so-called electron. A piece of silver was found to contain 20% of copper. The two pieces of electron and the piece of silver analysed belong to the third Middle Minoan Period (Evans' classification). A sphere of mineral examined was found to be an emery of the composition:

| Al_2O_3 . | Fe_2O_3 . | CaO. | MgO. | SiO_2 . | Total. |
|-------------|-------------|------|------|-----------|--------|
| 55.40 | 38.60 | 1.50 | 0.54 | 3.70 | 99.74 |

R. V. S.

Antique Glass Mirror. FRANZ W. DAFERT and R. MIKLAUZ (*Monatsh.*, 1910, 31, 781-784).—Chemical investigation of an antique glass mirror found in a large Roman grave-yard in the Wiener Strasse in Leibach shows that it was made by pressing lead foil on to the glass, some kind of balsam being used as an adhesive. In the course of centuries the balsam has resinified and entered into combination with the lead, the lead thereby being converted for the most part into red lead. The lead forming the frame and hinder part of the mirror was changed on the surface into the basic carbonate.

T. S. P.

The Influence of Light on White Lead Blackened by Hydrogen Sulphide. ERNST TÄUFER (*Chem. Zeit.*, 1910, 34, 1126).—Contrary to the results of Sacher (this vol., ii, 712), the author finds that lead sulphide in white lead paints is bleached by the action of light, even in the absence of oxygen. The action is attributed to the peroxides of the drying oils in the paints. A blackened surface of white lead, coated in places with poppy-seed oil, is bleached by light only in the parts coated with oil. Freshly painted surfaces are even bleached in the absence of light, although more slowly.

C. H. D.

Crystallisation of Fused Lead Silicates. SIEGFRIED HILPERT and RICHARD NACKEN (*Ber.*, 1910, 43, 2565-2573. Compare Abstr., 1909, ii, 890).—The authors describe various apparatus by means of which they have taken the cooling curves of fused mixtures of lead oxide and silica, the fused mass being vigorously stirred during the cooling, and have measured the velocity of crystallisation and the crystallisation power (number of nuclei formed) of such fusions at

different temperatures. The results obtained are combined in a freezing-point diagram for mixtures varying in composition from lead monoxide to lead metasilicate. At first sight the curve seems to comprise two eutectics and one maximum, the latter corresponding with lead orthosilicate, m. p. 740° . The eutectics, however, correspond with the compositions $3\text{PbO}, 2\text{SiO}_2$ and $3\text{PbO}, \text{SiO}_2$, and further careful experiments (cooling curves, measurements of velocity of crystallisation, and microscopic examination of thin sections) with mixtures of these compositions show that the first supposed eutectic really consists of two eutectics close together, with a small maximum in between, corresponding with the compound $3\text{PbO}, 2\text{SiO}_2$, m. p. about 690° . The evidence for the second compound, $3\text{PbO}, \text{SiO}_2$, is not so satisfactory, but the examination of thin sections points to its existence.

T. S. P.

Ternary Alloys of Copper, Antimony, and Bismuth. NICOLA PARRAVANO and E. VIVIANI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 197—201, 243—247. Compare this vol., ii, 779, 852).—The first paper contains the experimental results obtained for the ternary systems Cu_3Sb — Sb — Bi , and the diagram of the system constructed with their aid.

In the second this diagram is discussed. Microscopic examination of the alloys has confirmed the results obtained by thermal method, and photomicrographs of some of the typical appearances observed are reproduced in this paper.

R. V. S.

Compounds of Nitric Oxide with Cupric Salts. WILHELM MANCHOT (*Annalen*, 1910, 375, 308—315. Compare Kohlshütter, *Abstr.*, 1904, ii, 734; Manchot, this vol., ii, 137). It has long been known that a solution of copper sulphate in concentrated sulphuric acid develops a violet or bluish-violet coloration with nitric oxide. The author shows that the coloration is due to the formation of an easily dissociable compound of 1 mol. each of copper sulphate and of nitric oxide. Its formation is influenced by the concentration of the water and of the copper salt present. No coloration or absorption of nitric oxide can be detected when sulphuric acid containing less than 70.8% of H_2SO_4 is used, whatever the concentration of the copper sulphate. At 0° and 752 mm., solutions containing 0.0053 to 0.0265 mol. of CuSO_4 per litre of 97.6% sulphuric acid absorb exactly 1 mol. of nitric oxide per 1 atom of copper; with greater concentrations of copper sulphate the amount of nitric oxide absorbed is less. A solution containing about 0.0175 mol. of CuSO_4 absorbs only 1 mol. of nitric oxide per 1 atom of copper when the pressure of the nitric oxide is increased from 322 mm. to 1303 mm.

Similar results are recorded for alcoholic solutions of hydrated cupric chloride. The dark violet compound is even more sensitive than the preceding to the decomposing action of water, for even in absolute alcohol solutions containing 0.005 to 0.1352 mol. of CuCl_2 per litre absorb only 17 to 18 litres of nitric oxide (at 0° and 750—753 mm.) per 1 atom of copper.

When dry hydrogen chloride is led into liquid nitric oxide cooled by liquid air, or when nitric oxide is passed into liquid hydrogen chloride, a dark red liquid is formed, which rapidly solidifies to a dark red, crystalline mass; the substance decomposes, however, even at the temperature of a mixture of solid carbon dioxide and acetone.

C. S.

Atomic Weight of Mercury. II. C. W. EASLEY (*J. Amer. Chem. Soc.*, 1910, 32, 1117—1126).—In an earlier paper (Abstr., 1909, ii, 1013), the atomic weight of mercury was determined by a study of the ratio $\text{HgCl}_2 : 2\text{AgCl}$. In order to confirm the value thus obtained, estimations were made of the mercury in mercuric chloride by precipitating mercuric oxide with sodium hydroxide and reducing it by means of hydrogen peroxide. Although the results of these experiments agreed closely with those obtained by the former method, the difficulty of collecting the mercury completely rendered the process untrustworthy.

Determinations have now been made of the ratio $\text{HgCl}_2 : \text{Hg}$ by the electrolysis of a solution of mercuric chloride. A special method was devised in which the metal was deposited in globular form by means of a mercury cathode, and, without being removed, was washed by decantation, freed from water by means of acetone, and afterwards weighed. The results of five preliminary experiments and of six final experiments each gave a mean value for the atomic weight of mercury, 200.63 ($\text{Cl} = 35.46$), whilst the value obtained in the earlier paper (*loc. cit.*) from the ratio $\text{HgCl}_2 : 2\text{AgCl}$ was 200.62.

E. G.

Ultra-microscopic Observations of the Hydrolysis of Mercuric Chloride. HERMANN W. FISCHER and E. BRIEGER (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 196—197).—An aqueous solution of mercuric chloride has been found to contain a number of ultra-microscopic particles. These are attributed to the formation of a colloidal substance as a result of hydrolytic decomposition. The colloidal product ages with time, and becomes less soluble; this leads to further hydrolytic decomposition and to an increase in the number of ultra-microscopic particles. Rise of temperature has the same effect, and this observation supports the view that the presence of sub-microns is due to hydrolysis. The protective influence of sodium chloride on a solution of mercuric chloride is attributed to the diminution of the hydrolysis in consequence of the formation of the complex salt Na_2HgCl_4 .

H. M. D.

Lutetium and Neoytterbium or Cassiopeium and Aldebaranium. GEORGES URRAIN (*Zeitsch. anorg. Chem.*, 1910, 68, 236—242).—Claim for priority against Welsbach (Abstr., 1908 ii, 591; compare Abstr., 1908, ii, 283, 849).

C. H. D.

The Preparation of Manganio Fluorides and the Titration of Manganese by Volhard's Method in Presence of Fluorides. ERICH MÜLLER and PAUL KORPE (*Zeitsch. anorg. Chem.*, 1910, 68, 160—164).—Manganic fluoride has been prepared previously from

manganous oxide and hydrofluoric acid. A fluoride of tervalent manganese is readily obtained by the action of permanganates on a manganous salt in presence of hydrofluoric acid, the reaction being: $\text{MnO}_4^- + 4\text{Mn}^{++} + 8\text{H}^+ = 5\text{Mn}^{+++} + 4\text{H}_2\text{O}$. The difference between the reactions in presence of hydrofluoric and sulphuric acids is due to the conversion of Mn^{+++} into a complex fluoride ion in the former case.

By mixing, in the order given, a solution of 8.9 grams of manganous sulphate in 30 c.c. of water, 8 c.c. of 40% hydrofluoric acid, a solution of 1.58 grams of potassium permanganate in 25 c.c. of water, and one of 5.8 grams of potassium fluoride in 20 c.c., in a platinum basin, a salt is obtained which, after washing with hydrofluoric acid and alcohol and drying in a desiccator, has the composition $2\text{KF}, \text{MnF}_2, \text{H}_2\text{O}$.

Manganese dioxide, which is insoluble in hydrofluoric acid, dissolves if a manganous salt is also present. Manganic fluoride, free from potassium, may be obtained by electrolysis of a neutral solution of a manganous salt and dissolving the oxide precipitated at the anode in hydrofluoric acid.

The difficulty of observing the end-point in presence of the pink manganic salt makes it impossible to obtain accurate results on titrating manganese with permanganate in presence of hydrofluoric acid. The reaction appears, however, to be nearly complete in a warm solution. The presence of fluorides causes a large error in the titration of manganese by Volhard's method, but not in the titration of ferrous salts.

G. H. D.

Electrolytic Conversion of Manganates into Permanganates. KURT BRAND and J. E. RAMSBOTTOM (*J. pr. Chem.*, 1910, [ii], 82, 336—396).—The authors have been forestalled by Askenasy and Klonowsky (this vol., ii, 413) in the publication of their results. The manganate melt for the electrolytic production of potassium permanganate is made by heating manganese dioxide, potassium hydroxide, and a little water at a dark red heat, oxygen being supplied by the atmosphere and not by potassium nitrate or chlorate, since the addition of the latter results in the formation of potassium nitrite or chloride, the presence of either of which during the electrolysis is disadvantageous.

The apparatus consists of a slender glass vessel containing an earthenware vessel in which are the anode of nickel gauze and the anodic liquor, consisting of a solution containing 4% of potassium manganate and 14% of potassium hydroxide; the cathode is also made of nickel, and the surrounding solution is 2.2% potassium hydroxide. The results of the experiments show that the yield of potassium permanganate is appreciably increased by stirring thoroughly the anodic solution, and decreases with increase of the current density at the anode, the highest practicable value being 0.0125 ampere per sq. cm. with a nickel anode, and 0.005 with an iron anode.

The solubility of potassium permanganate in aqueous potassium hydroxide of varying strength has been determined, and it is shown

that the potassium permanganate remaining dissolved in the anodic liquor can be isolated, either by evaporating the solution carefully, protected from dust particles, etc., or by continually adding the solid manganate melt to the anodic solution during the electrolysis, whereby the concentration of the potassium hydroxide becomes ultimately so great that the potassium permanganate is almost entirely precipitated.

C. S.

The System Iron-Nickel. RUDOLF RUER and EMIL SCHÜZ (*Metallurgie*, 1920, 7, 415—420).—The freezing-point curve of the system iron-nickel, determined from quantities of 150 grams, is continuous, with a shallow minimum, and the liquidus and solidus curves practically coincide throughout. Determinations of the temperatures of magnetic transformation yield results in general agreement with those of Guillaume and Osmond, but the boundary between the reversible and irreversible alloys is now placed at 29% of nickel. The maximum of the reversible transformation curve at 618° and the minimum of the freezing-point curve at 1435° both lie near to 70% of nickel, pointing to the existence of a compound FeNi_2 .

The electrical conductivity of rods cast in narrow magnesia cylinders and annealed by heating to 900° and cooling slowly, shows a minimum at 35% Ni, and the compound FeNi_2 is not indicated on the curve.

C. H. D.

Goldschmidt's Ferroboron and Manganese-Boron, and the Residue Obtained on Heating Ferroboron in Hydrogen Sulphide. JOSEF HOFFMANN (*Chem. Zeit.*, 1910, 34, 1045—1046. Compare this vol., ii, 508).—Goldschmidt's borides behave towards reagents as heterogeneous substances, and this view is confirmed by microscopical examination, which shows distinct crystallites in a homogeneous ground mass. Detailed descriptions of some of the crystals are given.

The residue obtained when hydrogen sulphide acts on ferroboron contains borides which are resistant to acids, and also boron sulphide and a sulphur compound which is not ferrous sulphide, but probably a ferrous thioboride.

C. H. D.

Complex Compounds of Cobalt with Chloric and Perchloric Acids. ROBERTO SALVADORI (*Gazzetta*, 1910, 40, ii, 9—18).—A number of cobaltiammine chlorates and perchlorates have been examined. They are all explosive, the chlorates by percussion or on ignition, the perchlorates by percussion or detonation. The perchlorates are very stable at the ordinary temperature, whilst the chlorates decompose slowly, the luteo-derivatives being more stable than the roseo- or purpureo-compounds.

For the analysis, the chlorates are reduced by means of ferrous sulphate in ammoniacal solution, and the perchlorates by fusion with sodium carbonate in a platinum crucible placed in an outer crucible also containing sodium carbonate. Ammonia is estimated by distillation with sodium hydroxide, and cobalt by electrolytic reduction in presence of ammonium oxalate. The metallic deposit contains carbon,

and it is necessary to dissolve it in sulphuric acid, to filter, and to re-deposit the cobalt electrolytically.

Luteo-cobaltiammine chlorate, $\text{Co}(\text{NH}_3)_6(\text{ClO}_3)_3 \cdot \text{H}_2\text{O}$, prepared by passing oxygen through a 5% solution of cobalt chloride in an excess of ammonia at 50° , adding chloric acid, and evaporating, forms yellow crystals, and explodes at 120° if rapidly heated. It may be obtained in an anhydrous form from luteo-cobaltiammine chloride and silver chlorate by cooling the filtrate in a freezing mixture. It then forms yellow needles, soluble in water to the extent of 7.87% at 18° , much more at higher temperatures.

Cobalthydrazine perchlorate, $\text{Co}(\text{N}_2\text{H}_4)_2(\text{ClO}_4)_2$, obtained by adding hydrazine hydrate to luteo-cobaltiammine chloride, forms yellow crystals, which are highly explosive. If carbon dioxide is passed into the solution containing hydrazine hydrate, cobalthydrazine carbonate and hydrazine hydrochloride are formed, and nitrogen is evolved, the reaction probably proceeding as follows:

Roseo-cobaltiammine chlorate, obtained from the mother liquor of the luteo-salt, or from silver chlorate and roseo-cobaltiammine chloride, is a pink, very soluble powder, the solubility in water at 18° being 105.8%. The *purpureo*-salt, also obtained by double decomposition, forms large, garnet-red tetrahedra.

Cobalt perchlorate, $\text{Co}(\text{ClO}_4)_2 \cdot 6\text{H}_2\text{O}$, prepared from cobalt carbonate and perchloric acid, and crystallised slowly, forms prisms 4 cm. long, loses water at 100° to form a violet, hygroscopic powder, and explodes by percussion. When rapidly heated, it deflagrates without exploding. When ammonia and ammonium perchlorate are added to its solution, a red powder having the composition $\text{Co}(\text{ClO}_4)_2 \cdot 6\text{NH}_3$ is precipitated, ammonia directly replacing water. Boiling water decomposes it according to the equation:

Other metallic perchlorates behave in a similar manner.

Luteo-cobaltiammine perchlorate, $\text{Co}(\text{NH}_3)_6(\text{ClO}_4)_3 \cdot \text{H}_2\text{O}$, is soluble in water to the extent of 0.967% at 18° (compare Alvisi, Abstr., 1902, ii, 24). *Roseo-cobaltiammine perchlorate*,

and the *purpureo*-salt dissolve in water at 18° to the extent of 7.4% and 11% respectively. C. H. D.

Compounds of Chromium. VIII. Triamminechromium Salts. ALFRED WERNER (*Ber.*, 1910, 43, 2286—2295).—The starting point in the preparation of triamminechromium salts is triamminechromium tetroxide, for which a new method of preparation is given. To a strongly cooled solution of 30 grams of chromic acid in 300 c.c. of water are added 300 c.c. of pyridine. After remaining for half an hour in a freezing mixture, 750 c.c. of 3% hydrogen peroxide are added. The precipitated pyridine perchromate is collected, washed, and added to 90 c.c. of well-cooled 25% ammonia. The precipitated triamminechromium tetroxide is collected after ten minutes and washed with water, alcohol, and ether.

Trichlorotriamminechromium, $(\text{NH}_3)_3\text{CrCl}_3$, results when triamminechromium tetroxide is added to cold concentrated hydrochloric acid. A grey to bluish-grey precipitate is formed, and the filtrate from this deposits the trichlorotriamminechromium on keeping for two days. The crystals are dark blue with a greenish tinge. It is almost insoluble in water, in which properties it resembles trichlorotriamminecobalt. It dissolves in hot water, giving a blue solution, from which the dichloroaquatriamminechromium salts (Abstr., 1906, ii, 760) are precipitated by appropriate reagents. The grey to bluish-grey precipitate mentioned above is probably a mixture of dichloroaquatriamminechromium chloride and trichlorotriamminechromium.

Triaquatriamminechromium chloride, YCl_3 , where $\text{Y} = \left[\text{Cr} \begin{smallmatrix} (\text{NH}_3)_3 \\ (\text{OH})_3 \end{smallmatrix} \right]$, is obtained as follows: A mixture of 1 gram of dichloroaquatriamminechromium chloride with 8 c.c. of water is covered with 5 c.c. of pyridine. The resulting solution is filtered, and the hydroxiodide precipitated by the addition of solid potassium iodide. The chloride is then obtained by triturating the hydroxiodide with concentrated hydrochloric acid. After purification by solution in water and precipitation with hydrogen chloride, it forms brownish-red, hygroscopic crystals. It was also prepared by dissolving triamminechromium tetroxide in dilute hydrochloric acid (1:4) and saturating the cooled solution with hydrogen chloride. The *chloride-nitrate*, YCl_2NO_3 , is precipitated when concentrated nitric acid is added to a cold concentrated solution of the chloride. When nitric acid is replaced by perchloric acid, pale red plates of the *perchlorate*, $\text{Y}(\text{ClO}_4)_3$, are obtained.

Dibromoaquatriamminechromium salts, YX , where $\text{Y} = \left[\text{Br}_2\text{Cr} \begin{smallmatrix} \text{OH}_2 \\ (\text{NH}_3)_2 \end{smallmatrix} \right]$. To prepare the *bromide*, YBr , triamminechromium tetroxide is dissolved in cooled hydrobromic acid (D 1.49), whereby bromine is evolved, and concentrated sulphuric acid added to the well-cooled solution. Intense green crystals are obtained, soluble in water to a green solution, which rapidly turns bluish-red. The *iodide*, YI , *thiocyanate*, YSCN , *nitrate*, YNO_3 , and *sulphate*, Y_2SO_4 , all form green crystals, and are prepared from a fresh solution of the bromide by precipitation with potassium iodide, potassium thiocyanate, nitric and sulphuric acids respectively. The green colour of these salts corresponds with that of the dichloro- and dibromo-diethylenediaminechromium salts. The dichloroaquatriamminechromium salts are, however, blue. This difference in colour is not due to a difference in constitution, since when the green dibromo-bromide is converted into triaquatriamminechromium nitrate, $\left[\text{Cr} \begin{smallmatrix} (\text{OH})_3 \\ (\text{NH}_3)_3 \end{smallmatrix} \right](\text{NO}_3)_3$, by means of silver nitrate, and the dichloroaquatriamminechromium nitrate prepared from this by means of hydrogen chloride, the usual blue salt is obtained. Both the green and the blue salts are therefore praseo-salts.

Bromodiaquatriamminechromium salts, YX_2 , where $\text{Y} = \left[\text{BrCr} \begin{smallmatrix} (\text{OH})_2 \\ (\text{NH}_3)_2 \end{smallmatrix} \right]$. Five grams of triamminechromium tetroxide are dissolved in 50 grams

of well-cooled hydrobromic acid (D 1.49). The solution is then boiled until bromine ceases to be evolved, cooled, and 80 c.c. of concentrated sulphuric acid added, whereby a brownish-red, crystalline deposit forms. If this is dissolved in water, the solution rapidly filtered, and the filtrate treated with concentrated hydrobromic acid, reddish-violet crystals of the *bromide*, YBr_3 , are obtained. With concentrated hydrochloric acid, the solution of the bromide gives reddish-violet crystals of the *chloride*, YCl_3 , from which salt the *sulphate*, YSO_4 , may be obtained as violet crystals. The transformation of the chloride into the sulphate proves that the bromine is in the complex.

Hitherto, it has not been possible to isolate the tribromotriammine-chromium, only the following three hydrates of the bromo-series being known, namely: $\left[\text{Br}_2\text{Cr}\left(\text{NH}_3\right)_3\right]\text{Br}$, $\left[\text{BrCr}\left(\text{OH}_2\right)_2\left(\text{NH}_3\right)_3\right]\text{Br}_2$, and $\left[\text{Cr}\left(\text{OH}_2\right)_3\left(\text{NH}_3\right)_3\right]\text{Br}_3$.

T. S. P.

The Behaviour of Iron towards Solutions of Stannous Salts. ALFRED THIEL and K. KELLER (*Zeitsch. anorg. Chem.*, 1910, 68, 220—235).—The fact that when iron is added to a solution of the chlorides of tin and antimony, only antimony is precipitated, is in contradiction to the positions of iron and tin in the electrochemical series. It is now shown that tin is actually precipitated, but only in very minute quantity, forming a very thin protecting layer of a tin-iron alloy on the surface of the iron.

Iron dissolves much less rapidly in an acid if a tin salt is present. Measurements of electrolytic potential show that in pure acid tin is always less noble than iron, the difference being greater in stronger acids. In acid containing a stannous salt the potential of iron varies, and finally assumes a value equal, or near, to that of tin, according to the conditions. The deposition of tin on iron is recognisable by analysis, if iron having a relatively large surface, such as turnings, is taken for the experiment.

If iron is introduced into a vessel containing a concentrated electrolyte, containing tin in the lower part, and a more dilute electrolyte free from tin in the upper part, the iron becomes covered with crystals of tin where it dips into the concentrated electrolyte, but remains free from tin if immersed completely in either the concentrated or the dilute solution.

O. H. D.

Atomic Weight of Tantalum. CLARENCE W. BALKE (*J. Amer. Chem. Soc.*, 1910, 32, 1127—1133).—Owing to the uncertainty existing with regard to the value of the atomic weight of tantalum, determinations have been made of the ratio $2\text{TaCl}_5:\text{Ta}_2\text{O}_5$, the chloride being converted into the oxide by methods similar to those used in the determination of the atomic weight of columbium by Balke and Smith (*Abstr.*, 1908, ii, 1043).

Tantalum chloride was prepared by heating the oxide in a current of chlorine and vapour of sulphur chloride. The chloride was converted into the oxide in quartz bulbs. The bulbs containing the chloride

were placed in a vacuum desiccator with water, and the air was pumped out. The chloride gradually underwent hydrolysis; small quantities of water and concentrated nitric acid were then introduced into the bulb, and the mass was evaporated to dryness. The addition of water and nitric acid and the subsequent evaporation were twice repeated, and the dry mass was finally ignited until no further loss of weight occurred. The mean of eight experiments with three samples of the chloride gave a value for the atomic weight 181.52 ($\text{Cl} = 35.46$), whilst the value given in the international table of atomic weights is 181.0.

Tantalum chloride has D 3.68 at 27° . Specimens of the oxide prepared from the chloride had D varying from 7.91 to 8.62.

E. G.

Easy Method for Preparing Colloidal Gold. WILLIAM OECHSNER DE CONINCK (*Bull. Acad. roy. Belg.*, 1910, 664—665).—A dilute solution of gold chloride containing a little starch is heated for a short time and then filtered. The filtrate is at first colourless, but gradually becomes deep violet in colour. The starch remaining on the filter paper is coloured violet, and after a few days presents a metallic reflecting surface. On exposing the violet filtrate to diffused light for some days, the gold is slowly deposited.

If the original solution of gold chloride and starch is gently heated for some minutes, the filtrate, which is opalescent, will reduce Fehling's solution.

Mineralogical Chemistry.

A Method for Isolating Native Iron from Basalt without Destroying its Form. MAX SEEBACH (*Centr. Min.*, 1910, 641—643).

—Native iron occurs in the basalt of Bühl, near Weimar, in the form of a fine network. The basalt may be removed without destroying the form of the iron by heating with Plattner's flux (10 parts sodium carbonate, 13 parts potassium carbonate, 5 parts borax glass, and 5 parts dry starch) in a graphite crucible. In order to prevent the formation of a thin layer of oxide on the iron, charcoal may be mixed with the flux, and the whole covered with a layer of sodium chloride. A piece of basalt 1 c.c. in size is destroyed in one and a-half hours. The last traces of rock enclosed in the meshes of the iron are removed by fusion with boron trioxide. When it is only required to isolate the iron, without preserving its form, it is best to crush the basalt and fuse with boron trioxide.

C. H. D.

Diffusion of Crude Petroleum through Fuller's Earth. J. ELLIOTT GILPIN and OSCAR E. BRANSBY (*Amer. Chem. J.*, 1910, 44, 251—303).—Gilpin and Cram (*Abstr.*, 1909, i, 1) have shown that when petroleum is allowed to diffuse upwards through tubes packed

with fuller's earth, fractionation takes place, and the fractions rising to the top of the tubes are of lower sp. gr. than those at the bottom. The paraffin hydrocarbons collect in the upper parts of the tubes, and the unsaturated hydrocarbons in the lower parts.

A study has now been made of the behaviour of crude Illinois petroleum when treated in this way. Gilpin and Cram's results have been confirmed, and it has been found that the amount of the sulphur compounds, like that of the unsaturated hydrocarbons, increases gradually from the lightest oil at the top to the heavier oils at the bottom of the tube. When a solution of benzene in petroleum is allowed to diffuse through fuller's earth, the benzene, like the olefines and sulphur compounds, tends to accumulate in the lower part of the tube.

When fuller's earth, which has been used for such diffusion experiments and afterwards treated with water in order to remove as much oil as possible, is dried and extracted with ether, oils of high specific gravity and viscosity are obtained containing considerable quantities of unsaturated hydrocarbons and sulphur compounds. It is therefore evident that fuller's earth exercises a selective action on the petroleum.

A discussion is given of the causes of the differences between the various oils of the United States. Pennsylvania petroleum differs from those of Ohio, Texas, and California in containing a much larger proportion of paraffin hydrocarbons and a much smaller proportion of benzene, unsaturated hydrocarbons, and compounds of sulphur and of nitrogen. In view of the results of the present investigation, it is suggested that this difference may be explained by assuming that the Pennsylvania petroleum has diffused upwards through porous media, such as shales, limestones, and sandstones, and thus undergone fractionation, resulting in the removal of the unsaturated and aromatic hydrocarbons and the sulphur compounds. It is probable that the nitrogen compounds also behave like the unsaturated hydrocarbons and sulphur compounds, and this question is being studied. E. G.

Grahamite, a Solid Native Bitumen. CLIFFORD RICHARDSON (*J. Amer. Chem. Soc.*, 1910, 32, 1032—1049).—There is a regular gradation in properties and composition between paraffins, asphalt, manjaks, and grahamites, corresponding probably with different stages of metamorphism. The author discusses the relations between these minerals, and suggests that the term "grahamite" should be confined to that type of solid, native bitumen characterised by a schistose or hackly fracture, by its sparing solubility in naphtha, and by a high percentage of residual coke.

A list of occurrences of grahamite in America is given in tabular form, with the physical properties, percentage of bitumen, and ultimate composition of the bitumen. The bitumen from a typical grahamite from West Virginia gave C 86.56, H 8.68, and S 1.75%. The ash of grahamites contains vanadium, that of a specimen from the Inupson Valley containing 11—15% of V_2O_5 (compare Hewett, this vol., ii, 719). Trinidad bitumen should be classed as a grahamite rather than as a manjak. W. O. W.

Mosesite, a New Mercury Mineral from Terlingua, Texas. FREDERICK A. CANFIELD, WILLIAM F. HILLEBRAND, and WALDEMAR T. SCHALLER (*Amer. J. Sci.*, 1910, [iv], 30, 202—208).—The mineral occurs as minute simple octahedra, or spinel-twins, on calcite, and is canary-yellow with an adamantine lustre. It is a mercury-ammonium compound with chlorine (about 5%) and sulphate (about 3.5% SO_4), being thus similar to kleinite (Abstr., 1907, ii, 788), but probably with mercurous, rather than mercuric, sulphate and chloride. In hydrochloric acid it is very slowly changed to calomel, whilst kleinite is completely, although very slowly, dissolved. Heated gradually in a bulb-tube, mosesite first changes colour to black, then to white, and at a higher temperature volatilises, giving sublimates of calomel and mercury. The crystals are optically birefringent, but they become isotropic at 186° ; on cooling they revert very slowly to the birefringent modification. Kleinite shows the same change from the optically birefringent to the isotropic state at a slightly higher temperature.

L. J. S.

The Synthetic Sapphires of Verneuil. ALFRED J. MOSES (*Amer. J. Sci.*, 1910, [iv], 30, 271—274).—The crystallised corundum of a fine sapphire-blue colour prepared artificially by A. Verneuil (this vol., ii, 212) gave, on analyses by M. A. Lamme, Al_2O_3 , 99.83—99.85%; TiO_2 , 0.11—0.13%; Fe_2O_3 , trace; SiO_2 , nil; D 3.977—4.01. Refractive indices (sodium-light), $\omega = 1.7680$, $\epsilon = 1.7594$. The pleochroism is distinct (ω , indigo-blue, ϵ , pale blue). The optical interference-figure varies from uniaxial to slightly biaxial in character, and the optic axis is inclined at about 40° to the axis of the conical mass.

L. J. S.

Lanthanite. GUSTAF LINDSTRÖM (*Jahrb. Min.*, 1910, ii, Ref. 15; from *Geol. För. Förh. Stockholm*, 1910, 32, 206—214).—Lanthanite of D 2.69—2.74, collected from cerite specimens from Bastnäs, Sweden, gave on analysis:

| $(\text{La}, \text{Di})_2\text{O}_3$ | Ce_2O_3 | Y_2O_3 | CO_2 | H_2O | Insoluble. | Total. |
|--------------------------------------|-------------------------|------------------------|---------------|----------------------|------------|--------|
| 28.34 | 25.52 | 0.79 | 21.95 | 23.40 | 0.13 | 100.13 |

This, like the analyses of American lanthanite, agrees with the formula $\text{R}_2\text{O}_{11} \cdot 3\text{CO}_2 \cdot 8\text{H}_2\text{O}$.

Hisinger's analysis of "hydrofluocerite" from Bastnäs has come to be wrongly quoted in the text-books under lanthanite, owing to the incorrect translation of the Swedish "flusspatssyra" as "carbonic acid" in an early abstract in *Edin. J. Sci.*, 1826.

L. J. S.

New Occurrence of Hydrogiobertite. ROGER C. WELLS (*Amer. J. Sci.*, 1910, [iv], 30, 189—190).—The material occurs in considerable amount as a white encrustation on shale in Chiles Valley, Napa Co., California, and has been deposited from the water of springs; the serpentine-rocks occurring in the neighbourhood probably supplied the magnesium. The structure is spherulitic, and the spherules often contain a nucleus of shale; D 2.152. Analyses of material containing

admixed shale gave the following results, agreeing with the hydrogiobertite formula: $2\text{MgO} \cdot \text{CO}_2 \cdot 3\text{H}_2\text{O}$.

| Insoluble. | (Al, Fe) ₂ O ₃ | CaO. | MgO. | CO ₂ | H ₂ O. | Total. |
|------------|--------------------------------------|------|-------|-----------------|-------------------|--------|
| 25.33 | 1.90 | 2.60 | 31.81 | 18.06 | 20.06 | 99.76 |
| 14.93 | 1.06 | 1.84 | 36.40 | 23.71 | 20.81 | 98.75 |

L. J. S.

Analyses of Minerals from Croatia. FR. TUČAN (*Jahrb. Min.*, 1910, ii, Ref. 39—41; from *Glasnik [Berichte] kroat. naturv. Ges., Agram*, 1907, 19).—I. Dolomite from the Fruška mountains; pale green, coarsely granular, from serpentine-rocks. II. Magnesite from the Bušnica stream near Trgove; milk-white, compact with conchoidal fracture, from serpentine-rocks. III. Magnesite from the Bečinski potok stream in the Fruška mountains; similar to the last. IV—VI. Strontianocalcite from Radoboj; fibrous aggregates associated with strontianite. VII. Hydrozincite from Ivanec in the Ivančica mountains; milk-white, reniform aggregates associated with smithsonite. VIII—X. Muscovite from the pegmatites at various localities in the Krndija mountains.

L. J. S.

Chalybite from Croatia. FR. TUČAN (*Jahrb. Min.*, 1910, ii, Ref. 12; from *Nastavni vjesnik, Monatsber. kroat. Mittelschulver., Agram*, 1908, 17).—Fourteen analyses are given of chalybite from various localities in Croatia.

L. J. S.

New Occurrence of Plumbojarosite. WILLIAM F. HILLEBRAND and FRED. E. WRIGHT (*Amer. J. Sci.*, 1910, [iv], 30, 191—192. Compare Abstr., 1902, ii, 667).—The mineral was found at American Fork, Utah, as friable lumps consisting of minute, brownish-red, glistening crystals with pyromorphite and calcite. The crystals are rhombohedral, with the basal pinacoid largely developed, and a rhombohedron ($\sigma = 53^\circ 40'$ about); they are optically uniaxial and negative, and strongly dichroic. Analysis gave:

| Fe ₂ O ₃ . | PbO. | K ₂ O. | Na ₂ O. | SO ₂ . | H ₂ O. | CuO. | CaO. | Insol. | Total. |
|----------------------------------|-------|-------------------|--------------------|-------------------|-------------------|------|------|--------|--------|
| 42.87* | 18.46 | 0.15 | 0.52 | 27.67 | 10.14 | 0.10 | 0.06 | 0.40 | 100.37 |

* Including very little P₂O₅ and probably some Al₂O₃.

L. J. S.

Oxalite from Cape d'Arco (Island of Elba). ERNESTO MANASSE (*Atti. R. Accad. Lincei*, 1910, [v], 19, ii, 138—145).—The mineral was found in a vein of oxide and hydroxide of iron and manganese, which also contains pyrites and galena. It forms small, transparent prisms or tablets of an amber-yellow colour, hardness about 2, D 2.28. Analysis leads to the formula $\text{FeC}_2\text{O}_4 \cdot 3\text{H}_2\text{O}$

| FeO. | MgO. | C ₂ O ₄ . | H ₂ O (by difference). |
|-------|-------|---------------------------------|-----------------------------------|
| 40.72 | trace | 40.18 | 19.10 |

An oxalate of similar composition, but only microcrystalline, was prepared from ferrous ammonium sulphate or ferrous chloride, with oxalic acid. The crystallographic examination of the mineral gave $[a:b:c = 0.77297:1:1.10392]$. The crystals are birefractive to an unusual degree.

R. V. S.

Mizzonite from Cape d'Arco (Island of Elba). ERNESTO MANASSE (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 211—215).—The mineral was found in association with quartz in small veins of manganese oxide and hydroxide in a mine which yields iron and manganese. In close proximity occur crystalline schists and calcite of presilurian origin. It has hardness 5—6, and D 2.60. The crystals are prismatic, have a nacreous lustre, and are birefractive. Analysis gave:

| SiO ₂ . | Al ₂ O ₃ . | Fe ₂ O ₃ . | CaO. | MgO. | Na ₂ O. | K ₂ O. | Cl. | Loss at red heat | Total. |
|--------------------|----------------------------------|----------------------------------|-------|-------|--------------------|-------------------|------|------------------|--------|
| 54.40 | 24.44 | trace | 10.19 | trace | 7.59 | 1.69 | 1.53 | 1.43 | 101.27 |

which is in agreement with those required by the amorphous mixture,

The values observed for the indices of refraction and the birefracton are also in accord with this structure.

R. V. S.

Minerals from Ruwenzori. LUIGI COLOMBA (*Jahrb. Min.*, 1910, ii, Ref. 41—42; from "*Il Ruwenzori*" by the *Duca degli Abruzzi*, Milano, 1909, 2, 281—286).—The minerals collected from the amphibolite, granite, and pegmatite are described, and analysis given of the following: I—IV, Epidote, as small, striated needles (I, greyish-green; II, pale green; III, brownish-green; IV, colourless, from Lake of Garda in northern Italy). In analysis III the ratio of

whilst in the others it is 2 : 1 : 2. V, Albite, as small crystal druses in crevices; VI, Microcline, massive; VII, Garnet (pyrope), as bright red, distorted crystals associated with microcline; VIII, Ilmenite, indistinct crystals, associated with albite:

| | SiO ₂ . | Al ₂ O ₃ . | Fe ₂ O ₃ . | FeO. | CaO. | MgO. | K ₂ O. | Na ₂ O. | H ₂ O. | Total. |

| VIII. | 52.73 | 45.83 | nil. | 1.25 | 99.81 |

L. J. S.

A Garnet containing Iron and Chromium from Praborna (St. Marcel). LUIGI COLOMBA (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 146—150).—The mineral occurs in association with hematite, quartz, albite, and titanite, whilst native gold and kammererite are also to be found in the same situation. Analysis yielded the following figures:

| SiO ₂ . | Al ₂ O ₃ . | Fe ₂ O ₃ . | Cr ₂ O ₃ . | CaO. | MgO. | MnO. | FeO. | Total. |
|--------------------|----------------------------------|----------------------------------|----------------------------------|-------|-------|------|------|--------|
| 35.57 | 0.62 | 22.22 | 7.81 | 27.13 | trace | 3.94 | 2.51 | 99.80 |

which correspond, when the small amount of aluminium is neglected, with the typical garnet composition $R_3(R_2)''^{VI}Si_3O_{12}$. From a comparison of the analytical data with those found for various specimens of uvarowite, the author considers it probable that this mineral also belongs to that group. It has D 3.81, and is very strongly birefractive.

R. V. S.

Gageite, a New Mineral from Franklin, New Jersey. ALEXANDER H. PHILLIPS (*Amer. J. Sci.*, 1910, [iv], 30, 283—284).—This is found in very small amount as delicate acicular and hair-like, colourless crystals arranged in radiating bundles, and is associated with zincite, willemite, calcite, and leucopheniceite. When heated, the clear crystals lose water and assume a deep bronze colour. Analysis by R. B. Gage gave:

| SiO ₂ . | MnO. | ZnO. | MgO. | H ₂ O. | Total. |
|--------------------|-------|------|-------|-------------------|---------|
| 24.71. | 50.19 | 8.76 | 11.91 | [4.43] | 100.00. |

Formula: $8RO \cdot 3SiO_2 \cdot 2H_2O$. The mineral appears to be closely related to leucopheniceite (Penfield and Warren, Abstr., 1900, ii, 89), and it is, perhaps, one of the undescribed species mentioned by Penfield and Warren.

L. J. S.

The Chemical Composition of the Stassfurt Salt Clays. E. MARCUS and WILHELM BILTZ (*Zeitsch. anorg. Chem.*, 1910, 68, 91—101).—The portion soluble in water is estimated by boiling with water and washing until no more chlorine passes through. The main analysis is made by Hillebrand's method. Water is estimated by heating with dried sodium carbonate or lead oxide in a current of air. The methods employed are described in detail. In the following analyses, arranged in order of depth, I is a hard salt clay, II a shaly salt clay, III a soft loamy clay, and IV a hard clay immediately in contact with the anhydrite.

Soluble in Water:

| | NaCl. | KCl. | MgCl ₂ . | K ₂ SO ₄ . | CaSO ₄ . | MgSO ₄ . |
|------|-------|------|---------------------|----------------------------------|---------------------|---------------------|
| I. | 0.36 | — | — | 16.94 | 36.11 | 12.08 |
| II. | 0.61 | 0.31 | 0.73 | — | 35.14 | 0.94 |
| III. | 1.09 | 0.40 | 5.41 | 0.33 | 1.19 | — |
| IV. | 0.23 | 0.16 | 1.44 | — | 0.92 | 0.71 |

Insoluble:

| | CaSO ₄ . | CaO. | MgCO ₃ . | MgO. | K ₂ O. | Na ₂ O. | Al ₂ O ₃ . | Fe ₂ O ₃ . | FeO. | Mn ₂ O ₃ . | ZnO. | SiO ₂ . |
|------|---------------------|------|---------------------|-------|-------------------|--------------------|----------------------------------|----------------------------------|------|----------------------------------|-------|--------------------|

| IV. | 0.13 | 0.08 | 3.94 | 0.22 | — | 0.03 | <0.01 | 100.25 | 0.11 |

All contain traces of lithium and chromium, and all but (I) also contain small quantities of boric acid and bromine. The minute quantities of ammonia, nitrates, and copper have been recorded previously (Abstr., 1909, ii, 571, 1011). C. H. D.

The Amount of Thorium in Sedimentary Rocks. II. Arenaceous and Argillaceous Rocks. JOHN JOLY (*Phil. Mag.*, 1910, [vi], 20, 353—357).—Whereas the calcareous rocks show a small, almost negligible, quantity of thorium (compare this vol., ii, 723), the detrital sediments in almost every case contain easily measured amounts, the argillaceous group having almost double the amount in the arenaceous group. For the former 1.3, and for the latter 0.6 ($\times 10^{-5}$ gram per gram), may be taken as average values. Twelve specimens of arenaceous and conglomeritic rocks, mainly sandstones, were examined, and eighteen specimens of argillites, mainly slates. A specimen designated as "Grauwacke, Wipperfurth, Rhénus-Prussia, Middle Devonian" gave the highest result (2.4). The higher thorium content of the slates and shales is attributed to the sorting out by gravity of the large particles of quartz or felspar which are poor in radioactive constituents. F. S.

Physiological Chemistry.

Influence of a Rise of Body Temperature on the Blood Gases. WILHELM CASPARI and ADOLF LOEWY (*Biochem. Zeitsch.*, 1910, 27, 405—417).—At great altitudes (Monte Rosa) a rise of body temperature is very frequent, and symptoms of acidosis occur. The fall in the oxygen tension is compensated for by increased respiration, so that the oxygen in the tissues is but little affected; the elevation of body temperature and the acidosis are favourable factors for the dissociation of oxyhæmoglobin in the tissues. The body is thus able to compensate for the alterations in pressure. The heart is not affected. W. D. H.

The Gases of Cat's Blood. GEORGE A. BUCKMASTER and JOHN A. GARDNER (*J. Physiol.*, 1910, 41, 60—63).—Data of the gases in cat's blood are scanty; the authors used their new form of gas pump. The following are the mean figures of numerous analyses. In the third line the analyses were made with a Töpler-Barcroft pump; here the nitrogen values were between 1.5 and 4%; these have been adjusted to 1.00 to make the figures comparable to those in the first

line. The cats used were killed either by a blow on the head or were anaesthetised with urethane:

| | Total gas. | CO ₂ . | Oxygen. | Nitrogen. |
|----------------------|------------|-------------------|---------|-----------|
| Arterial blood | 39.68 | 25.07 | 13.60 | 1.00 |
| Venous blood | 51.53 | 40.83 | 9.93 | 0.77 |
| Arterial blood..... | 33.29 | 17.69 | 14.61 | 1.00 |

W. D. H.

Cryoscopy of Blood. W. R. G. ATKINS (*Bio.-Chem. J.*, 1910, 5, 215--216).—A few observations on the value of Δ for the blood of various animals; some amount of variation is noted, and in some cases this may have been pathological.

W. D. H.

The Inorganic Constituents of the Blood in Vertebrates and Invertebrates and Its Origin. ARCHIBALD B. MACALLUM (*Proc. Roy. Soc.*, 1910, B, 82, 602--624. Compare Abstr., 1904, ii, 495).—Analyses of the ash of the blood in various animals are given and compared with the saline contents of the ocean at various geological periods. The arguments advanced are speculative, but the facts so far as at present collected support the author's previous conclusion that the saline composition of the sea determines that of the blood of marine organisms, and that the inorganic composition of vertebrate blood-plasma is an heirloom of life in the primeval ocean. The date of the origin of the vertebrate kidney is placed between the second eighth and the second sixth of the whole geological period.

W. D. H.

Hæmolysis. Is there a Cocaine Hæmolysis? GEORG FISCHER (*Pflüger's Archiv*, 1910, 134, 45--58).—Cocaine solutions have no specific hæmolytic power, but such hæmolysis as occurs is due to dissociation and liberation of hydrogen ions, or to decomposition of the cocaine molecule and liberation of hydrogen ions and alcohol.

W. D. H.

Origin and Destiny of Cholesterol in the Animal Organism. VII. The Quantity of Cholesterol and Cholesterol Esters in the Blood of Rabbits Fed on Diets containing Varying Amounts of Cholesterol. MARY T. FRASER and JOHN A. GARDNER (*Proc. Roy. Soc.*, 1910, B, 82, 559--568).—When cholesterol is given with the food, some is absorbed, and the free cholesterol and the cholesterol esters in the blood are increased. If phytosterol is given, this substance is partly absorbed, and the free cholesterol of the blood rises. Phytosterol does not appear in the blood as such.

The digitonin method for estimating cholesterol is very accurate.

W. D. H.

Action of Acids and Alkalis on the Artificial Anti-serum of the Ox, which is Hæmolytic to Rabbits. GIOVANNI MORUZZI (*Biochem. Zeitsch.*, 1910, 27, 498--515).—Hydrochloric acid completely inhibits the hæmolysis when present to the extent of 0.015*N*; it does

not destroy the hæmolytic power, for this again becomes evident on neutralisation. There is no destruction either of the amoceptor or the complement. Dilution with normal saline solution does not revive the process. Similar experiments with sodium hydroxide show many analogies to the action of hydrochloric acid. There is no increase in viscosity in either case.

W. D. H.

The Relationship between the Anti-trypsin of the Blood and that of the Urine. GOICHI HIRATA (*Biochem. Zeitsch.*, 1910, 27, 397—404).—In artificial nephritis in rabbits there is a great rise in the anti-trypsin of the urine and of the blood. In nephritis produced by uranium salts, the rise is first seen in the urine; in that produced by chromic acid, first in the blood; in spontaneous albuminuria and in that produced by mercuric chloride, the rise in both fluids is simultaneous.

W. D. H.

Inhibition of Precipitation by Precipitoids. WILHELM SPÄT (*Biochem. Zeitsch.*, 1910, 23, 7—15).—The experiments described show that the inhibition of precipitation produced by inactivated immune serum or normal serum is not brought about by a union between the inactive serum (precipitoid) and extracts of bacteria employed.

W. D. H.

Estimation of Adrenaline in Normal Blood and after its Injection by means of Physiological Methods. PAUL TRENDELENBURG (*Arch. exp. Path. Pharm.*, 1910, 63, 161—176).—The physiological test adopted was in principle that of Laewen (*ibid.*, 1904, 51, 415), namely, the measurement of the vaso-constrictor effect on the frog's hind limbs by the rate of outflow when perfused with the substance dissolved in Ringer's solution. The quantity of adrenaline in the blood stream of cats after an injection runs parallel to its pressor effect. As the blood pressure falls, the amount of adrenaline in the circulation sinks. Adrenaline thus resembles muscarine in its rapid disappearance.

W. D. H.

Specific Adaptation of Digestive Juices. I. Specificity of Gastric and Pancreatic Juice. E. S. LONDON and W. N. LUKIN. II. Specificity of Duodenal Mixed Juices. E. S. LONDON and R. S. KRYM. III. E. S. LONDON and N. DOBROWOLSKAJA (*Zeitsch. physiol. Chem.*, 1910, 68, 366—377).—I. From experiments on fistulous dogs, varying kinds of food placed in the intestine lead to specific variations in the quantity of bile and pancreatic juice secreted, but not to variations in the amounts of the pancreatic enzymes. When fat is introduced, there is no increase (five cases out of seven) in the lipase secreted in the "small stomach."

II. The same is true for the mixture of juices in the duodenum when the food is introduced into the lower jejunum and ileum.

III. There is similarly no adaptation of the enzymes of the intestinal juice. Oleic acid and amino-acids are specially powerful stimulants in regard to the amount of juice secreted.

W. D. H.

The Laws of Digestion and Absorption. VI. The Distance Law of Solution by Duodenal Juice. E. S. LONDON and C. SCHWARZ. VII. The Neutralisation Laws of Digestive Juices. E. S. LONDON and O. J. GOLMBERG. VIII. The Action of Various External Factors on the Secretion of Duodenal Juices. IX. Digestion of Carbohydrates. E. S. LONDON and A. P. KORCHOW (*Zeitsch. physiol. Chem.*, 1910, 68, 346—351, 352—357, 358—362, 363—365. Compare this vol., ii, 422).—VI. By experiments on dogs with fistulae, it was found that the effect of an acid peptone solution in calling forth the secretion of the pancreas and liver is not limited to the duodenum, but extends as far as the upper ileum, a distance of about 2 metres; this action in stimulating secretion diminishes analwards with the square root of the distance from the point of stimulation.

VII. The quantity of pancreatic juice is directly proportional to the square root of the concentration of the gastric juice, and its alkalinity inversely proportional. The total amount of alkali in the duodenal juices is inversely proportional to the square root of the gastric juice concentration.

VIII. Further laws are laid down in regard to the duodenal juices (bile, pancreatic juice, intestinal juice), in all of which the square root figures largely.

IX. Three hours after a meal of flesh and starch in a dog, the stomach contents contain the same amount of starch, although the amount given varies from 40 to 100 grams. W. D. H.

The Chemistry of Digestion and Absorption in the Animal Body. XL. The Study of Gastric Digestion on a Mixed Protein Diet. E. S. LONDON and C. SCHWARZ (*Zeitsch. physiol. Chem.*, 1910, 68, 378—380. Compare this vol., ii, 422).—Gastric digestion is specially furthered by those proteins (such as meat compared with egg-white) which stay longest in the stomach. W. D. H.

Digestion of Fat in the Stomach and Small Intestine, and the Effect of Lecithin on it. USUKI (*Arch. exp. Path. Pharm.*, 1910, 63, 270—293).—If lecithin or egg-yolk is mixed with milk, the rate of fat digestion is increased, and the contents leave the stomach sooner. The addition of lecithin lessens the amount of soaps in the intestine, and increases it (after egg-yolk) in the faeces; this is explained by absorption processes in the large intestine. The splitting of lecithin in the stomach occurs more quickly than that of neutral fats. Lecithin favours the saponification and digestion of neutral fats. In spite of its small percentage of lecithin, fat digestion is more favoured by egg-yolk than by lecithin itself; this is probably due to the fineness of the emulsion as well as the chemical nature of the fat in yolk. No lecithin was found in the intestine; it must therefore be split up either in the stomach or soon after its entrance into the duodenum. The observations were made on dogs and children. W. D. H.

Phosphorus Metabolism in the Animal Organism. FELIX ROGOZIŃSKI (*Bull. Acad. Sci. Cracow*, 1910, B, 260—312).—Sodium

phosphate, phytin, and lecithin, added to the diet of a grown dog, produce no marked change in nitrogenous metabolism. Sodium phosphate is excreted quantitatively in the urine. Lecithin when given is not found in the faeces; its phosphoric acid appears quantitatively as inorganic phosphate in the urine; the phosphorus of phytin appears to the extent of 30% as phosphoric acid in the urine; the remainder is found as phytin in the faeces. In opposition to the work of others, phytin in man causes no change in the excretion of nitrogen or phosphorus; a small part of the phosphorus is retained; the remainder appears as inorganic phosphate in the faeces. In contrast with the dog, human faeces contain abundant lecithin compounds. No inositol is found in human urine after feeding on phytin. The bacteria of human faeces are able *in vitro* to decompose phytin and produce inorganic phosphates from it. W. D. H.

Physiological Protoplasmic Metabolism and Purine Formation. F. MAREŠ (*Pflüger's Archiv*, 1910, 134, 59—102).—The various theories of the origin of purine substances, especially uric acid (for instance, the muscular theory, the leucocyte theory, etc.), are discussed at length. Purely chemical views are discountenanced, for the source of purine is to be sought in the physiological activity of the living cell. The constancy of uric acid excretion in individuals is true only for fasting periods, and considerable stress is laid on the importance of the work of the digestive organs as a means of increasing uric acid formation. The nucleus of the cell is the main part concerned, and the same is true for other active cell masses, for instance, malignant growths. The importance of the digestive glands is shown by the fact that pilocarpin raises the uric acid output. W. D. H.

The Metabolism of Some Purine Compounds in the Rabbit, Dog, Pig, and Man. LAFAYETTE B. MENDEL and JOHN F. LYMAN (*J. Biol. Chem.*, 1910, 8, 115—144).—The examination of tissue extracts has shown that in different animals the purine enzymes are differently distributed; the present experiments, in which purines were given either parenterally (in animals) or by the mouth (in man) support the view that the metabolic history of the purines varies in different animals. The difficulty man has in oxidising uric acid, as shown by its reappearance in the urine after parenteral administration, fits in with the examination of tissue extracts, in which no uricolytic enzyme is found in human tissues. On the other hand, a large proportion of the uric acid introduced into the rabbit does not reappear as such. After injection of adenine in dogs and rabbits, there is a relatively large output of unaltered adenine, and but little uric acid or allantoin. If guanine is given, there is a larger output of allantoin, xanthine, and uric acid. Guamase is more widespread in rabbit and dog tissues than adenase. In the pig, uric acid is not the chief end-product of purine metabolism. In man, the protocols given emphasise the fact that all the ordinary purines lead to an increase of exogenous uric acid, with but little influence on the elimination of purine bases in the urine. W. D. H.

Cleavage of Histidine in the Organism of the Dog. ERIC ABDERHALDEN, HANS EINEBECK, and JULIUS SCHMID (*Zeitsch. physiol. Chem.*, 1910, 68, 395—399. Compare Abstr., 1909, ii, 906).—Intravenous administration of histidine in a dog does not lead to increase in the excretion of allantoin in the urine. If given by the mouth, the increase of allantoin is very slight, and sometimes absent. Very little of the histidine given (0.4 out of 20 grams) is recoverable as such in the urine. Nucleic acid raises the allantoin excreted. W. D. H.

Influence of the Removal of Fragments of the Gastro-intestinal Tract on the Character of Nitrogen Metabolism. III. **The Excision of the Stomach.** A. CARREL, GUSTAVE M. MEYER, and PHILIP A. LEVINE (*Amer. J. Physiol.*, 1910, 23, 369—380. Compare this vol. ii, 323).—Two dogs were operated on, and in one of them the extirpation of the stomach was quite complete. Before the tenth week there is high nitrogen retention, probably because the pancreatic and intestinal secretions are interfered with, but after this date no nitrogen retention occurs. Parenterally introduced protein was completely retained in the organism. W. D. H.

Imbibition of the Intestinal Mucous Membrane with Sodium Chloride and Sulphate Solutions of Different Concentrations. G. QUAGLIARIELLO (*Biochem. Zeitsch.*, 1910, 27, 516—529).—The present experiments deal with sodium sulphate; they support Loeper's conclusions, and show that the salt has an inhibitory influence on imbibition, but this is regarded as a secondary effect; the opinion is held that it is the ions working on the intestinal muscle which explains the purgative action of the salt. W. D. H.

The Influence of Sugar on the Permeability of the Intestinal Membrane. ERNST MAYERHOFFER and ERNST STEIN (*Biochem. Zeitsch.*, 1910, 27, 376—384).—The permeability of the intestinal mucous membrane of rabbits, removed after death, is increased towards normal ammonium chloride solution by placing the membrane in a 5% solution of dextrose. Supposing the same to be true *in vivo*, cases of dyspepsia due to excess of sugar are explicable. W. D. H.

The Fate of Sucrose after Parenteral Introduction in Animals. LAFAYETTE B. MENDEL and ISRAEL S. KLEINER (*Amer. J. Physiol.*, 1910, 26, 396—406).—When sucrose is introduced intraperitoneally or subcutaneously into dogs and cats in doses of 1—2 grams per kilo. of body-weight, about 65% is recovered in the urine, and a reducing fermentable substance is also sometimes present. The excretion begins within a few minutes, and is usually completed in thirty-six hours. The actual figure, however, varies with different conditions (fasting, pregnancy, etc.). Sucrase was not found in the blood; nevertheless, as Abderhalden and Brahm showed, there is a possibility of sucrose digestion in the blood, which may account for the disappearance of part of the sugar. W. D. H.

The Value of Beer-extract and Beer in the Human and Animal Organism. WILHELM VÖLTZ, RUDOLF FÖRSTER, and AUGUST BACHDREXEL (*Pflüger's Archiv*, 1910, 134, 133—258).—The dry residue of beer extract elevates the absorption of non-nitrogenous material, especially fat. Approximately 40% of the nitrogenous substance is absorbed. Observations both on men and dogs are given, and deductions as to its nutritive value coincide in the main with those of Atwater and Benedict. Observations with toxic doses are also given. The general trend of the article is a defence of the use of alcohol in moderation, especially in the form of beer. W. D. H.

Digestibility of Bleached Flour. ELBERT W. ROCKWOOD (*J. Biol. Chem.*, 1910, 8, 327—340).—Experiments on the artificial digestion of unbleached flour, as compared with specimens of the same flour bleached with nitrogen peroxide, show no loss of digestibility, and in some cases the bleached specimens digested more rapidly than the unbleached. W. D. H.

The Value of the Cleavage Products of Protein in the Animal Organism. XVI. EMIL ABDERHALDEN and AKIKAZU SUWA (*Zeitsch. physiol. Chem.*, 1910, 68, 416—420. Compare this vol., ii, 877).—A dog was fed exclusively on the cleavage products of flesh without admixture of fat or carbohydrate. The preparation used was "ereptone," made from meat by the successive action of gastric, pancreatic, and intestinal juices. Vomiting and diarrhoea were to some extent overcome by giving the food carefully in small doses through a gastric fistula. The animal gained in weight, and put on flesh. The conclusions drawn by Voit and Zisterer (this vol., ii, 425) from somewhat similar experiments are criticised. W. D. H.

The Temperature-coefficient of Cytolysis in the Unfertilised Egg of the Sea-Urchin. A. R. MOORE (*Quart. J. exper. Physiol.*, 1910, 3, 257—260).—The temperature-coefficient for the process of cytolysis of sea-urchin eggs in sea-water was found to be about 200 for a difference in temperature of 10°. The same figure was calculated from Gros's data for hæmolysis. W. D. H.

Differentiation of Proteins of Closely Related Species by the Precipitin Reaction. D. A. WELSH and H. G. CHAPMAN (*J. Hygiene*, 1910, 10, 177—184).—It is possible to distinguish heterologous proteins of closely related species by precipitin interactions arranged with regard to the fact that in the conditions of experiment the weight of precipitates is proportional to the weight of the anti-serum employed. This is illustrated by experiments with the albumin prepared from different birds' eggs. The experiments support the authors' previously expressed view that the anti-serum is the main source of the precipitate in the precipitin reaction. W. D. H.

Chemico-Physical Investigations on the Crystalline Lens. FILIPPO BOTTAZZI and NOÈ SCALINCI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 162—169. Compare this vol., ii, 143).—The authors have

investigated the influence of various chlorides (those of sodium, potassium, calcium, and magnesium) and of various sodium salts (chloride, nitrate, acetate, sulphate, and tartrate) on the imbibition of water by the crystalline lens. Solutions of the following concentrations were employed: $N/5$, $N/50$, $N/100$, $N/150$, $N/200$. In all cases the imbibition was less than that which occurs when the lens is immersed in pure water, and the decrease was greater in the case of the $N/5$ solutions than with the weaker ones. As regards the specific actions of the different ions (for the elucidation of which the results with the strongest solutions are the most trustworthy), it appears that the bivalent cations (magnesium and calcium) diminish the imbibition more than the univalent cations (sodium and potassium), although there are considerable irregularities, which are still more pronounced in the case of the different anions.

R. V. S.

Heart Metabolism. I. Metabolic Investigations of the Surviving Warm-blooded Heart. ERWIN KONDE (*Zeitsch. physiol. Chem.*, 1910, 68, 181—235).—Previous work on the isolated mammalian heart, such as that by Locke and Rosenheim on its capacity to utilise sugar, or of Barcroft and Dixon on its gaseous metabolism, is on the whole confirmed; the special feature of the apparatus here used is that simultaneously means are adopted for measuring the work of the heart. The metabolic changes run parallel to the amount of work done. In the presence of sugar, not only is sugar burnt, but often constituents in the heart itself (reserve material) are burnt also, and thus leads to the production of carbon dioxide. When sugar or other nutritive material is absent, those reserve materials are alone utilisable; these probably originate from fat and protein, and the hypothesis is put forward that the heart forms a sort of internal secretion in which glycolysis occurs.

W. D. H.

The Injury to the Heart's Activity Produced by Glyoxylic Acid. R. H. KAHN and EMIL STARKENSTEIN (*Pflüger's Archiv*, 1910, 133, 579—597).—The bulk of this paper has but little chemical interest. Cardiac activity was studied by the cardio-electrogram, and the causes of pulsus alternans are discussed. In glyoxylic acid poisoning, this symptom is pronounced.

W. D. H.

Union Relationships of Heart Muscle and Digitalis. B. SCHLIOMENSUN (*Arch. exp. Path. Pharm.*, 1910, 63, 294—302).—From the hearts of men and animals a group of substances can be isolated, namely, the alcohol-soluble phosphatides, which appear to have a special capacity to combine with the active material in digitalis. The corresponding fractions from the skeletal muscles and liver do not possess this property. It is not possible at present to say what are the definite chemical substance or substances that participate in this specific reaction.

W. D. H.

The Formation in the Animal Body of l - β -Hydroxybutyric Acid by the Reduction of Acetoacetic Acid. HENRY D. DAEIN (*J. Biol. Chem.*, 1910, 8, 97—104).—The liver contains not only an

oxylase which converts β -hydroxybutyric acid into acetoacetic acid, but also a reductase which produces the reverse change. The view taken of l - β -hydroxybutyric acid acidosis is that its main underlying cause is defective catabolism of acetoacetic acid. The conclusions are supported by experiments. The question is discussed whether the phenomena are due to the reversible action of one enzyme, or to the antagonistic action of two enzymes. The latter hypothesis fits in best with the facts.

W. D. H.

The Degradation of Carboxylic Acids in the Animal Body.
XII. A New Method of Formation of β -Hydroxybutyric Acid in the Animal Body. ERNST FRIEDMANN and C. MAASE (*Biochem. Zeitsch.*, 1910, 27, 474—490. Compare this vol., ii, 794, 795).—In experiments on perfusion of the dog's liver with ox-blood a fair amount of l - β -hydroxybutyric acid is formed, in most cases without the addition to the perfusing liquid of any substance which yields acetoacetic acid. If sodium acetoacetate is added to the perfusing blood, a large amount disappears, and from 42 to 62% of this is accounted for by the l - β -hydroxybutyric acid formed. If sodium butyrate, or especially isovalerate, is added, there is a large formation of both acetoacetic and β -hydroxybutyric acids. Similar results were obtained in experiments with pounded liver substance. The agent which converts acetoacetic acid into l - β -hydroxybutyric acid is termed *keto-reductase*.

W. D. H.

The Decomposition of Acetoacetic Acid by Enzymes of the Liver. II. ALFRED J. WAKEMAN and HENRY D. DAKIN (*J. Biol. Chem.*, 1910, 8, 105—108).—Further facts are given in relation to the liver reductase; the primary product of its action on acetoacetic acid is not acetic acid, but l - β -hydroxybutyric acid.

W. D. H.

Uric Acid Metabolism in Dogs. H. ACKROYD (*Bio.-Chem. J.*, 1910, 5, 217—224).—The liver of dogs when perfused with normal saline solution produces a small quantity of allantoin. When sodium urate is added to the perfusion fluid, a part of it is destroyed; part only of this is recovered as allantoin; no uric acid could be isolated. The dog's liver has not the power to destroy allantoin.

W. D. H.

The Formation of Uramido-acids in the Organism. I. FRITZ LIPPEICH (*Zeitsch. physiol. Chem.*, 1910, 68, 277—292).—The formation of uramido-acids in the body is important from the standpoint of uric acid formation, and former work on the question is quoted at length. The present experiments on the action of the dog's liver in the formation of such acids gave negative results.

W. D. H.

Liver Pigments of Invertebrates. RAFFAELE PALADINO (*Biochem. Zeitsch.*, 1910, 23, 56—59).—From the liver of invertebrates (molluscs being mainly used), two pigments were obtained, one soluble in water, the other in chloroform or alcohol. The former is rich in iron, and gives a continuous spectrum, the latter poor in, or free from, iron gives absorption bands. The same pigments are stated to be also obtainable from the vertebrate liver.

W. D. H.

Study of Autolysis by Physico-chemical Methods. II. ROBERT L. BENSON and H. GIDEON WELLS (*J. Biol. Chem.*, 1910, 8, 61-67. Compare *ibid.*, 1907, 3, 35).—Autolysis is usually measured by the change in the amount of nitrogen contained in forms coagulable and not coagulable by heat, but it is shown by experiments with dog's liver, blood-serum, and blood that autolysis can be followed much more satisfactorily by freezing-point determinations supplemented by electrical conductivity measurements. Toluene was found to be the most satisfactory antiseptic in these experiments.

In agreement with Baer and Loeb (*Abstr.*, 1905, ii, 734), the authors find that the inhibiting effect of serum on autolysis (the effect of dog serum on the autolysis of dog liver was observed) is scarcely affected by heating the serum at 85° or 95° for thirty minutes. In other cases, the inhibiting effect of serum appears to be diminished by heating, but there seems to be some discrepancy in the results obtained when the autolytic changes are measured by physical or chemical means, and when they are measured by the histological changes taking place in the cells. G. S.

The Occurrence of Free Guanosine in the Pancreas. PHOEBUS A. LEVENE and WALTER A. JACOBS (*Biochem. Zeitsch.*, 1910, 26, 127-130).—The separation of guanylic acid from the pancreas was found to be difficult, owing to the presence of guanosine, which is regarded as being in the free stato. In fact it is sometimes more abundant than the acid. W. D. H.

Ethyl Acetate Extracts of Organs and their Behaviour in Autolysis. IV. and V. KENRO KONDO (*Biochem. Zeitsch.*, 1910, 27, 427-435, 436-441. Compare this vol., ii, 791).—The present experiments with kidney, spleen, and blood were carried out in the same way as in previous work on the liver. The results with kidney and spleen (to some extent) were very similar, and there appears to be present in these organs substances other than cholesterol containing hydroxyl groups, the quantity of which increases in the warm. In the case of the blood, there was no evidence of any enzyme either in the corpuscles or plasma capable of splitting cholesterol esters. The acetyl number remains unchanged after autolysis. This is not due to the presence of an inhibiting agent, for the increase occurs when liver extract is added. W. D. H.

Formation of Oxalic Acid in the Organism. HERMANN JASTROWITZ (*Biochem. Zeitsch.*, 1910, 28, 34-47).—Oxalic acid can arise from uric acid, aminodicarboxylic acids, and carbohydrates. In intermediate metabolism, it is formed especially in the spleen, and probably also in the liver and muscles (in dogs). In anomalies of nuclein metabolism (gout, leucæmia), increased oxalic acid formation occurs very seldom, but it may occur in diabetes. W. D. H.

Metabolic Disturbances after the Extirpation of both Suprarenal Glands. OSWALD SCHWABZ (*Pflüger's Archiv*, 1910, 134, 259-288).—The animals used were rats; when both the suprarenals

are removed, the hepatic glycogen is much reduced or disappears entirely; this is regarded, not as due to general marasmus, but as a specific effect of the operation; when then fed on bread, glycosuria is produced; with feeding on pure dextrose, the glycogen returns in some measure to the liver. The administration of lævulose leads neither to glycogen formation nor to lævulosuria; it is apparently completely utilised in the body; feeding on sucrose leads to glycogen formation in virtue of its dextrose component; after feeding on starch, alanine, or aspartic acid, the liver is free from glycogen. Phloridzin is highly toxic to these animals; it produces glycosuria; they are also sensitive to adrenaline injections. A sugar mobilising function is assigned to adrenaline.

W. D. H.

Toxic Action of Compound on Isolated Muscle Regarded as a Chemical Change. VICTOR H. VELEY (*Quart. J. Exper. Physiol.*, 1910, 3, 233—249).—From the experiments previously recorded by the author (mainly in conjunction with Waller, this vol., ii, 55, 228, 331, 524), the conclusion is drawn that living muscular tissue behaves as if it contained, not only proteins as such, but even their products of decomposition or hydrolysis, or, in other words, the living muscle behaves like a lifeless chemical reagent; the results obtained are not greatly inferior in accuracy to those obtained in reactions between highly refined chemical compounds under rigid physical conditions.

W. D. H.

The Quantitative Relations of Diastase in Different Organs of Different Animals. GOICHI HIRATA (*Biochem. Zeitsch.*, 1910, 27, 385—396).—In estimating the diastase, Wohlgemuth's method and notation are employed. The pancreas, spleen, liver, blood, kidney, and other organs of various mammals, birds, fishes, and amphibians were investigated. The pancreas in all cases contains most diastase; the blood and liver generally come next; in rats on a starch diet, the diastase value of the pancreas rises from 300 to 400-fold.

W. D. H.

Presence of Glycuronic Derivatives in Beef Bouillon. LÉON GRIMBERT and E. TURPAUD (*J. Pharm. Chim.*, 1910, [vii], 2, 289—292).—The presence of reducing substances in aqueous extracts of beef has long been known, and the action has been variously ascribed to dextrose, maltose, isomaltose, pentoses, or glycuronic acid.

The author finds that bouillon, defaecated by mercuric nitrate solution, or boiled with hydrochloric acid, yields with phenylhydrazine a mixture of phenylglucosazone and phenylglycosazone (Grimbert and Bernier, this vol., ii, 163). Glycuronic derivatives can also be detected by Tollens' reagent in bouillon defaecated by mercuric acetate, and from which the dextrose has been eliminated by the action of *Bacterium coli*.

T. A. H.

Manganese of the Tissues of Lower Animals. HAROLD C. BRADLEY (*J. Biol. Chem.*, 1910, 8, 237—250. Compare Abstr., 1907, ii, 567).—Analyses of the amount of manganese in the different parts of various mussels are given. It is not regarded as merely adventitious; it is constantly present, and in spite of the small amount

present in the muscular tissue (which has a low order of activity in these animals), probably plays a rôle in respiration. In lakes poor in manganese (and poor also in the *Crenothrix* and diatoms which contain large amounts of manganese and form the food of the mussels), mussels cannot live.

W. D. H.

Alcohol Oxydase in Animal Tissues. FR. BATTELLI and (Mlle.) LINA STERN (*Biochem. Zeitsch.*, 1910, 28, 145—168).—*Alcohol-oxydase* (alcoholase) is an enzyme which acts chiefly on ethyl alcohol, and converts it into acetic acid by absorption of molecular oxygen; aldehyde is an intermediate product; it also oxidises aldehyde directly. The enzyme does not decrease in amount in the tissues one or two days after death. It is most abundant in the liver, especially of the horse; the amount in human liver is relatively small; the kidneys also contain it, but the amount in other organs is very small. It acts neither in acid nor in strongly alkaline media; it acts best in faintly alkaline media. Addition of spleen to the liver increases the effect. Hydrogen peroxide has no effect.

W. D. H.

Further Investigations on the Use of Silk Peptone for the Detection of Peptolytic Enzymes. EMIL ABDERHALDEN and EUGEN STEINECK (*Zeitsch. physiol. Chem.*, 1910, 68, 312—316).—Details are given in regard to the best methods for obtaining silk peptone. Slices of organs (for instance, kidneys) placed in the peptone solution become, if a peptolytic enzyme is present, covered with tyrosine crystals. Whether healthy and pathological organs vary in this direction is to be further investigated. In the developing chick, peptolytic enzymes appear in the tissues at seventh to eighth day of incubation; in the pig embryo, in nearly all the tissues after the thirty-seventh day of development.

W. D. H.

Enzymatic Acceleration of Cannizzaro's Aldehyde Transformation by Tissue Extracts. I. JAKOB PARNAS (*Biochem. Zeitsch.*, 1910, 28, 274—294).—Animal tissues usually contain both fatty acid and the corresponding alcohol, and it is suggested that these are both derived from aldehyde by the Cannizzaro transformation. The liver, but not the lungs, contains a soluble ferment which accelerates this transformation, so that it takes place with aldehydes which otherwise tend to undergo aldol condensation. Quantitative production of the corresponding acid and alcohol was obtained from *n*- and isovaleraldehydes, isobutaldehyde, and propaldehyde, also from heptaldehyde after three hours' action of pig or ox liver. Benzaldehyde yielded a small quantity of alcohol; salicylaldehyde was not attacked. The name *aldehydemutase* is proposed for the enzyme.

E. F. A.

Enterolipase. B. C. P. JANSSEN (*Zeitsch. physiol. Chem.*, 1910, 68, 400—415).—As Lombroso showed, a mixture of bile and oleic acid stimulates the secretion in the intestine of a juice rich in lipase. Oleic acid alone has no such effect. Bile alone has not so great an effect as the mixture. These experiments were made with intestinal

loops. *In vitro*, the addition of bile increases the lipolytic action of the juice. Soap solution causes the secretion of a feebly lipolytic juice; *in vitro*, soap inhibits lipolytic action, but a small addition of alkali increases it. The addition of bile acids to bile increases its power of stimulating the secretion of lipase, and the effect of the mixture of bile and oleic acid is probably due to the bile acids. The group in the bile acid molecule to which this is due is to be the subject of renewed investigation.

W. D. H.

Occurrence of Serine in Human Perspiration. GUSTAV EMBDEN and HERMANN TACHAU (*Biochem. Zeitsch.*, 1910, 28, 230—236).—Hitherto only two nitrogenous substances, carbamide and ammonia, have been isolated from perspiration. From fresh perspiration, fairly large quantities of serine are now isolated by means of β -naphthalene-sulphonic acid. This method is advantageous in separating serine from the mixture of protein decomposition products obtained by acid hydrolysis.

E. F. A.

The Production of Glycosuria in Relation to the Activity of the Pancreas. IVOR L. TUCKER (*J. Physiol.*, 1910, 41, 88—144).—Glycosuria due to anæsthesia and operation is probably not influenced by the pancreatic factor; neither is there evidence that the carbohydrate in the diet stimulates the pancreas to an increase in its internal secretion. Glycosuria following fistula or ligature of the thoracic duct is probably due to the anæsthetic employed and to disturbance of nerves, but as the internal secretion of the pancreas finds its way into the circulation by this duct, that may possibly be a subsidiary factor. The glycosuria associated with morphine and ether narcosis is the result of the rapid production of sugar from hepatic glycogen, other carbohydrates in the body, and also from fat. The sugar in the blood of cats exhibiting experimental glycosuria has a reducing power equal to that of dextrose.

W. D. H.

Nature of Bence-Jones Protein. OWEN T. WILLIAMS (*Bio.-Chem. J.*, 1910, 5, 225—229).—The protein was obtained in the urine of a case of myeloma; it is shown that it varies in composition from time to time even in the same case, and probably the true explanation lies in the fact that in the disintegration of bones and tendons, chondro-mucins are liberated, which are more or less broken up, and thus excreted differently according to the stage of the disease. The protein in the present case gave the typical reactions of the Bence-Jones protein. It resembles mucoid in that it contains a carbohydrate radicle and a high percentage of sulphur. The latter, however, varies, and when it sinks the amount of ethereal sulphate in the urine rises.

W. D. H.

Diastase in the Blood and Urine of Rabbits. GOICHI HIRATA (*Biochem. Zeitsch.*, 1910, 28, 23—28).—In experimental nephritis in rabbits, the diastase in the urine sinks; this is regarded as due to lessened functional activity of the kidney cells, and the decrease is greatest in cases where the injury is greatest. The rise of diastase in

the blood which accompanies this is regarded as due to defective elimination by the kidneys.

W. D. H.

Metabolism in Addison's Disease. H. BEUTENMÜLLER and FELICITAS STOLTZENBERG (*Biochem. Zeitsch.*, 1910, 28, 138—144).—In the case of Addison's disease investigated there was no important departure from the normal in nitrogen metabolism; on an abundant diet, the patient retained nitrogen; the administration of adrenal tablets had no effect.

W. D. H.

The Excretion of Creatine in Diabetes. R. A. KRAUSE (*Quart. J. Exper. Physiol.*, 1910, 3, 289—296).—A full account of experiments already published as a preliminary communication (see Krause and Cramer, this vol., ii, 793).

W. D. H.

Prophylaxis in Malaria. Action of Small Continuous Doses of Quinine on the Development of the Animal Organism and its Application in Infectious Disease. ALBERT GRAZIANI (*Arch. Hygiene*, 1910, 73, 39—80).—Injection of quinine hydrochloride for one hundred days in doses of 0.005 gram per kilo. of body-weight in young rabbits and guinea-pigs delays growth, and in adult animals lessens their weight. There is no change in the corpuscles or hæmoglobin of the blood; the bactericidal power of the lungs or of the serum is unaltered; so also are the opsonic index and the agglutinating action of the blood in reference to typhoid bacilli; in fact, in most cases the immunising power of the blood is diminished. The animals which had received quinine are much less resistant towards infection (typhoid, anthrax, cholera, pneumonia) than the control animals. Observations on the blood of man show the same results, and the conclusion is drawn that the same loss of resistance occurs in man also.

W. D. H.

Atoxyl. IV. FERDINAND BLUMENTHAL (*Biochem. Zeitsch.*, 1910, 28, 91—96. Compare Abstr., 1909, ii, 255).—The use of atoxyl preparations and of its various iodine and bromine derivatives in syphilis is suggested. The present experiments are mainly on animals to discover the relative toxicity of these compounds; the silver salts are less poisonous than those of mercury.

W. D. H.

Absorption of Hydrogen Chloride by Animals. KARL B. LEHMANN and ARTHUR BURCK (*Arch. Hygiene*, 1910, 72, 343—357).—In tracheotomised rabbits, the amount of hydrogen chloride absorbed in the first hour varied between 58 and 80% of the amount inspired; higher figures were obtained when the gas was given through the nose. The absorption increases with the depth of respiration. In the second hour there was no marked falling off in the rate of absorption; experiments lasting more than two hours were not made.

W. D. H.

Absorption of Chloroform, Carbon Tetrachloride, and Tetrachloroethane in Animals and Man. KARL B. LEHMANN and HASEGAWA (*Arch. Hygiene*, 1910, 72, 327—342).—The experi-

ments on two men were carried out by estimating the chloroform in the inspired and expired air, the difference giving the amount absorbed. In periods of five to ten minutes from 53 to 73% of the chloroform given was absorbed. In experiments for longer periods, the amount absorbed was greatest in the first five minutes, and then gradually declined. In rabbits the same falling off was noticed, but the total absorption was less than in man. Administration was either made by the nose or by the tracheal tube, but the method made no difference. Similar figures (in rabbits) were obtained with carbon tetrachloride and tetrachloroethane.

W. D. H.

Influence of Gases on the Organism. XV. Hydrogen Arsenide. L. O. DUBITZKI (*Arch. Hygiene*, 1910, 73, 1—38).—This gas was estimated in the air volumetrically either by calcium chloride, silver nitrate, or potassium iodate. In cats, 0.005% is fatal in sixty to ninety minutes, 0.004% in three hours. A prominent symptom is hemolysis leading to hæmoglobinuria. The absolute fatal dose varies from 8.7 to 13.7 milligrams.

W. D. H.

Action of Radium Emanations on the Development of Animal Eggs. II. OSCAR HERTWIG (*Sitzungsber. K. Akad. Wiss., Berlin*, 1910, 39, 751—771).—Experiments on various eggs confirm the author's previous conclusions. The main interest of the paper relates to the action of the radium emanations on the sperm of the frog. After exposures varying from five minutes to twelve hours, the spermatozoa becomes more or less altered, but the nucleus is the most affected. These spermatozoa are still capable of fertilising the eggs, although development is slow in cases of long exposure and abnormal embryos are formed. This is regarded as an additional proof that the nuclear substance is the most important part of the male cell in fertilisation.

W. D. H.

Action of Radium Bromide on the Skin of the Rabbit's Ear. J. O. WAKELIN BARRATT (*Quart. J. exper. Physiol.*, 1910, 3, 261—270).—A disk of radium bromide placed on the ear of the rabbit produced a ring of pigmentation corresponding with the edge of the disk. Within the ring more or less depigmentation occurred. The deposit of pigment took place chiefly in the epidermis. In albino rabbits and with human skin no such effects were observed.

W. D. H.

The Pharmacological Action of Uranium. D. E. JACKSON (*Amer. J. Physiol.*, 1910, 26, 381—395).—The action of uranium is generally believed to resemble that of cyanides, but there are many points of difference. Intravenously administered as the sodium uranium tartrate there is no increase in the flow of lymph from the thoracic duct even in lethal doses. The rise of arterial pressure is much more pronounced than that produced by cyanides, and the stimulating action on respiration is less marked. Blood coagulation is prevented, probably by union of the metal with one or more of the protein factors in the process. Further, there is no change in the hæmoglobin. Cyanides binder the guaiacum reaction with extract of potato peelings; uranium does not.

W. D. H.

Behaviour of Iodoso-, Iodoxy-, and Iodonium Compounds in the Animal Organism. II. Behaviour of Iodoxybenzene. RICCARDO LUZZATTO and G. SATTA (*Arch. Farm. sper. Sci.*, 1910, 9, 241—253. Compare this vol. ii, 433).—Even in quantities five times greater than the toxic dose of iodosobenzene, iodoxybenzene does not cause death in dogs, rabbits or frogs. The effects it produces are similar in kind to those of the former substance, but its action is much weaker and slower. It is converted in the organism into iodo-benzene, for iodophenylmercapturic acid can be isolated from the urine, and its lower toxicity is probably due to the fact that this reduction occurs more easily than in the case of iodosobenzene. Iodoxybenzene does not exhibit any curare-like action on frogs.

R. V. S.

The Behaviour of β -p-Hydroxyphenyl- α -lactic Acid and p-Hydroxyphenylpyruvic Acid in the Surviving Liver. ERNST SCHMITZ (*Biochem. Zeitsch.*, 1910, 28, 117—120).—Neubauer and Falta have shown that those aromatic substances the ring of which is easily burnt in the body are excreted in alcaptonuria as homogentisic acid, whereas those which are not, or only with difficulty, broken up have no such influence on the excretion of homogentisic acid. Embden, Salomon, and Schmidt have shown that the former group leads in the isolated liver to formation of acetoacetic acid, whereas the latter does not. In the present experiments on liver perfusion this is confirmed; β -p-hydroxyphenyl- α -lactic acid does not yield homogentisic acid, and leads to a negligible formation of acetone substances in the liver; p-hydroxyphenylpyruvic acid leads to homogentisic acid formation in alcaptonurics and to an abundant formation of acetone substances in the surviving liver.

W. D. H.

Chemical and Physiological Properties of Triphenylstibine Sulphide. Behaviour of this Substance in the Animal Body. LUDWIG KAUFMANN (*Biochem. Zeitsch.*, 1910, 28, 67—88, 86—90. Compare Abstr., 1908, i, 1031).—Triphenylstibine sulphide has the power to produce the evolution of oxygen from hydrogen peroxide and other peroxides; the sulphur is split off and oxidised to sulphuric acid, whilst the residue is oxidised to antimony oxide or hydroxide and precipitated as sulphate by the sulphuric acid. The reaction runs quantitatively at a temperature of 36—37°. The sulphite is one hundred times more active than ordinary sulphur.

The therapeutic use of the sulphide in cases (for instance, of skin disease) where sulphur is usually employed appears from a few preliminary observations and experiments to be justifiable.

W. D. H.

Chemical Structure and Sympathomimetic Action of Amines. GEORGE BARGER and HENRY H. DALE (*J. Physiol.*, 1910, 41, 19—59).—The action of adrenaline on the sympathetic is termed sympathomimetic, and is also shown by a large series of amines, the simplest being primary fatty amines. The action increases with approximation to adrenaline structure. The amines active in this way

are primary or secondary; the quaternary amines corresponding with the aromatic members of the series have an action like that of nicotine. The optimum carbon skeleton for sympathomimetic activity consists of a benzene ring with a side-chain of two carbon atoms, the terminal one bearing the amino-group. Another optimum condition is the presence of two phenolic hydroxyls in the 3:4 position relative to the side-chain; when these are present, an alcoholic hydroxyl still further intensifies the activity. A phenolic hydroxyl in the 1 position does not increase the activity. Catechol has no such activity. The methyl-amino-group, including adrenaline, reproduces inhibitory sympathetic effects more readily than motor effects; the opposite is true for the primary amines of the same series. Instability and activity show no parallelism in the series.

W. D. H.

The Fate of *p*-Hydroxyphenylethylamine in the Organism. ARTHUR J. EWINS and PATRICK P. LAIDLAW (*J. Physiol.*, 1910, 41, 78—87).—This amine is converted in part in the body into *p*-hydroxyphenylacetic acid; the surviving liver can effect this change, so also can the plain muscle of the uterus, but not that of the lung vessels. The isolated heart causes complete destruction of the amine. The amine is less readily converted into hydroxyphenylacetic acid than the primary amine, and hordenine, the tertiary base, still less readily than the secondary base.

W. D. H.

The Behaviour of Veronal (Sodium Veronal) in the Animal Body, after One Administration, and in the Chronic Condition. C. BACHEM (*Arch. exp. Path. Pharm.*, 1910, 63, 228—241).—After the subcutaneous injection of small doses of veronal, about 90% appears in the urine; in larger doses this sinks to 45—50% whether the drug is given in one or successive doses. The faeces contain only a small quantity, so about half is destroyed in the body, how or why is unknown. Small doses do not influence the well-being of the animals used. After three days, only small amounts are still found in the urine and organs. Its affinity for brain tissue is doubtless related to its narcotic properties. Even after large doses, a small fraction only is found in the stomach some hours later. In acute poisoning, the stomach must therefore be washed out early if it is to be of any avail.

W. D. H.

The Prophylactic Action of Atropine in Immediate Anaphylaxis of Guinea Pigs. III. JOHN AUER (*Amer. J. Physiol.*, 1910, 26, 439—452).—Guinea pigs sensitised by the subcutaneous injection of 1 to 2 c.c. of horse-serum reach their maximum sensitiveness about the ninth week, and this is then maintained for at least twenty-three weeks (the longest interval tested). Atropine was used as a prophylactic, as the symptoms of anaphylaxis are mainly due to contraction of bronchial muscles. Experimentally, atropine was found to be of distinct therapeutic utility. Without atropine, the death rate was 75%, with it only 28%.

W. D. H.

The Clinical Application of Ergotamine (Tyramine). ALFRED CLARK (*Bio.-Chem. J.*, 1910, 5, 236—242).—Tyramine given by the

mouth to a healthy subject in doses of 30 to 100 mg. causes a slight rise of blood-pressure which lasts some hours. When injected hypodermically (20 to 50 mg.), the rise is rapid and well marked, lasting about twenty minutes. When similarly given in cases of "shock," the blood-pressure rises slightly.

W. D. H.

Action of Curarine and Allied Substances. RUDOLF BOENIG (Arch. exp. Path. Pharm., 1910, 63, 177—227).—The direct excitability of skeletal muscle (frog) to induction shocks remains unaltered even by large doses of curarine, but the excitability varies in different parts. Towards condenser discharges, the effects are variable, as also they are in normal muscles. Muscles can easily be poisoned with curarine by immersing them in a solution of the drug. The great toxicity of the drug comes out when it is compared with other ammonium derivatives; the following relative figures are given: Choline, 0.35; tetraethylammonium, 0.125; trimethylethylammonium, 0.015; neurine, 0.012; tetramethylammonium, 0.005; muscarine, 0.0025; trimethylvaleryl ammonium (valearine), 0.001; curarine, 0.00001.

W. D. H.

Elementary Action of Digitalis Substances. RUDOLF MAGNUS and (Miss) S. C. M. SOWTON (Arch. exp. Path. Pharm., 1910, 63, 255—262).—Observations by the authors confirm Straub's views on the action of the digitalis group. The increased activity of the heart can be shown, not only in the intact animal, but also on the isolated heart. Illustrative experiments on the effect of strophanthin are given in full.

W. D. H.

The Concentration of Ammonia in the Blood of Cats and Dogs necessary to Produce Ammonia Tetany. CLARA JACOBSON (Amer. J. Physiol., 1910, 26, 407—412).—Ammonium carbonate was injected intravenously, and the concentration in the blood found necessary to produce tetany is identical with the concentration of ammonia in the blood when tetany occurs as a result of removal of the parathyroids. In the latter condition the liver is depressed in its power to destroy ammonia.

W. D. H.

Antimony Poisoning in Compositors. P. SCHRUMPF and B. ZABEL (Arch. exp. Path. Pharm., 1910, 63, 242—254).—Various symptoms presented by compositors could not be attributed to lead poisoning, but are due to antimony; the blood conditions underlying this are a slight leucocytosis, but a great excess of eosinophile cells. Similar conditions can be produced artificially by antimony in rabbits. No drug treatment is suggested; mere cessation of work in the men, or cessation of antimony dosage in animals, leads rapidly to a return to normal conditions.

W. D. H.

The Comparative Toxicity of Theobromine and Caffeine as Measured by their Direct Effect upon the Contractility of Isolated Muscle. VICTOR H. VELEY and AUGUSTUS D. WALLER (Proc. Roy. Soc., 1910, 82, B, 568—574).—Caffeine produces con-

tracture and finally abolition of contraction in muscle. With caffeotannic acid the admixture with tannic acid retards the change. Theobromine causes a similar effect, its toxic value compared with that of caffeine being 1·7:1 for equal molecules, or 1·8:1 for equal weights. The introduction of the methyl group into theobromine to form caffeine lowers the toxicity, a result converse to that found in certain other organic compounds. Experiments are also recorded with extracts of tea and coffee; "caffeine-free" coffee has but little action.

W. D. H.

The Relationship of Surface-tension to the Union of Toxin and Anti-toxin. AMILCARE BERTOLINI (*Biochem. Zeitsch.*, 1910, 28, 60—66).—Traube stated that toxins in opposition to anti-toxins lower the surface-tension, and that the union of toxin and anti-toxin has a still greater effect than the toxin. The present investigations made with diphtheria and tetanus toxin and anti-toxin do not confirm this view. The union has no effect on surface-tension as tested by Traube's stalagmometer.

W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

Apparatus for Collecting and Measuring the Gases Evolved During Fermentation. ARTHUR HARDEN, J. THOMPSON, and WILLIAM J. YOUNG (*Bio.-Chem. J.*, 1910, 5, 230—235).—In measuring the total quantity and rate of evolution of gases evolved during fermentation, it is essential to keep the pressure in the flask as nearly constant as possible throughout the experiments.

Two forms of apparatus devised and used by the authors for this purpose are fully described with diagrams.

W. D. H.

Influence of the Mineral Constituents of Nutritive Solutions on the Development of *Azotobacter*. (Mme.) H. KRZEMIENIEWSKA (*Bul. Acad. Sci. Cracow*, 1910, B, 376—413).—Potassium, calcium, magnesium, phosphorus, and sulphur are all essential to the development of *Azotobacter*. Under the conditions of the experiments, the minimum amounts required for the normal consumption of 1 gram of dextrose were as follows: K, 0·38; Ca, 0·36; Mg, 0·35; P, 2·46; and S, more than 0·49 mg. Deficiency of any essential mineral constituent of the nutritive solution results in the less economical utilisation of the dextrose, and consequently less nitrogen is fixed per gram of dextrose. The organisms leaves off increasing, whilst the respiration of the existing cells goes on.

The addition of potassium, sodium, and magnesium compounds above certain limits acts injuriously on *Azotobacter*. The injurious effect is diminished or prevented by addition of calcium salts. Addition of magnesium salts lessens the injurious action of excessive amounts of potassium and sodium.

N. H. J. M.

Assimilation of Nitrogen by Certain Nitrogen-fixing Bacteria in the Soil. W. B. BOTTOMLEY (*Proc. Roy. Soc.*, 1910, B, 82, 627—629. Compare *ibid.*, 81, 287).—Culture solutions inoculated respectively with pure cultures of *Azotobacter* from garden soil, and *Pseudomonas* from bean and clover nodules and with both organisms together, showed that whilst *Azotobacter* alone fixed 2.19 mg. and *Pseudomonas* alone 2.30 mg. of nitrogen per unit of carbohydrate, the two organisms together fixed 4.51 mg. per unit of carbohydrate.

Further experiments are described in which garden soil (5 oz.), both without and with lime, was inoculated from an extract of soil which had been sterilised and then inoculated with *Azotobacter* and *Pseudomonas* so as to accustom the organisms to soil conditions. In ten days the mixed culture in limed soil gave an increase of 35 mg. of nitrogen, and in the unlined soil an increase of 25 mg. The amount of nitrogen introduced by the culture itself was 6 mg. N. H. J. M.

Some Factors Concerned in the Fixation of Nitrogen by *Azotobacter*. CONRAD HOFFMANN and B. W. HAMMER (*Centr. Bakt. Par.*, 1910, ii, 28, 127—139).—Experiments with a number of different soils showed that their nitrogen-fixing power varied from 0.15 to 14.47 mg. of nitrogen per gram of mannitol consumed.

Mannitol and lactose proved to be the best sugars for maximum fixation in impure cultures, whilst very little fixation was obtained with maltose and sucrose. With pure cultures, mannitol and dextrin gave the best results, and good results were also obtained with sucrose, but not with lactose.

As regards mineral nutrients, di- and tri-calcium phosphates give better results (in impure cultures) than the monocalcium salts.

The period of incubation for impure cultures should be from twenty-one to twenty-eight days. If too prolonged, losses of nitrogen may occur. Calcium carbonate need only be present in very small amounts.

The amount of protein in the cells of *Azotobacter* was found to range from 8.31 to 19.13%, whilst the phosphorus (as P_2O_5) varied from 2.51 to 3.97%. N. H. J. M.

The Products Resulting from the Putrefaction of Fibrin by *Clostridium carnosifetidis*, and the Rauschbrand Bacillus. FRANCIS H. MCCRUDDEN (*J. Biol. Chem.*, 1910, 8, 109—111).—The two micro-organisms mentioned are selected as widely different types of anaerobes. The products of putrefaction of fibrin show distinct differences, Rauschbrand leading, for instance, to the formation of about one-fifteenth of the gases produced by *Clostridium*. The question is to be followed up in the hope that such differences may be of diagnostic value. W. D. H.

Action of Dysentery Bacilli on Nitrites and Nitrates. W. J. LOGIE (*J. Hygiene*, 1910, 10, 143—154).—All the dysentery strains examined with one exception (*B. Neisser*, Ac.) reduced nitrates to nitrites; none which fail to ferment mannitol destroyed nitrites. *B. dysenteriae*, Jürgens, although closely related to *B. dys.*, Flexner, differs from

it in its action on litmus whey, and in failing to destroy nitrite. *B. dys.*, Jürgens, is the only strain found to form indole, and, therefore, to give the cholera-red reaction. The addition of dextrose enables Shiga strains to destroy nitrites. With an abundant supply of oxygen, all the strains fail to destroy nitrites and nitrates, but in media which contain dextrose the inhibitory effect of oxygen is less marked. Under anaërobic conditions, Shiga strains and *B. dys.*, Jürgens, still fail to destroy nitrites.

W. H. D.

The Enzymes in Different Bacteria. EMIL ABDERHÄLDEN, LUDWIG PINCUSOHN, and ADOLF R. WALTHER (*Zeitsch. physiol. Chem.*, 1910, 68, 471—476).—The culture fluids of a paratyphoid-like bacillus and of *Streptococcus pleuro-pneumoniae* have no peptolytic action on various kinds of peptone. *Paratyphus B.* slightly decomposes casein peptone. Various bacilli were grown in different media with and without peptone, and the change in the rotatory power noted. It is hoped that this method, of which a few preliminary examples are given, may be utilised in the differentiation of micro-organisms.

W. D. H.

Amount of Phosphorus in Yeast and in Some Yeast Preparations. EDUARD BUCHNER and HUGO HAEHN (*Biochem. Zeit.*, 1910, 27, 418—426).—Yeast which had been subjected to a pressure of 70 atmospheres was found to contain about two-thirds of the total phosphorus originally present.

Yeast prepared with acetone contains more phosphorus than when acetone and ether are employed. No connexion seems to exist between the fermenting power of yeast and the percentage of phosphorus.

N. J. H. M.

Action of Sodium Selenite on the Production of Carbon Dioxide from Living and Dead Yeast. MARIE KORSKOFF (*Ber. deut. bot. Ges.*, 1910, 28, 334—338).—Whilst a 1% sodium selenite solution completely checks the production of carbon dioxide from zymoin, living yeast produces considerable amounts even in 30% solutions. Small amounts of sodium selenite (0.1—0.5%) even increase the activity of living yeast.

N. H. J. M.

Fermentation of Galactose by Yeast and Yeast Juice. ARTHUR HARDEN and ROLAND V. NORRIS (*Proc. Roy. Soc.*, 1910, B, 82, 643—649).—The results of other investigators showing that some yeasts when cultivated in a medium containing galactose acquire the property of fermenting galactose are confirmed. Yeast trained in this manner yields a juice capable of fermenting galactose.

A fermenting mixture of yeast juice and galactose reacts with phosphate in a manner similar to yeast juice and dextrose. The rate is accelerated; an extra amount of carbon dioxide is evolved, equivalent to the phosphate added, after which the rate again becomes normal. An organic phosphorus compound is produced, which is not precipitated by magnesium citrate mixture. Small amounts of sodium arsenate also accelerate the fermentation of galactose.

N. H. J. M.

Disinfection by Chemical Agencies and Hot Water. HARRIETTE CHICK (*J. Hygiene*, 1910, 10, 237—286).—Further experiments are adduced to show that disinfection is an orderly time process analogous to a chemical reaction between the bacterium and the disinfectant. The destruction of bacteria by water between 45° and 55° is also a consistent time process, and runs parallel to the heat coagulation of proteins; both proceed in accordance with the mass-law and in agreement with the law of Arrhenius in relation to temperature changes. The temperature-coefficient is very high. Disinfection by drying and by sunlight, so far as can be judged by the scanty data at present available, fall into line also. A large number of different micro-organisms were subjected to experiment.

W. D. H.

The Influence of Cell Lipoids on the Autolysis of Wheat Seedlings. MARIE KORSKOFF (*Biochem. Zeitsch.*, 1910, 28, 121—126).—Powdered wheat seedlings were allowed to autolyse, and the amount of proteolysis was estimated; previous extraction of the powder with solvents of lipoids (light petroleum, ether, alcohol, etc.) lessens the amount of autolysis, from which the conclusion is drawn that they have an important influence on the process.

W. D. H.

Rôle of Reduction Processes in the Respiration of Plants. W. ZALESKI (*Ber. deut. bot. Ges.*, 1910, 28, 319—329).—The reducing power of various seeds, as indicated by methylene-blue, was found to be greatest in peas and least in cereals and oil seeds, whilst wheat and lupins occupy an intermediate position. There is a certain parallelism between the anaerobiose and the reducing power of seeds, since the anaerobiose is highest in leguminous seeds and lowest in cereal and oil seeds (Godlewski and Polzeuizsz, *Abstr.*, 1898, ii, 400; 1901, ii, 618).

Acid salts, such as dihydrogen potassium (or sodium) phosphate, depress the reducing power of pea seeds. Neutral salts and sodium selenite and ammonium vanadate act still more unfavourably. Alkalis, and especially dihasic phosphates, stimulate the reduction process.

N. H. J. M.

Action of Salts on the Respiration of Plants and on the Respiration Enzymes. W. ZALESKI and A. REINHARD (*Biochem. Zeitsch.*, 1910, 27, 450—473).—All the salts contained in Knop's nutritive solution depress the energy of respiration. An acid reaction is especially injurious, and alkalis also cause a decrease.

Dibasic phosphates considerably increase the production of carbon dioxide in ground living seeds of *Pisum sativum*, *Zea Mays*, and *Lupinus angustifolius*, and in the seeds frozen and killed with acetone. In the case of *Triticum* the energy of respiration was diminished.

Acid phosphates diminish the production of carbon dioxide. Only basic phosphates have a stimulating effect. Phosphates stimulate not only the zymase, but also the oxydases, catalases, and reductases.

As regards the relative amounts, or the relative activity of the reductase and catalase of different seeds, it was found that the activity

of the reductase increased in the following order: *Zea* (0), *Triticum* (1), *Lupinus* (10), and *Pisum* (480), whilst in the case of catalases the order is reversed: *Pisum* (10), *Lupinus* (12), *Triticum* (30), and *Zea* (50).

N. H. J. M.

Importance of Mucilages in the Germination of Seeds. CIRO RAYENNA and M. ZAMORANI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 247—253).—Linseed which has been deprived of its mucilago by repeated treatment with water yields fewer seedlings than the untreated seed, and their weight and ash are less than that of normal seedlings. When, however, the sand in which germination is effected is treated with a solution containing sugar and the inorganic constituents found in the mucilage extracted, the weight and ash of the seedlings obtained approximate to those of normal seedlings. This tends to show that the mucilage functions as a reserve food material during germination.

R. V. S.

Lecithin and Lecithides in Germinating Seeds. LUIGI BERNARDINI and G. CHIARULLI (*Bied. Zentr.*, 1910, 39, 594—596; from *Staz. sper. agrar. ital.*, 1909, 42, 97).—Seeds of cereals contain both free and combined lecithin in the proportion of about 1:2. During normal germination both forms of lecithin increase, at about the same rate, until the period of chlorophyll production, after which it decreases. In absence of light, germination is accompanied by a loss of lecithin, chiefly of the combined portion.

N. H. J. M.

Occurrence and Detection of Chlorogenic Acid in Plants. Extraction and Yield of Caffeic Acid from Plants. CHARLES CHAUAUX (*J. Pharm. Chim.*, 1910, [vii], 2, 292—298).—From Gortier's results (*Abstr.*, 1908, i, 186, 345) it appears that caffeic acid in plants results from chlorogenic acid, and the author has therefore devised a quantitative method of extracting caffeic acid from plants, and from the results so obtained he proposes to deduce the quantity of chlorogenic acid present, on the assumption that the latter is equivalent to about half its weight of caffeic acid.

The residue left on distilling the solvent from an alcoholic extract of the finely-ground plant is taken up with warm water and this shaken out twice with ether to remove impurities. The filtered aqueous extract is treated with excess of a solution of basic lead acetate, the precipitate collected, washed, and decomposed with cold dilute sulphuric acid in slight excess, giving a solution of impure chlorogenic acid. This is rendered slightly alkaline, boiled for thirty minutes, and excess of dilute sulphuric acid added. The liberated caffeic acid is extracted with ether, purified by re-crystallisation from boiling water, and weighed. In some cases it requires further treatment for the removal of impurities. A number of colour reactions for the detection of chlorogenic acid are given, and a list of plants in which this acid has been found and estimated as caffeic acid by the process outlined above. The quantity of caffeic acid found varied from 0.6 to 10% for different plants.

T. A. H.

Rôle of Catalase in Plants. ANNA ROSENBERG (*Ber. deut. bot. Ges.*, 1910, 23, 280—288).—Results of experiments with a variety of seeds in which equal weights of the powdered substance were digested for an hour with water and treated with hydrogen peroxide indicated that no direct connexion exists between the anaerobiose and the catalase, since the leguminous seeds acted the least on hydrogen peroxide, whilst the cereal seeds, although little suited to anaerobiose, proved to be very rich in catalase.

Acids, even 0.25% citric acid, are very injurious to catalase, and the acid phosphates of sodium and potassium decrease its activity. Alkali salts, such as sodium carbonate and dibasic phosphates, are favourable, the latter acting most in the case of seeds which only contain small amounts of catalase.

The catalase of lupins is rapidly destroyed by autolysis. Addition of dibasic phosphates protects the catalase from decomposition; the amount, however, gradually diminishes when the temperature is raised.

Whilst the amount of catalase increases during germination, addition of potassium nitrate, magnesium sulphate, potassium dihydrogen phosphate, and calcium nitrate respectively (0.5%) was found to retard the production of catalase.

N. H. J. M.

Alkaloidal Content of Cinchona Leaves. P. VAN LEESEN (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 210—227).—The researches of Junghuhn, de Vrij (*Abstr.*, 1897, i, 383), Broughton, Howard and Meens have shown on the whole that cinchona leaves contain alkaloids, although they leave some doubt as to the existence of other than amorphous alkaloids in these plant organs. Lotsy's physiological experiments with cinchona leaves (*Ann. Jard. Bot. Buit.*, 1899, 12, 36) indicated that alkaloids are formed in the leaves, whence they are transported to the stem, where the final formation of crystalline alkaloids occurs, and hence are to be regarded as assimilation products. The present paper disproves Lotsy's contention, and shows that the alkaloids, which include quinine and cinchonine, occurring in the leaves are products of metabolism.

The method of estimating the total alkaloids consisted in mixing the ground leaves or bark with slaked lime, sodium hydroxide and ammonia, and extracting with ether, the alkaloids being recovered from the latter in the usual manner, dissolved in *N*/10-acid, and the excess of acid titrated. The results obtained show (1) that exposure of living leaves to light or dark has no effect on their alkaloidal content; (2) that no evidence could be obtained of the transport of alkaloid through the branches to the stem, and (3) that both the mesophyll and veins of the leaves of *C. Ledgeriana* and *C. succirubra* contain the crystalline alkaloids, quinine and cinchonine. These results are on the whole in harmony with those found for *Datura Stramonium* by Feldhaus (*Abstr.*, 1905, ii, 648), and for tea by Du Pasquier (*Inaug. Diss.*, Zurich, 1908), and by Weevers (*Ann. Jard. Bot. Buit.*, 1904, 21, ii, Part 1), with the exception that Weevers found no caffeine in fallen tea leaves, whilst in the present investi-

gation fallen *cinchona* leaves proved to be as rich in alkaloids as the living leaves.

T. A. H.

The Alkaloid of Pituri Obtained from *Duboisia hopwoodii*. A. C. H. ROTHERA (*Bio.-Chem. J.*, 1910, 5, 193—206).—The alkaloid of pituri is nicotine; no evidence was found of the presence of any other alkaloid.

W. D. H.

Action of Ultra-violet Rays on Plants Yielding Coumarin, and on Plants in which the Odour is due to Decomposable Glucosides. JEAN POUGET (*Compt. rend.*, 1910, 151, 566—569. Compare Heckel, this vol., ii, 63).—An odour of coumarin is rapidly developed when the leaves of plants, such as *Melilotus officinalis* or *Asperula odorata*, are exposed for a short time to the light from a quartz-mercury lamp. The leaves become blackened, owing to the death of the protoplasm; the enzymes survive, however, and effect scission of the glucosides. The action of ultra-violet light in this respect is identical with that of cold and anaesthetics (Grignard, *Abstr.*, 1909, ii, 813; Mirande, *ibid.*, ii, 824).

Similar results have been obtained in experiments on the leaves of the cherry laurel and other plants which develop their characteristic odour on exposure to the rays.

W. O. W.

Effect of Poisonous Solutions Containing Alkaloids on Soils and Plants. RICHARD OTTO and W. D. KOOPER (*Landw. Jahrb.*, 1910, 39, 397—407. Compare *ibid.*, 1896, 25, 1007).—Nicotine solutions (0.3%) are very favourable to the growth of *Nicotiana tabacum*, and favourable to *Solanum tuberosum*. In the case of *Nicotiana* the amount of alkaloid was increased, and similar results were obtained with other nitrogenous substances, such as sodium nitrate. The alkaloid had no appreciable effect on the other constituents.

Nicotine is absorbed physically by humus and sandy soils. It partly decomposes in the soil, with production of ammonia, and a part is lost by volatilisation.

N. H. J. M.

Origin and Physiological Function of Pentosans in Plants. II. LEO RAVENNA and O. MONTANARI (*Atti R. Accad. Lincei*, 1910, [v], 19, i, 202—207. Compare Ravenna and Coeser, *Abstr.*, 1909, ii, 1046).—The results previously described have been confirmed in most respects by further experiments on the leaves of *Vicia faba minor*. The quantity of pentosans present in the leaves showed a tendency to increase during the day and decrease during the night. A considerable increase occurs when the leaves are supplied with carbohydrate food (dextrose, fructose, sucrose), whilst prevention of the function of the chlorophyll in the leaves and the absence of carbohydrate nutriment cause the amount of pentosans to decrease.

R. V. S.

Chemico-physiological Investigations on the Tubercles of *Vicia faba*. GIOVANNI SANA (*Atti R. Accad. Lincei*, 1910, [v], 19, i, 207—211).—In the fresh plant, the bacteroidal tissue of the tubercles was found to contain 0.965% of nitrogen, the cortical layer

only traces. In the roots, 0.2987% of nitrogen was found, in the stems, 0.1635—0.065%, and in the leaves, 0.707—0.7995%. The non-protein nitrogen in the tubercles amounted to 0.033%. Boiling water extracts various amino-acids from the tubercles; among them *L*-asparagine and glycine were identified.

R. V. S.

Metabolism of Moulds. *Aspergillus fumigatus*. I. CRO RAVENNA and G. PROHINI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 312—316).—From alcoholic extracts of three cultures of *A. fumigatus*, the authors isolated the following three substances respectively: (1) a highly toxic substance, forming colourless, prismatic crystals, m. p. about 300°; (2) mannitol; (3) trehalose.

R. V. S.

Behaviour of Moulds Towards the Stereoisomerides of Unsaturated Dibasic Acids. ARTHUR W. DOX (*J. Biol. Chem.*, 1910, 8, 265—267).—Buchner found that *Penicillium glaucum* and *Aspergillus niger* will grow in media containing ammonium salts of fumaric acid. But they were not able similarly to utilise maleic acid as a source of carbon. The latter is not found in nature; nevertheless, the distinction is surprising, because of the readiness with which the two acids are convertible one into the other. The present experiments, made with a large number of moulds, confirm Buchner's statement. Mesaconic and citraconic acids also resemble maleic acid. Itaconic acid gave a slight growth in a few cases, but no normal colony.

W. D. H.

Amylase of Ungerminated Cereals and Malt. T. CHURAZECZ (*Bied. Zentr.*, 1910, 39, 641—642; from *Zeitsch. Spiritusind.*, 1909, 32).—Malt amylase acts most favourably when 1% potato starch is employed with a temperature between 50° and 55°. The amylase of ungerminated cereals shows the same optimal temperatures for saccharification, but is less active than the amylase of malt. The diastatic power of wheat and rye is greater than that of barley, and still greater than that of oats. The assumption that malt has a special amylase, different from the amylase of resting grain, would therefore seem to be incorrect. It is probable that in cereals the action of the amylase is retarded by some unknown factor (amylum-coagulate).

It is suggested that cereal seeds contain an amylase which does not possess the full enzymatic power, a pro-enzyme which changes to active enzyme during germination.

N. H. J. M.

Composition of Barbados Rain. R. RADCLIFFE HALL and J. R. BOVELL (*Rep. Agric. Work, Barbados; Imp. Dept. Agric. West Indies for 1907-1909*, 3. Compare Brünnich, this vol., ii, 647).—Analyses of fortnightly samples of rain-water from December, 1907, to May, 1909. The average amounts of nitrogen as ammonia and as nitrates in the rain of 1908, and the total amounts per acre, were as follows:

| Rainfall, inches. | Nitrogen per million | | Nitrogen per acre (lb.) | | | Per cent. of Total N. | |
|----------------------|----------------------|-----------------|-------------------------|-----------------|--------|-----------------------|-----------------|
| | as Ammonia. | as Nitrates. | as Ammonia. | as Nitrates. | Total. | as Ammonia. | as Nitrates. |
| 40.28 | 0.032 | 0.334 | 0.295 | 3.498 | 3.793 | 7.8 | 92.2 |

The chlorine in the rain-water amounted to 8.38 per million, corresponding with 76.39 lb. per acre. N. H. J. M.

Analytical Chemistry.

A New Indicator for Alkalimetry and Acidimetry. 6-Sulpho- β -naphthol-1-azo-*m*-hydroxybenzoic Acid. R. MELLER (*Chem. Zeit.*, 1910, 34, 1073—1074).—When 4-amino-3-hydroxybenzoic acid is diazotised and combined with β -naphthol-6-sulphonic acid, a soluble dye is obtained, which may be used as an indicator.

The sodium salt forms dark violet crystals, dissolving readily in water to a violet solution. The acid is also soluble, and forms deep red solutions. Alkalis change the colour to violet, but an excess of alkali causes a change to cherry-red; the indicator is therefore unsuitable for use on test-papers. The indicator is prepared by adding *N*/10-hydrochloric acid to a 1% solution of the sodium salt until the colour is distinctly red. Such a solution is three times as strongly coloured as one of litmus of equal concentration. In *N*/100-solutions of acids or alkalis, the sensitiveness is equal to that of phenolphthalein. C. H. D.

Chart Presentation of Recent Work on Indicators. GEORGE S. WALPOLE (*Bio.-Chem. J.*, 1910, 5, 207—214. Compare this vol., i, 541).—The apparatus previously described is explained more fully, the new method of notation of hydrogen-ion concentration explained, and a diagram is given of how Sørensen's results can be conveniently displayed on a chart. A few examples illustrate how the chart may be used. W. D. H.

Apparatus for Measuring Known Quantities of Liquids. F. HUDIG and M. J. VAN'T KRUYSS (*Chem. Weekblad*, 1910, 7, 179—182).—Six vertical tubes closed by stopcocks at the lower end are sealed at their upper ends into a tube slightly inclined to the horizontal, connected at one end through a stopcock to a water pump, and at the other (lower) through a long vertical tube to the vessel containing the liquid to be measured. A short glass tube sealed into the main tube, and closed with rubber tube and a pinchcock, serves to admit air to the apparatus at will. The liquid is drawn up into the horizontal tube by the water pump, and flows into the vertical stopcock tubes. Definite volumes are marked on these tubes, and can be measured off. The apparatus is specially adapted to the measurement of given volumes of strong acids. A. J. W.

Quantitative Spectral Analysis. WALTHER HEMPEL and ALFRED L. VON KLEMPERER (*Zeitsch. angew. Chem.*, 1910, 23, 1756—1759).—An arrangement is described by means of which certain metals can be quantitatively estimated by spectroscopic observations. The spectroscope is focussed on a oxyhydrogen flame.

supplied with hydrogen and oxygen at constant pressure, and the metals are introduced into the flame by allowing the gases, evolved from an acidified solution of the metal by an electric current of constant strength, to mix with the entering hydrogen. The concentration of the solution under examination is diminished until the characteristic lines of the particular metal just cease to be recognisable in the spectroscope.

From comparative observations under exactly similar circumstances with a standard solution, the concentration of the metal in a solution of unknown strength can be obtained. The method can be applied to the estimation of potassium, lithium, calcium, and thallium, and is recommended for the estimation of the two former in samples of soil. It is shown that the presence of small quantities of other flame-colouring metals is without much influence on the results obtained. Larger quantities lead to an apparent diminution in the quantity of the metal under examination.

H. M. D.

Volumetric Method of Estimating Iodide in Presence of Chloride, Bromide, or Free Iodine. WILLIAM C. BEAY and G. M. J. MACKEY (*J. Amer. Chem. Soc.*, 1910, 32, 1193-1204).—A method of estimating iodides in aqueous solution is described which is based on that suggested by Sammet (*Abstr.*, 1906, ii, 153), and depends on the oxidation of the iodide by potassium permanganate, the removal of the liberated iodine with carbon tetrachloride, and its subsequent titration with standard sodium thiosulphate. Experiments have been made with potassium iodide solutions of known strength, which show that the results obtained by this method are accurate within 0.1%, and are independent of the presence of chlorides, bromides, or copper sulphate. When free iodine is present in the solution to be analysed, it is estimated by direct titration with sodium thiosulphate; the amount of iodine present as iodide is then ascertained by subtracting this quantity from the total iodine.

The estimation may be carried out by titrating the solution directly with potassium permanganate in presence of carbon tetrachloride, since, as the concentration of the potassium iodide is decreased, a larger proportion of the iodine is dissolved by the carbon tetrachloride, until finally the aqueous liquid becomes colourless. It has been found, however, that this method is not entirely satisfactory, since the reduction of the permanganate to the manganous salt is not quite complete, and an error amounting to about 0.4-0.5% of the permanganate solution is thus introduced.

E. G.

Estimation of Fluorine in Aromatic Fluorine Derivatives HANS MEYER and ALFRED HUB (*Monatsh.*, 1910, 31, 933-938).—See this vol., i, 735.

An Ozonometer. STEPHAN JAHN (*Ber.*, 1910, 43, 2319-2321).—The ozonometer consists essentially of a U-tube fitted with stop cocks, one of these being a three-way one, and connecting with a manometer containing paraffin oil. The U-tube is 2 cm. in diameter, and has an internal volume of about 70 c.c.; sealed into it, and running

through its length, is a thin platinum wire, which can be heated by an electric current.

To use the instrument, 150—200 c.c. of the gaseous mixture containing ozone are passed through the U-tube, which is then closed at the inlet. The three-way tap is turned to connect with the manometer, and the liquid in the latter adjusted to a zero mark. The platinum wire is then heated to a dull red heat for five to ten seconds, this time being sufficient to destroy the ozone. When the original temperature has been attained, the manometer is again adjusted to zero, and the increase of pressure determined, from which the percentage of ozone can be calculated. A correction has to be applied for the amount of ozone decomposed while the gas is in contact with the cold platinum wire before the latter is heated. This is determined by a blank experiment.

The method is more exact and quicker than the determination of ozone with potassium iodide.

T. S. P.

The Quantitative Analysis of Some Inorganic Sulphur Acids. ANGELO CASOLARI (*Gazzetta*, 1910, 40, ii, 22—27).—A polythionate containing m atoms of sulphur in the molecule yields $m-1$ molecules of sulphuric acid when treated with hydrogen peroxide and sodium or potassium hydroxide (Abstr., 1908, ii, 222). The solution to be titrated is therefore rendered perfectly neutral, and treated with a pure neutralised solution of hydrogen peroxide and a known volume of $N/10$ -alkali hydroxide. After heating on the water-bath, the excess of alkali is titrated with acid: $\text{Na}_2\text{S}_m\text{O}_6 + (3m-5)\text{H}_2\text{O}_2 + (m-1)\text{H}_2\text{O} = \text{Na}_2\text{SO}_4 + (m-1)\text{H}_2\text{SO}_4 + (3m-5)\text{H}_2\text{O}$. The same reaction may be used for thiosulphates: $\text{Na}_2\text{S}_2\text{O}_3 + 4\text{H}_2\text{O}_2 + \text{H}_2\text{O} = \text{Na}_2\text{SO}_4 + \text{H}_2\text{SO}_4 + 4\text{H}_2\text{O}$. Under the same conditions, thiocyanates are decomposed into a sulphate and a cyanate: $\text{KSCN} + 4\text{H}_2\text{O}_2 + 2\text{KOH} = \text{K}_2\text{SO}_4 + \text{KCNO} + 5\text{H}_2\text{O}$. A volume of $N/10$ -sulphuric acid equal to that of the alkali taken is then added, and, after boiling for a few minutes, the acidity of the solution is determined. If ammonium thiocyanate is present, the ammonia must be expelled by boiling with alkali before oxidising.

When a thiosulphate and a thiocyanate are both present in the solution, the sum of the two may be estimated as above, and the thiosulphate estimated separately by means of iodine.

C. H. D.

Detection of Nitrogen in Organic Substances. H. RUSSELL ELMS (*Chem. News*, 1910, 102, 187).—The test described by Castellana (Abstr., 1905, ii, 201) is untrustworthy, owing to the fact that cyanide is formed when powdered magnesium and sodium or potassium carbonate are heated together in a limited supply of air, the nitrogen necessary to the formation of cyanide being obtained from the atmosphere. When, however, the reaction is allowed to proceed rapidly in a copious supply of air, cyanide is not formed. Similar reactions take place when mixtures consisting of magnesium and either calcium carbonate, barium carbonate, or strontium carbonate are heated in contact with a small amount of air; in these cases, cyanide, cyanamide, nitride, and carbide are formed.

W. P. S.

Estimation of Ammonia Nitrogen in Water in Presence of Hydrogen Sulphide. EDWARD BARTOW and B. H. HARRISON (*J. Amer. Chem. Soc.*, 1910, 32, 1256—1259).—The presence of hydrogen sulphide in a water interferes with the Nessler test. When a large amount of ammonia is present, the hydrogen sulphide may be removed by precipitation with a salt of zinc or lead, and the ammonia can then be estimated directly by the Nessler reagent. If, however, the quantity of ammonia is small, and it is desirable to distil and test the distillates, the results obtained are inaccurate. It has been found that accurate results can be obtained by the following method. To 500 c.c. of the water, a measured quantity of *N*-sulphuric acid is added, and 100 c.c. are distilled; by this means the hydrogen sulphide is completely removed. A volume of *N*-sodium hydroxide equal to that of the sulphuric acid used is now added, the water is again distilled until 200 c.c. have collected, and the Nessler test is applied to the distillate. E. G.

Estimation of Small Quantities of Nitrogen by Pelouze's Reaction. A. T. DAVENPORT (*J. Amer. Chem. Soc.*, 1910, 32, 1237—1241).—A method is described for estimating small quantities of nitrogen occurring in the form of nitrates by Pelouze's reaction, which consists in the oxidation of ferrous chloride in presence of hydrochloric acid. A diagram of the apparatus is given.

The most important features of this method are the measurement of the volume of gas over sodium hydroxide solution in a jacketed burette, graduated to 1/20 c.c., as in the Schultze-Tiemann method, and the correction of the volume by comparison with a standard volume contained in another burette under exactly the same conditions. The process is simple and easily manipulated, permits of an estimation being carried out in ten minutes, and gives accurate results. E. G.

Easy Detection of Arsenic; Rapid Separation of Arsenic and Some Other Metals from Liquids. C. E. CARLSON (*Zeitsch. physiol. Chem.*, 1910, 68, 243—262).—On adding hydrogen sulphide to an acid solution of arsenious acid, or thioacetic acid to a solution of arsenic acid, arsenious sulphide is precipitated, but if the amount is only a fraction of a mg., the separation takes a long time. If, however, ether is added, or preferably a mixture of ether and chloroform, and the whole well shaken, the ethereal layer contains all the arsenious sulphide in suspension or in pseudo-solution. Addition of alcohol promotes the separation. On being evaporated on the water-bath, arsenious sulphide is left, which may then be further identified by the mirror test. When testing urine (or other organic liquid), this is evaporated to dryness and the residue is distilled with hydrochloric acid and some ferric chloride; the distillate is diluted with solution of hydrogen sulphide and shaken with ether. The quantitative process is, briefly, as follows: The ethereal residue is heated with 1 c.c. of 30% sulphuric acid and 2 c.c. of 5% potassium permanganate for ten to fifteen minutes. The arsenic acid formed is reduced to the arsenious state by heating for half an hour at 50—70° with addition of 10 c.c. of strong solution of sulphur dioxide, and the

solution is finally evaporated nearly to dryness. Another 5 c.c. of sulphur dioxide are added, and the evaporation is repeated. The residue is now dissolved in 15 c.c. of water, 2 grams of sodium hydrogen carbonate are added, and the arsenic is titrated with *N*/100-iodine with starch as indicator.

Other sulphides, such as those of lead and mercury, are also taken up readily by ether.

L. DE K.

Estimation of Potassium by the Cobaltinitrite Method. L. T. BOWSER (*J. Ind. and Eng. Chem.*, 1909, 1, 791—798).—A detailed account of the methods employed, and the results obtained by previous workers, those of Drushel and of Adie and Wood being fully discussed, and stated to be unsatisfactory in several ways when repeated by the author, who suggests the following modifications. The potash is brought into solution, any excess of acid driven off, and the residue boiled with sodium carbonate to remove any interfering metals, the filtrate concentrated, acidified with acetic acid, and the potassium precipitated with excess of the reagent according to the equation:

This precipitate can be boiled with sodium hydroxide, the precipitated cobalt hydroxide, $\text{Co}(\text{OH})_2$, separated, and the filtrate and washings titrated with potassium permanganate, the reaction being:

or the precipitate can be treated directly with potassium permanganate, when a more complicated reaction occurs, owing to trivalent cobalt being reduced to bivalent, and thereby releasing one atom of oxygen, which oxidises some of the precipitate:

Likewise, the di-potassium-sodium-cobaltinitrite may be collected on asbestos, oxidised by hot standard potassium permanganate, which is decolorised by an excess of standard oxalic acid, and then titrated back with permanganate.

The influences exerted on the reaction by (1) varying the concentrations of the solutions; (2) the presence of other salts, and (3) the acid with which the potassium is combined are also investigated, and the results tabulated.

F. M. G. M.

Rapid Estimation of Copper, Silver, Cadmium, and Bismuth by means of the Mercury Cathode and Stationary Anode. RAYMOND C. BENNER (*J. Amer. Chem. Soc.*, 1910, 32, 1231—1237).—Stoddard (Abstr., 1909, ii, 347) has described a method of electroanalysis by means of a mercury cathode and a stationary platinum gauze anode, in which the evolution of the gas by the current causes sufficient agitation of the liquid to enable the metals to be deposited in an adherent form. This method has now been applied to the estimation of copper, silver, cadmium, and bismuth. The apparatus is as simple as any other form of electrolytic apparatus employed for the purpose, the metal is deposited nearly as rapidly as by the rotating anode and mercury cathode, and the results are as accurate as those obtained by other methods in which mercury is used as the cathode.

The precipitation is complete in twenty minutes with copper, ten minutes with silver and cadmium, and twenty-five minutes with bismuth.

E. G.

Volumetric Estimation of Mercury by means of Ammonia. G. BRESSANIN (*Boll. chim. farm.*, 1910, 49, 589—591 *).—Archetti's method, based on the estimation of the acid liberated according to the equation $\text{HgCl}_2 + \text{NH}_3 = \text{NH}_2\text{HgCl} + \text{HCl}$, only gives quantitative results when four times the molecular quantity of ammonia is taken for the reaction, the excess being afterwards estimated by titration with litmus.

R. V. S.

Estimation of Indium with the Use of a Mercury Cathode. LILY G. KOLLOCK and EDGAR F. SMITH (*J. Amer. Chem. Soc.*, 1910, 32, 1248—1250).—It has been found that the indium in a solution of indium sulphate containing a little free acid can be satisfactorily estimated electrolytically with the use of a rotating mercury cathode. When 10 c.c. of the solution containing about 0.10 gram of metal were used, with a current of 2—4 amperes, an *E.M.F.* of 6.5—7.5 volts, and an anode rotating 750 times per minute, the precipitation was complete in fifteen minutes. Estimations were also made by using a platinum cathode and a rotating platinum spiral anode; in presence of 0.1 c.c. of concentrated sulphuric acid and a few drops of gelatin, an adherent deposit of indium was obtained in twenty-five minutes. A potassium cyanide electrolyte and one containing Rochelle salt also proved satisfactory.

E. G.

Volumetric Method for the Estimation of Manganese. FLOYD J. METZGER and ROBERT F. McCRACKAN (*J. Amer. Chem. Soc.*, 1910, 32, 1250—1251).—Metzger and Heidelberger (this vol., ii, 658) have stated that when a solution of manganese in sulphuric acid is treated with sodium bismuthate, it is oxidised to the quadrivalent state. A method has now been devised for estimating manganese by means of this reaction.

Fifty c.c. of a standard manganese solution are treated with 10—15 c.c. of concentrated sulphuric acid, 1—2 grams of finely-powdered sodium bismuthate are added to the cooled liquid, and the mixture is heated in a water-bath until the basic bismuth compound subsides in a granular form. The flask is cooled, a known excess of ferrous sulphate solution is added, the liquid is diluted to about 200 c.c., and titrated back with standard potassium permanganate. The value of the permanganate in terms of iron multiplied by 0.4918 gives the value in terms of manganese.

The method is rapid, and the end-point is sharp and distinct. It is being applied to the analysis of *spiegel* and manganese ores. E. G.

Estimation of Manganese in Potable Water. J. RODENBERG (*Chem. Weekblad*, 1910, 7, 877—879).—As the tint of the solution of permanganate obtained in the estimation of manganese in potable water by the persulphate method usually differs from that of the colorimetric standard made from potassium permanganate, the author employs as standard one or more c.c. of a solution of manganese

* and *Ann. Chim. anal.*, 1910, 15, 413—419.

ammonium sulphate containing 0.0025 gram Mn_2O_3 per litre, this solution being oxidised with persulphate in the same way as the sample under investigation. This difference of tint being due to chlorides in the sample, they must be eliminated. The author's procedure is as follows: 50 c.c. of the sample are boiled for several minutes with 5 c.c. of 50% nitric acid, a slight excess of silver nitrate solution added, and then 10 c.c. of a 10% solution of ammonium persulphate. The solution is brought to the boiling point, cooled, and compared with the standard tint. The method will show the presence of 0.025 mg. of Mn_2O_3 .

A. J. W.

Detection of Small Quantities of Manganese in Foode. DUMITRESCU and E. NICOLAU (*Ann. Falsif.*, 1910, 3, 370—372).—The material is incinerated, the ash is treated with nitric acid, evaporated to dryness, the residue is dissolved in water, and the solution is filtered. A portion of the filtrate is then mixed with an equal volume of a 40% ammonium persulphate solution, 1 drop of a 2% cobalt nitrate solution is added, and the mixture is heated to boiling. Should manganese be present, a pink coloration develops, due to the formation of permanganate. The authors have detected the presence of manganese in such substances as flesh, brain, hilec, peas, beans, lentils, cereals, plums, eggs, milk, wine, etc., by means of this test.

W. P. S.

Error in Permanganate Titrations. WILLIAM C. BRAY (*J. Amer. Chem. Soc.*, 1910, 32, 1204—1207).—It has been shown by Bray and MacKay (this vol, ii, 996) that when an iodide is titrated directly with potassium permanganate, the latter is not completely reduced to the manganous state and an error results, amounting to about 0.10 c.c. of a 0.12N-permanganate solution. It is evident therefore that the reduction of the permanganate takes place in stages, and it is probable that a similar error may occur in other cases of titration with this salt. Škrabal (Abstr., 1908, ii, 17) has shown that the reduction from the manganic to the manganous state by oxalic acid is a slow reaction, and that a stable complex is formed between the manganic salt and the oxalic acid.

Experiments have therefore been made to ascertain the conditions in which the error due to incomplete reduction of permanganate is appreciable in oxalic acid titrations, and it has been found that the error varies from 0.01 to 0.14 c.c. of a 0.12N-permanganate solution, and is negligible if the acid is present in only small amount and the final temperature is 70—80°.

An investigation is being carried out with the object of determining whether there is an appreciable error in the titration of ferrous sulphate solutions with permanganate.

E. G.

The Determination of Iron and Aluminium in Inorganic Plant Constituents. R. F. HARE (*J. Ind. and Eng. Chem.*, 1910, 2, 27—28).—The estimation of iron and aluminium in the presence of manganese, calcium, magnesium, and phosphoric acid is a difficult one, and no satisfactory process has been suggested previously.

A solution of, and representing one gram of, the ash is treated with more than sufficient pure ferric chloride to combine with all the phosphoric acid; sodium carbonate is added until a permanent precipitate is just formed, which is then redissolved with 1 c.c. of 80% acetic acid, and the solution boiled for three or four minutes and rapidly filtered; the precipitate is dissolved in hydrochloric acid, and the iron and aluminium reprecipitated with ammonium hydroxide, dried, ignited, and weighed; this weight, minus the phosphoric acid and ferric oxide (found by other methods) and the ferric oxide added, will give the weight of aluminium oxide in the ash. A great deal depends on the proper adjustment of the amounts of sodium carbonate and of acetic acid added, an excess of either causing serious error. The addition of ferric chloride gives a more easily filtered and washed precipitate, and ensures complete precipitation of phosphoric acid.

The iron is determined in a fresh solution of the ash by the Zimmermann-Reinhardt method, the ferric iron being instantly reduced with stannous chloride, and titrated with potassium permanganate in the presence of hydrochloric acid after the addition of a "titrating solution" of manganese sulphate, phosphoric and sulphuric acids.

This method is claimed to be more accurate and rapid than when zinc is employed for the reduction of the ferric salt. F. M. G. M.

Estimation of Ferrous Oxide in Silicates. MAX DITTRICH and A. LEONHARD (*Ber. Vers. Oberrheinisch. Geol. Ver.*, 1910, ii, 92—93).—The process usually employed is that recommended by Pebel-Döller, consisting in heating the silicate with a mixture of sulphuric and hydrofluoric acid in an atmosphere of carbon dioxide. The solution is then titrated with permanganate as usual.

The authors, however, state that if the silicate contains manganese also, the titration proceeds in an irregular manner, and the results become untrustworthy. This may be prevented by adding to the acid mixture 1—2 grams of potassium sulphate; the titration will then proceed normally. L. DE K.

Ammonium Perchlorate as a Reagent. Metalamines Perchlorates. ROBERTO SALVADORI (*Gazzetta*, 1910, 40, ii, 19—21).—Perchlorates of the metallic amines are obtained by adding a 20% solution of ammonium perchlorate in ammonia, D 0.90, to ammoniacal solutions of metallic salts. Precipitation is complete in the case of cobalt, nickel, manganese, and cadmium, even in dilute solutions. Zinc is incompletely precipitated, and copper only slowly from very concentrated solutions. The mercury precipitate is soluble in an excess of the reagent. The method may be used for the separation of cadmium from the sulphides of the second group. The sulphides are dissolved in nitric acid, excess of ammonia is added, and the bismuth is removed by filtration. The ammoniacal solution of ammonium perchlorate is added to the filtrate, and the cadmium is immediately precipitated, carrying with it a small quantity of copper.

The reagent may also be used to separate a cobalt salt from a cobalt-amine salt. In presence of an excess of ammonium perchlorate, and out of contact with air, cobalt is completely precipitated as the compound

$\text{Co}(\text{ClO}_4)_2 \cdot 6\text{NH}_3$, the cobaltammine remaining in solution (compare this vol., ii, 959).

The cadmium and zinc compounds form white crystals,

and $\text{Zn}(\text{ClO}_4)_2 \cdot 4\text{NH}_3$ stable at 100° , melting at about 220° , and decomposing rapidly at 250° . They explode by percussion or if heated rapidly.

C. H. D.

Detection of Small Quantities of Nickel. ALBERTO BIANCHI and ETTORE DI NOLA (*Boll. chim. farm.*, 1910, 49, 517—520).—Nickel-plating may be recognised without damage to the object by moistening it with a drop of acid, which is then absorbed by blotting paper or allowed to fall on to a porcelain surface, rendered alkaline with ammonia, acidified with acetic acid, and tested with dimethylglyoxime. In the presence of acetic acid there is no possibility that the red coloration will be masked by other coloured substances (cupric hydroxide, ferric hydroxide).

R. V. S.

Estimation of Tin in Presence of Antimony. JEAN A. SANCHEZ (*Bull. Soc. chim.*, 1910, [iv], 7, 890—894).—The process depends on the fact that whilst ferric chloride is reduced quantitatively by stannous chloride, it is unaffected by antimonous chloride.

In the case of a simple mixture of the two chlorides, the solution is titrated with a standard ferric chloride solution in presence of hydrochloric acid, the formation of a permanent greenish-yellow coloration being taken as the end-point. Where both substances must be estimated, they are converted into their sulphides in the usual manner, and the mixture of sulphides treated with hydrochloric acid and potassium chlorate. To this solution aluminium is added, and when the reduction is completed, the antimony is filtered off and the filtrate and washings diluted to a known volume with diluted hydrochloric acid (50%) and titrated with a ferric chloride solution, which has been standardised against a solution of stannous chloride containing the equivalent of 1% of tin. The precipitated antimony is dissolved by means of hydrochloric acid and iodine solution, and estimated as the sulphide. 0.1 Gram of tin in presence of 1.1 gram of antimony can be estimated accurately by this method.

T. A. H.

Analysis of Tin-Antimony Alloys. LEROY W. MCCAY (*J. Amer. Chem. Soc.*, 1910, 32, 1241—1248).—It has been shown in an earlier paper (*Abstr.*, 1909, ii, 351) that the separation of tin and antimony can be effected by taking advantage of the fact that when a dilute solution of hydrofluoric acid, containing tin in the stannic condition and antimony in the antimonious state, is treated with hydrogen sulphide, only the antimony is precipitated.

The following method is recommended for the analysis of alloys of tin and antimony. From 0.5 to 1 gram of the alloy in the form of filings or fine borings is heated rapidly with concentrated sulphuric acid in a quartz or porcelain dish until fumes of sulphuric anhydride begin to escape, and the heating is then continued for half an hour. If the liquid is now clear and the residue, consisting of lead sulphate, is

quite white, the dish is cooled and its contents are transferred to a 250 c.c. platinum dish containing 5 c.c. of hydrofluoric acid (18%) and 20 c.c. of water. The solution is heated until it boils, and is then diluted to 150 c.c., and 50 c.c. of 95% alcohol are added. When the lead sulphate has subsided, it is collected, washed with water containing one-fourth of its volume of alcohol and a little sulphuric acid, and is dried, ignited, and weighed. The filtrate is collected in a large platinum dish, diluted to about 450 c.c., and treated with a rapid current of hydrogen sulphide for an hour. The precipitate is collected, washed with a saturated solution of hydrogen sulphide containing acetic acid, and afterwards digested repeatedly with colourless sodium sulphide solution. The cupric sulphide, which is left after this treatment, is dissolved in nitric acid, and the copper estimated electrolytically. The sodium sulphide solution is acidified with sulphuric acid, and the antimony precipitate is converted into the black anhydrous sulphide. The tin in the filtrate from the copper and antimony sulphides may be estimated by evaporating the liquid and subsequently heating it until sulphuric anhydride fumes are evolved, and precipitating the tin as stannic acid by pouring the sulphuric acid solution into an excess of water. E. G.

Separation of Bismuth from Alloys containing also Lead and Tin. CHARLES E. SWETT (*J. Ind. and Eng. Chem.*, 1910, 2, 28).—The following expedient is suggested as a means of overcoming the difficulties usually experienced in this estimation. The nitric acid filtrate from the stannic oxide is treated with a moderate excess of potassium or sodium hydroxide, which precipitates bismuth and cadmium, if present, and redissolves the lead hydroxide. The hydroxides are collected, washed, and redissolved in hydrochloric acid, the bismuth being then separated as oxychloride by pouring into a large quantity of water. F. M. G. M.

Rapid Methods for the Analysis of Water. ARISTIDE DAMÉ (*Chem. Zeit.*, 1910, 34, 1057—1058).—In order to ascertain whether a water is suitable for drinking, the author recommends that the following estimations be made: The calcium and magnesium present may be estimated volumetrically, the former by the titration of its oxalate, after this has been precipitated and separated in the usual way, and the latter by precipitating it as ammonium magnesium phosphate and titrating this salt with a uranium solution. Sulphates are titrated with barium chloride solution, and the total carbon dioxide is titrated with barium hydroxide-sucrose solution, allowance being made for the alkalinity of the water. Nitrites are estimated colorimetrically by means of the indole reaction, and the proportion of organic matters is estimated by heating the water with permanganate solution in the presence of sodium carbonate. The organic matters may also be estimated by titration according to Deniges' cyanide-silver nitrate method. Should further information be required as to the quality of the water, the ammonia, chlorides, nitrates, etc., may be estimated, the usual methods being employed for the purpose.

In addition, tests may be applied for the detection of *Eacterium coli*. W. P. S.

Acid Content of Moor Water. KURD ENDELL (*J. pr. Chem.*, 1910, [ii], 82, 414—422).—The acidity of moor water has been determined by direct titration with *N*/100-potassium hydroxide. The method of adding standard barium hydroxide and titrating the excess does not give trustworthy results, the titre decreasing with time, probably owing to the action of the alkali on humus substances present as sols. Before titration, it is necessary to dialyse the water in order to get rid of humus substances. The moor water of the red and of the black moors of the Rhone are 0.007 normal. The water of the Paulsborner moor is 0.0063 normal, the acidity being due entirely to carbonic acid.
C. S.

Estimation of Butyl and Amyl Alcohols in Alcoholic Liquids. A. LASSERRE (*Ann. Chim. anal.*, 1910, 15, 338—341).—Instead of estimating the total quantity of higher alcohols in alcoholic liquids as is done in the Allen-Marquardt process, the method described by the author limits the estimation to that of butyl and amyl alcohols; propyl alcohol is eliminated by treating the alcoholic liquid with carbon disulphide, which extracts the butyl and amyl alcohols. After oxidation, the butyric and valeric acids are extracted from the solution by means of benzene, and their quantity estimated by titration. The details of the process are as follows: 100 c.c. of the alcoholic liquid, 70 c.c. of carbon disulphide, and 450 c.c. of saturated sodium chloride solution are placed in a separating funnel, and after the addition of a quantity of water sufficient to redissolve the precipitated sodium chloride, the mixture is shaken for five minutes. The carbon disulphide is then separated, and the extraction is twice repeated, the united carbon disulphide extracts being next shaken three successive times with moderately concentrated sulphuric acid. The sulphuric acid extract is now heated to 60° in order to remove any traces of carbon disulphide, then diluted with 20 c.c. of hot water, and 5 grams of potassium dichromate and 1 c.c. of concentrated sulphuric acid are added. The whole mixture is then heated in a closed flask for one hour at 50°, cooled, and diluted to a volume of 100 c.c. Twenty-five c.c. of this solution are shaken for three minutes with 30 c.c. of benzene, the latter is separated, filtered, mixed with an equal volume of alcohol, and the solution is titrated with *N*/20-alcoholic potassium hydroxide solution, using phenolphthalein as indicator. The quantity of alkali used in the titration may be calculated into amyl alcohol, but the result obtained must be multiplied by 2.082, this being the ratio of the total amount of the acids present to that portion which is obtained by one extraction with benzene. A method has been described previously (*Abstr.*, 1907, ii, 991) for the separate estimation of butyric and valeric acids.
W. P. S.

Physico-chemical Estimation of the Ash of Wine. HENRI PELLET (*Ann. Chim. anal.*, 1910, 15, 385).—It is pointed out that the conductivity process described by Dutoit and Dubouix (this vol., ii, 552) has already been applied to the estimation of mineral matters in various substances; twenty years ago, Reichert employed the method for the estimation of ash in sugars, etc., but the results

obtained were unsatisfactory. More recently, Main, in a paper submitted to the Seventh International Congress of Applied Chemistry, London, 1909, gave the details of procedure necessary for the correct estimation of ash in sugar syrups by this process. W. P. S.

Polarimetric Estimation of Sucrose in Presence of Reducing Sugars. P. LEMELAND (*J. Pharm. Chim.*, 1910, [vii], 2, 298—302*.)—The method is based on the observation made by Cross, Bevan, and Smith (*Trans.*, 1898, 73, 463) that hydrogen peroxide destroys the optical activity of reducing sugars, forming products eventually identified by Morrell and Crofts as osones (*ibid.*, 1899, 75, 786). The author finds that lactose and dextrose are attacked by hydrogen peroxide in presence of manganese dioxide, forming optically inactive products, whilst sucrose remains unaffected. If, therefore, the optical activity of a solution containing one of these sugars and sucrose is known, the amount of sucrose can be estimated by a determination of the optical activity after the effect of the reducing sugar has been eliminated. Where a small quantity of sucrose occurs with much dextrose, the latter may be almost completely separated by treatment with alcohol of 91° (Lindet, *Abstr.*, 1894, ii, 64), and the part soluble in alcohol may then be recovered and treated as described above.

This method is not applicable where sucrose occurs with maltose. Details of the method of working are given in the original.

T. A. H.

Detection of Inositol as a means of Identifying Wine Vinegar. P. FLEURY (*J. Pharm. Chim.*, 1910, [vii], 2, 264—266).—A number of samples of genuine wine vinegar examined by the author all contained distinct quantities of inositol; the detection of inositol is, therefore, considered to be of use in determining the genuineness of a sample of wine vinegar. If inositol is not present, the sample is probably prepared from alcohol and not from wine. The method described previously by Meillere and Fleury (this vol., ii, 553) may be employed for detecting the inositol. W. P. S.

Estimation of Formaldehyde. WALTER BRÄUTIGAM (*Pharm. Zentr.-h.*, 1910, 51, 915—916).—The process described depends on the decomposition of formaldehyde by calcium hypochlorite; calcium carbonate is formed, and its quantity is a measure of the amount of formaldehyde present. The reaction proceeds according to the equations: $\text{CH}_2\text{O} + \text{CaOCl}_2 = \text{HCO}_2\text{H} + \text{CaCl}_2$; $\text{HCO}_2\text{H} + \text{CaOCl}_2 = \text{CO}_2 + \text{H}_2\text{O} + \text{CaCl}_2$; and $2\text{CaOCl}_2 + \text{CO}_2 + \text{H}_2\text{O} = \text{CaCO}_3 + \text{CaCl}_2 + 2\text{HClO}$. One molecule of formaldehyde therefore yields one molecule of calcium carbonate. In carrying out the estimation, a definite volume of the formaldehyde solution is mixed in a flask with an excess of freshly prepared calcium hypochlorite solution, and the mixture is placed aside for some hours at the ordinary temperature. The clear supernatant liquid is then passed through a weighed filter, and the filtrate is heated almost to boiling in order to ascertain whether all the

* and *Ann. Chim. anal.*, 1910, 15, 415—419.

formaldehyde has been decomposed; should such be the case, the solution remains clear, but if a further quantity of calcium carbonate forms it must be collected on the filter together with the main bulk of the precipitate. The precipitate and filter are washed until free from chlorides, dried at 100° , and weighed.

W. P. S.

Estimation of Formic Acid in the Presence of Acetic Acid. II. DELEHAYE (*Ann. Falsif.*, 1910, 3, 386—388).—The method proposed depends on the reduction of mercuric sulphate to insoluble mercurous sulphate. A quantity of the solution under examination, containing not more than 0.2 gram of formic acid, is mixed with 50 c.c. of mercuric sulphate solution (prepared as described below) and boiled under a reflux apparatus for forty-five minutes. The mixture is then cooled rapidly, the liquid is decanted through a weighed filter, and the volume of the filtrate is measured; the precipitate is then rinsed on to the filter with the aid of a saturated mercurous sulphate solution, washed with 50% alcohol, dried at 110° , and weighed. To the weight found is added a quantity in the proportion of 0.20 gram for every 100 c.c. of the filtrate; the weight thus corrected is then multiplied by 0.0927 to obtain the amount of the formic acid. The mercuric sulphate solution employed is prepared by mixing 10 grams of mercuric oxide with 20 c.c. of hot water, adding sulphuric acid until the oxide has dissolved, and diluting the mixture to a volume of 250 c.c. The filtrate obtained in the estimation should measure not less than 100 c.c., and the filtration must be carried out immediately the mixture has been cooled in order to prevent contamination of the mercurous sulphate with mercuric sulphate, which is liable to crystallise out subsequently.

W. P. S.

The Separation and Estimation of Aspartic and Glutamic Acids. THOMAS B. OSBORNE and LEONARD M. LIDDLE (*Amer. J. Physiol.*, 1910, 23, 420—425).—Aspartic and glutamic acids react acid to litmus, but their acid sodium salts do not. By Fischer's method of protein analysis, glutamic hydrochloride is usually contaminated with leucine hydrochloride, and the two cannot be separated by direct crystallisation. When, however, the solution is made neutral to litmus, leucine crystallises out readily, and from the mother liquor it is possible to separate out a further large amount of glutamic hydrochloride. It was found possible to effect a fairly satisfactory separation of leucine and aspartic acid by taking out a small fraction of the esters after most of the leucine had distilled over and before the aspartic ester begins to distil freely, and then treating this separately by a method described with detail in the text.

W. D. H.

Methods for the Detection and Volumetric and Gravimetric Estimation of Salicylic Acid in Wines, and its Detection in Cases of Poisoning. GIUSEPPE CATTINI (*Boll. chim. farm.*, 1910, 49, 641—649).—For the detection of salicylic acid in wine, urine, and other coloured organic products, acidification and subsequent extraction with toluene are recommended, this solvent being preferable to ether because it does not remove colouring matter from the aqueous liquid.

Various methods which have been proposed for the estimation of salicylic acid are shown to be inaccurate.

R. V. S.

Estimation of Fat in Flesh. G. DIESSSELHORST (*Pflüger's Archiv*, 1910, 134, 496—500).—The fat extracted from flesh or tissue by Dormeyer's process (digestion with pepsin, extraction of the digest with ether, and weighing the ethereal extract) is very impure, and, consequently, the results yielded by the method are untrustworthy. It is shown that if the dry powder is first extracted with ether in a mill, as described by Lehmann and Völtz (*Abstr.*, 1903, ii, 702), the fat obtained has the chemical and physical properties of beef fat. When the extracted residue of flesh is subjected to further treatment by Dormeyer's process, an additional small quantity of "fat" is obtained, which is largely contaminated with substances other than beef fat.

W. P. S.

Estimation of Coconut Oil in Admixture with Butter Fat. NOEL C. CASSAL and B. HENRY GERRANS (*Chem. News*, 1910, 102, 190—191).—In the process described, the fatty acids obtained from the fat are subjected to a somewhat prolonged distillation with steam at a high temperature in order to increase the difference between the titration number of the insoluble volatile fatty acids from coconut oil and the titration number of the insoluble volatile fatty acids from butter fat. The process is as follows: 3 grams of the fat are saponified by heating with 10 c.c. of alcohol and 2 c.c. of 50% sodium hydroxide solution; after the alcohol has been removed by evaporation, the residual soap is dissolved in 50 c.c. of boiling water, 10 c.c. of concentrated hydrochloric acid are added, and then 50 grams of anhydrous calcium chloride. The flask is now connected with a condenser and heated by means of a calcium chloride bath, b. p. 141—116°, and when the contents of the flask begin to boil, steam is admitted and the distillation is continued until 500 c.c. of distillate have been collected. The distillate is filtered as it distils over, and the filtrate is collected in a 500 c.c. flask. At the end of the distillation, the condenser tube and the fatty acids on the filter are washed with cold water to remove hydrochloric acid and soluble fatty acids, the insoluble fatty acids are then dissolved from the condenser tube and the filter by means of hot alcohol, and the solution is titrated with *N*/10-barium hydroxide solution. In the case of coconut oil, the insoluble volatile fatty acids require 66 c.c. of *N*/10-alkali for neutralisation, whilst those from butter fat require 16 c.c.

W. P. S.

Alkylamines as Products of the Kjeldahl Digestion. C. G. ERDMANN (*J. Biol. Chem.*, 8, 41—55).—Compounds containing the groups =NMe , =NHMe , or NMe_2 can yield mono-, di-, or tri-methylamine on digestion with sulphuric acid and a catalyst. The separation of organic base from ammonia in the Kjeldahl distillate is effected by adding to the neutralised solution 5—10 c.c. of an alkaline mixture containing 20% of sodium hydroxide and 30% of sodium carbonate, and 0.1 gram of yellow mercuric oxide for every c.c. of *N*/10-base present. After shaking for one hour in the dark, and keeping till the mercury

has settled, an aliquot part of the supernatant liquid is distilled. The ammonia is retained by the mercuric oxide, and the organic base which distils is titrated. The ammonia is then estimated by difference.

The author suggests that the method can be used as a general qualitative method for determining in nitrogeous substances the presence of alkylamine groups, and can probably also be used for approximately quantitative determinations as well. G. S. W.

Vortmann's Nitroprusside Reaction for Hydrogen Cyanide. H. J. VAN GIFFEN (*Pharm. Weekblad*, 1910, 47, 1043).—A modification of Vortmann's process for the detection of hydrogen cyanide. Although not quite so delicate as the original method, it has the advantage of not being interfered with by the presence of alcohol.

To a portion of the distillate are added a few pieces of sodium nitrite and then 2 or 3 drops of officinal ferric chloride solution. To the brownish-yellow liquid is then added dilute sulphuric acid drop by drop, when effervescence takes place and the liquid turns bright yellow. After heating to boiling, the iron is precipitated by adding excess of ammonia, and the filtrate is evaporated to dryness on the water-bath. The residue is dissolved in a little water, and the solution cooled in ice. On adding a drop of dilute ammonium sulphide, a violet colour is formed, which, according to the amount of cyanide present, more or less rapidly passes into blue, green, and yellow. L. DE K.

Estimation of Nitrogen Existing as Cyanamide and as Dicyanodiamide in Calcium Cyanamide. ALBERT STUTZER and J. SÖLLI (*Zeitsch. angew. Chem.*, 1910, 23, 1873—1874).—An extract of calcium cyanamide is first prepared by shaking the substance (10 grams) with 400—450 c.c. of water for two and a-half hours in a rotary apparatus. The flask is then filled to the mark (500 c.c.) and the contents filtered.

The nitrogen in the form of cyanamide is estimated in 25 c.c. (= 0.5 gram of substance) by adding 10 c.c. of silver acetate solution (prepared by adding 400 c.c. of 10% ammonia to 100 grams of silver acetate and diluting to 1 litre). The precipitate is collected on a nitrogen-free filter, and after all the solution has run through and the beaker below the filter has been changed, is washed with water, and the nitrogen determined by the Kjeldahl method.

The nitrogen as dicyanodiamide is estimated in the undiluted filtrate from silver cyanamide (25 c.c. = 0.357 gram of original substance) by adding 10 c.c. of 10% potassium hydroxide solution, and estimating the nitrogen in the precipitated silver dicyanodiamide.

In directly estimating the dicyanodiamide, an alcoholic extract is made by shaking the substance (10 grams) for an hour with 250 c.c. of 94% alcohol. A portion of the filtered extract (100 c.c.) is evaporated to dryness, dissolved in hot water, treated with 10 c.c. of the silver acetate solution, filtered, and the precipitate washed. The filtrate is then mixed with 10 c.c. of 10% potassium hydroxide, at once filtered, and then estimated by Kjeldahl's method.

N. H. J. M.

Calcium Cyanamide; its Analysis and the Changes in Composition it Undergoes when Exposed to the Atmosphere. CH. BRIOUX (*Ann. Chim. anal.*, 1910, 15, 341-346).—Calcium cyanamide gradually undergoes decomposition when exposed to moist air, the calcium being converted into calcium hydroxide and carbonate, and cyanamide is liberated; the latter polymerises to form a double molecule, dicyanodiamide. All these changes proceed more rapidly when the air contains carbon dioxide and is saturated with moisture; under these conditions, as much as 80% of the soluble nitrogenous compounds present in calcium cyanamide may be converted into dicyanodiamide in the course of a few months. As dicyanodiamide has toxic properties and is injurious to vegetation, it is of some importance to know to what extent the decomposition has proceeded in any sample of calcium cyanamide which has been stored in sacks or bags. This may be ascertained by estimating the cyanamide and dicyanodiamide present in a solution of the calcium cyanamide, and the process recommended for the purpose depends on the fact that cyanamide yields a precipitate with silver nitrate which is insoluble in excess of ammonia, whilst the analogous precipitate obtained in the case of dicyanodiamide is soluble in ammonia; further, both substances are precipitated by silver nitrate in the presence of potassium hydroxide. One gram of the calcium cyanamide is shaken with 250 c.c. of water for three hours, and the solution is then filtered; 100 c.c. of the filtrate are now treated with 20 c.c. of 5% silver nitrate solution, and an excess of ammonia is added. The precipitate is collected on a filter, washed first with dilute ammonia, then with water, and is next dissolved in warm dilute nitric acid (a small quantity of black residue sometimes remains insoluble), and the amount of silver thus obtained in solution is titrated with $N/10$ -ammonium thiocyanate solution; each c.c. of the latter solution is equivalent to 0.0014 gram of nitrogen. A second quantity of 100 c.c. of the filtrate is then treated with silver nitrate solution in the presence of an excess of potassium hydroxide; the precipitate formed is collected, and the nitrogen in it is estimated by Kjeldahl's method. The difference between the amounts of nitrogen found in the two estimations gives the nitrogen present in the form of dicyanodiamide.
W. P. S.

Estimation of Digitoxin in Foxglove Leaves and their Preparations. JAMES BURMANN (*Bull. Soc. chim.*, 1910, [iv], 7, 973-982).—It is now known that the three chief glucosides of foxglove leaves are digitoxin, digitalin, and digitonin, of which the first is of primary physiological importance and is the one usually estimated for medical purposes. Koller's method of estimation (*Abstr.*, 1898, ii, 267, 657) is that generally used, and a comparison has therefore been made between the amorphous digitoxin (ψ -digitoxin) isolated by this method of estimation and (a) crystalline digitoxin and (b) Cloetta's soluble digitoxin (digalene of commerce).

The results show that ψ -digitoxin and Cloetta's soluble digitoxin are both amorphous and are practically identical in melting point, solubility, and physiological activity, and that both are less active than crystalline digitoxin and show quite different physical constants.

Keller's process can only be regarded as useful in estimating the medicinal value of the drug and its preparations if it is admitted that in the product weighed there is a constant relation between the digitoxin and the other glucosides present.

T. A. H.

Estimation of Adrenaline in Normal Blood and after its Injection by means of Physiological Methods. PAUL TRENDLENBURG (*Arch. exp. Path. Pharm.*, 1910, 63, 171—176).—See this vol., ii, 971.

Estimation of Caffeine in Roasted Coffee. C. VIRCHOW (*Chem. Zeit.*, 1910, 34, 1037—1038).—Twenty grams of ground coffee are moistened with about 10 c.c. of water, and the mass is introduced into a shaking cylinder furnished with a stopcock and ground stopper. One hundred c.c. of chloroform are added, and the whole is well shaken for a minute. The chloroform is drawn off, and the extraction is repeated twice. To the united filtrate is added 1 gram of paraffin, and the chloroform is recovered by distillation. To the residue in the flask are then added 25 c.c. of hot water, the liquid is poured into a beaker, and the flask rinsed twice with 25 c.c. of hot water. The mixture is well stirred, then allowed to cool, and filtered; no caffeine is retained by the paraffin. On evaporating the aqueous solution, crude caffeine is left, which may be weighed. It is then purified by re-dissolving it in water, and again evaporating to dryness with addition of a little magnesium oxide and extracting the mass thrice with chloroform; on evaporating this, almost pure caffeine is left, but it is advisable by way of a check to ascertain its nitrogen content by means of a Kjeldahl estimation.

L. DE K.

Toxicological Detection of Colchicine. HERMANN FÜHNER (*Arch. exp. Path. Pharm.*, 1910, 63, 357—373).—Colchicine can in forensic cases be detected with certainty by a combination of chemical and biological tests. A slight modification is proposed in Zeisel's test. 1 mg. kills a white mouse. In frogs the toxicity of colchicine is increased 500-fold by warming them to 30—32°, and immunity can be produced in the usual way. In frogs, if the drug is introduced under the skin, it in part re-appears in the urine.

W. D. H.

Estimation of "Saccharin" in Urine. W. R. BLOOR (*J. Biol. Chem.*, 1910, 8, 227—232).—Methods previously proposed for the estimation of "saccharin" in the urine after its administration are not sufficiently exact when dealing with small quantities. The new method proposed is colorimetric and gives good results; the colour is due to the transformation of "saccharin" into what is probably benolsulphonaphthalein (sulphurein) by treatment with a phenol-sulphuric acid mixture, and is a bright yellow in weakly acid solutions, and purple-red in alkali. The purple fades after a time, but the yellow remains unchanged for a month or more. The test is performed with a benzene extract of the urine.

W. D. H.

Estimation of "Saccharin" in Urine and Fæces. ALFRED J. FAREMAN (*J. Biol. Chem.*, 1910, 8, 233—236).—The method is

practically the same as Bloor's (see preceding abstract), but differs in the apparatus used, in the employment of ethyl acetate instead of benzene as solvent, and in one or two other minor points. W. D. H.

Amylases. I. Examination of Methods for Determination of Diastatic Power. HENRY C. SHERMAN, E. C. KENDALL, and E. D. CLARK (*J. Amer. Chem. Soc.*, 1910, 32, 1073—1086).—A critical study of some of the methods in use for measuring diastatic power, carried out mainly on taka-diastase and pancreatin. The Lintner method is said to be insufficiently accurate for preparations of high diastatic power. A modified form of the iodine method is described, by means of which satisfactory results were obtained with taka-diastase, but not with pancreatin. Methods depending on the action of the latter enzyme on pure starch in pure water were found to be useless, because such a medium is too poor in electrolytes for the diastase to function normally. The optimum conditions necessary for the amylase to behave normally have been worked out and incorporated in a new gravimetric, copper-reduction method, which is described in detail. With commercial pancreatin this process gave results twenty times as high as when no electrolyte had been added. W. O. W.

Reaction Distinguishing between the Organic Derivatives of Arsenious Acid and Those of Arsenic Acid. ERCOLE COPELLI (*Boll. chim. farm.*, 1910, 49, 50—51. Compare Abstr., 1909, ii, 830).—The difference in stability towards reducing agents in alkaline solution which is shown by the above acids is shared by their organic derivatives. Atoxyl is reduced by nascent hydrogen in acid solution, giving a yellow precipitate, whilst in alkaline solution it is not attacked. The corresponding arsenious derivative, $\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_2 \cdot 2\text{H}_2\text{O}$, m. p. 90° , is prepared by treating atoxyl with sulphur dioxide in the cold, and precipitating with sodium carbonate. It is reduced by nascent hydrogen in alkaline solution (aluminium and potassium hydroxide), giving a yellowish-white precipitate, and also in acid solution, with formation of a sulphur-yellow precipitate. Methylarsinic acid, which is reducible in acid, but not in alkaline solution, yields when treated with sulphur dioxide a liquid which, when reduced with potassium hydroxide and aluminium, gives a yellow precipitate and blackens a test-paper impregnated with ammoniacal silver nitrate. R. V. S.

Characteristic Reactions of Atoxyl. QUINTO FIORI (*Boll. chim. farm.*, 1910, 49, 98—99).—Atoxyl yields an orange-red coloration with a solution of bleaching powder in the cold. Sodium methylarsinate and sodium cacodylate do not give this reaction, whilst antifebrin gives an olive-green coloration only when warmed. Mercuric chloride produces in solutions of atoxyl a white precipitate, which is soluble in dilute hydrochloric acid and in ammonia. Sodium methylarsinate gives with the same reagent a brick-red precipitate, which is also soluble in hydrochloric acid or ammonia, whilst acetaldehyde and the cacodylate yield no precipitate. The presence of arsenic in atoxyl can be shown readily after a preliminary fusion with sodium hydroxide. R. V. S.

General and Physical Chemistry.

Influence of Temperature on the Refractive Index of White of Egg. AMEDEO HERLITZKA (*Zeitsch. Chem. Ind., Kolloide*, 1910, 7, 251—256).—Previous observations relating to the influence of salts on the refractive index of egg-albumin are referred to. Contrary to the conclusions drawn by Frei (this vol., ii, 365), the author's data indicate that dissolved salts have no influence on the refractive index of colloids.

New measurements of the refractive indices of a series of solutions of egg-albumin have been made at temperatures between 7° and 47°. Whereas Frei's data led him to conclude that the refractive index of colloids varies with the temperature according to a linear equation, the author finds that a quadratic equation of the form $N_t = N_0(1 - K_1t - K_2t^2)$ is necessary for the representation of the temperature influence.

Anomalous Dispersion of Light in an Aqueous Solution of Neodymium Nitrate. L. ISAKOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 236—243 [Physical Part]).—Some preliminary experiments on the dispersion of neodymium nitrate by the interference method. A figure of the apparatus and a table and curves of the results obtained are given. The experimental results agree well with those calculated from the dispersion formula deduced.

Z. K.

Distribution of Chemical Elements in the Earth's Crust. VLADIMIR J. VERNADSKY (*Bull. Acad. Sci. St. Petersburg*, 1910, [vi], 129—1148).—The spectra of a large number of minerals have been investigated in the oxygen gas flame, and the results are given in series of tables showing which elements are present, numerous notes being added regarding the origin, nature, and so forth of the minerals and elements dealt with.

Indium, thallium, rubidium, caesium, gallium, and boron have been found for the first time in several minerals. In some natural glasses, bismuth, copper, and lead have been identified.

When the spectrum of indium is obtained by sparking a solution of a salt or a mineral containing the metal, the platinum wire continues to give the indium spectrum even after being repeatedly washed; the same phenomenon occurs with lithium; in the latter case it sometimes happens that a platinum wire which has ceased giving the lithium spectrum when dipped in pure water or acid, suddenly recommences to give the spectrum; this may possibly be due to the formation of some compound of lithium and platinum. Various methods of determining the spectra of elements are discussed.

Z. K.

Ultra-red Line Spectra. III. Accurate Measurement of Wave-lengths greater than 27,000 Å.-U. FRIEDRICH PASCHEN (*Ann. Physik*, 1910, [iv], 33, 717—738. Compare Abstr., 1909, ii, 630).—The experimental arrangement is described by means of which measurements of the wave-lengths of lines in the ultra-red spectra of lithium, sodium, potassium, rubidium, caesium, and thallium have been made. Observations relating to the ultra-red spectra of cadmium, aluminium, silver, helium, and mercury are also recorded. A special form of iron-constantan thermo-element suitable for use in such measurements is described.

H. M. D.

Ultra-red Line Spectra. (Spectra of Silver, Copper, Caesium, Rubidium, Strontium, Barium.) H. M. RANDALL (*Ann. Physik*, 1910, [iv], 33, 739—746. Compare preceding abstract).—Wave-length measurements in the ultra-red spectra between 8000 and 30,000 Å.-U. are recorded. The grating spectro-bolometer designed by Paschen was employed.

H. M. D.

Relative Duration of Spectral Rays Emitted by Magnesium Vapour in the Electric Spark. GUSTAVE A. HEMSALECH (*Compt. rend.*, 1910, 151, 668—671).—Kayser and Runge's series of nebular lines, in the magnesium spectrum, as well as Rydberg's series of nebular lines, have been studied by the method previously described (*Compt. rend.*, 1905, 141, 1227; 1910, 150, 1743). The relative intensity of the lines is given in tabular form, together with their relative duration at two capacities. The lines of the nebular series are the more sensitive to changes in capacity. The presence of impurities in the magnesium electrodes was rendered evident by the abnormal duration of the foreign lines. The method may be of value in detecting unknown impurities in analysis.

W. O. W.

Spectra of Anode Rays. OTTO REICHENHEIM (*Ann. Physik*, 1910, [iv], 33, 747—762).—Spectral observations have been made of the anode rays which are emitted by salts of the alkali and alkaline-earth metals. In the case of the alkali metals the spectra show lines of the principal and first subsidiary series, but no lines belonging to the second subsidiary series could be detected, even on the plates which were obtained with the longest possible exposure. In general, the anode ray spectra resemble the arc spectra so far as the relative intensity of the individual lines is concerned.

The anode ray spectra of the alkaline-earth elements are much simpler than the corresponding arc spectra. The spectra of all three metals are of the same type, and consist of a series of pairs of lines having the same difference in frequency, and, further, of a single line which bears no obvious relationship to the other lines. The isolated lines in the case of calcium and strontium are the flame spectrum lines, $\lambda = 4227$ and $\lambda = 4608$ respectively. On the other hand, the isolated line found in the case of barium is $\lambda = 6142$, whereas the flame spectrum line is $\lambda = 5536$.

The lines in the anode ray spectra were found to exhibit the Doppler effect, and the magnitude of this was measured in several cases. The various observations are discussed with reference to the

question of what are the carriers of the negative electrons which are responsible for the line spectra. The author considers that the carriers in the case of both the principal and subsidiary series of lines are positively charged ions in accordance with Stark's theory.

H. M. D.

Absorption and Inversion Phenomena in Luminous Hydrogen. AL. PFLÜGER (*Ber. Deut. physikal. Ges.*, 1910, 12, 719—724).—Polemical against Ladenburg (this vol., ii, 811). The results of the author's previous work are summarised. H. M. D.

Absorption Spectra of Sulphur Vapour at Different Temperatures and Pressures, and their Relation to the Molecular Complexity of this Element. J. IVON GRAHAM (*Proc. Roy. Soc.*, 1910, A, 84, 311—324).—The absorption spectra of sulphur vapour have been photographed at temperatures varying from 530° to 900°, and at pressures ranging from atmospheric down to 10 mm. of mercury. The records obtained at constant pressure over the above interval of temperature show that two distinct absorption spectra are present, and these are attributed to the molecular complexes S_8 and S_2 . The various photographs obtained at constant temperature and different pressures indicate that above 580° the S_8 molecules dissociate directly into the diatomic molecules, whereas at or below 520° dissociation takes place with the formation of molecules which are intermediate in complexity. The wave-lengths and frequencies of the bands which are due to the S_8 and S_2 molecules are tabulated.

The conclusions thus arrived at on the basis of spectroscopic evidence are in agreement with the views expressed by Preuner in explanation of the course of dissociation of sulphur vapour at 445°. H. M. D.

Absorption Spectra and Constitution of Benzene Derivatives. I. NICOLAI A. WALLASCHKO (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 751—805).—Curves and tables are given of measurements made of the absorption spectra of *o*-, *p*-, and *m*-hydroxy-, methoxy- and acetoxy-benzaldehydes, phenol, and benzaldehyde in aqueous and alcoholic solutions of various concentrations, and with and without the addition of hydrochloric acid; also for the sodium bisulphite derivatives of benzaldehyde, for anisole, acetoxyphenol, resorcinol monomethyl ether, guaiacol in alcoholic or aqueous solution, mixtures of benzaldehyde and some of its derivatives with chloroform, and for various mixtures of benzaldehyde and guaiacol in alcoholic solution. The results are discussed in detail.

All the ortho- and meta-derivatives give absorption spectra curves of the same type as benzaldehyde, the only difference between the various spectra being that some of the bands in some compounds are more developed than in others. The meta-spectra are intermediate between those of benzaldehyde and the corresponding ortho-compound, and are more readily changed by the addition of hydrochloric acid to the alcoholic solution, the effect being to make the spectra approach nearer to that of phenol. The reason for this is the formation of the unstable compound, $OH \cdot C_6H_4 \cdot CHCl \cdot OH$, which becomes hydrolysed on greater dilution. In water, this compound is

completely hydrolysed, consequently the addition of hydrochloric acid to an aqueous solution of the compounds has no effect. (On the other hand, the ortho-benzaldehyde derivatives in aqueous solution are similarly affected by the addition of sodium hydrogen sulphite, and the greater the concentration of the latter, the more do their spectra approach that of phenol.

The *p*-hydroxy- and -methoxy-derivatives in acid and neutral alcoholic or aqueous and in chloroform solution give curves of the same type as phenol, but the spectra of the *p*-acetoxy-derivative is more like that of *o*-hydroxybenzaldehyde.

The introduction of the benzaldehyde group into the benzene ring induces a definite new state of the latter, and this effect is strengthened by the introduction in the ortho- or meta-position of an acetoxy-, methoxy- or hydroxy-group; these groups are, therefore, regarded as auxo- or batho-chromes, the influence of which on the spectra is to move the absorption bands from the violet towards the red end of the spectrum. A similar effect is produced by the acetylation of benzaldehyde in the para-position, the effect being the same as the acetylation of phenol, which greatly decreases the influence of the hydroxyl group on the benzene ring, but the hydroxy- or methoxy-group in the para-position decreases greatly the influence of the aldehyde group on the benzene ring, but has no influence on the hydroxyl group in phenol, consequently the spectra differs little from that of the latter. The absorption spectrum of a mixture of benzaldehyde and phenol in equimolecular proportions is very much like that of *p*-acetoxybenzaldehyde. A study of the complex curves obtained by mixtures of substances leads the author to reject Baly and Collie's explanation (Trans., 1905, 87, 1332) of the benzaldehyde spectrum. On the contrary it is maintained that benzaldehyde has a greater selective absorption than phenol, and that the entrance of the aldehyde group does not retard the internal motion of the benzene, but induces a new form of vibration. The general results and conclusions drawn from the study of complex absorption spectra agree with those of Hartley (Trans., 1909, 95, 52). Z. K.

Progressive Phosphorescence at a Low Temperature. JOSEPH DE KOWALSKI (*Compt. rend.*, 1910, 151, 810—812).—The fluorescence of some aromatic compounds in alcoholic solution has been examined at different temperatures between -100° and -190° . At about -135° the solutions were viscous, the fluorescence extended towards the red, and was apparent even when not visible at the ordinary temperature. In the case of phenanthrene, anthracene, and others, the fluorescence terminated in the ultra-red. Fluorescence was observed below -135° , when the solutions solidified, whilst at -150° to -165° phosphorescence also appeared, the duration of the latter increasing as the temperature was lowered. A progressive phosphorescence was also observed, having an emission spectrum characteristic for the substance in solution, but independent of the temperature. The bands of which it was composed were more intense and persistent than the broad bands due to ordinary phosphorescence, which disappears as soon as the light exciting it is removed.

For each substance there was a definite temperature above which progressive phosphorescence did not appear. This temperature limit appears to be independent of the freezing point or electrical conductivity of the solution. Phenanthrene does not show the phenomenon above -158° .

W. O. W.

Rotation Dispersion. II. HERMANN GROSSMANN and BERNHARD LANDAU (*Zeitsch. physikal. Chem.*, 1910, 75, 129—218. Compare Abstr., 1909, ii, 713; this vol., ii, 563).—The optical rotation of methyl *l*-malate in over ninety solvents in different dilutions has been measured at 20° for red, yellow, green, light blue, dark blue, and violet light by the method already described (*loc. cit.*), and a number of measurements have also been made with ethyl *d*-tartrate. Methyl malate is specially advantageous for such measurements, owing to the fact that the dispersion curve of the pure liquid is normal, as the following figures show:

| Light. | Red. | Yellow. | Green. | Light blue. | Dark blue. | Violet. |
|-------------------|-------|---------|--------|-------------|------------|---------|
| $[\alpha]_D^{20}$ | -5.62 | -6.42 | -7.57 | -8.96 | -9.49 | -9.83 |

The dispersion curve of methyl tartrate is abnormal. For full details as to the magnitude and sign of the rotation in the different solvents in varying dilutions, the original paper must be consulted.

The more important general conclusions with reference to the action on methyl malate are as follows. In organic solvents containing halogens (over thirty such solvents were used) there is a tendency to reverse the direction of the rotation. This tendency attains its maximum when there are four chlorine atoms in the molecule; it is less when five chlorine atoms are present. Bromal, chloral, and acetyl chloride have an effect different from that of the other halogen compounds, which is accounted for by the fact that the solutions show mutarotation. Further, in most cases the rotation attains a maximum in these solvents and then diminishes somewhat, and the final value is attained only after four or five days. Somewhat similar results are obtained with ethyl tartrate. Heat is developed when the esters are dissolved in the above three solvents, so that the mutarotation is doubtless connected with chemical combination, but this does not account for the maxima.

The effect of solvents containing a hydroxyl (including carboxyl) or nitro-group is similar to those containing halogens, but solvents containing a free amino-group or a nitrogen in the ring of a heterocyclic compound markedly increase the levorotation of the ester. That the effect just described is due to these groups is supported by the observation that when the hydroxyl or amino-group is modified by putting in alkyl or other groups, the influence on the rotation is lessened or non-existent. The methyl group, as shown by observations with hydrocarbons and fatty acids, also has a tendency to reverse the sign of the rotation. Solutions in formic acid showed mutarotation, and detailed observations on this phenomenon were made. In contrast to other groups, the aldehyde group in aliphatic compounds markedly increases the levorotation of the ester. The same group in aromatic compounds has a similar but less pronounced influence.

As regards isomeric compounds, examples are given where a group in the meta-position has a greater influence on the rotation than when in the ortho-position. The difference in the effect of a group when in the nucleus and side-chain was analogous in all cases; the effect is greater in the latter position.

As inorganic solvents, water, sulphuric acid, arsenic trichloride, phosphorus trichloride, and phosphoryl chloride were used, and measurements with both active esters were made. Water has very little effect on the specific rotation of methyl malate. The two halogen compounds of phosphorus cause rotation to the left with both esters. Methyl malate shows mutarotation in phosphoryl chloride, but ethyl tartrate does not. Of all the solvents examined, arsenic trichloride has the greatest effect in reversing the rotation. In the violet, the specific rotation of ethyl tartrate is -39.64 , of methyl malate $+29.68$. In sulphuric acid the natural rotation of the esters is considerably increased.

The observations show that anomalous rotation dispersion is by no means a rare phenomenon; it occurs in each case where the solvent has a tendency to reverse the direction of rotation of the solute.

The influence of concentration on rotation is also discussed. G. S.

Measurement of the Rotation Dispersion of Optically Active Compounds by means of the Nernst Light. HERMANN GROSSMANN and BERNHARD LANDAU (*Zeitsch. Ver. deut. Zuckerind.*, 1910, 1109—1117).—The use of a Nernst lamp in combination with suitable light filters is recommended for the measurement of rotation dispersion. The rotation produced by a 1-millimetre quartz plate has been determined for the approximately monochromatic light which is obtained by use of the coloured solutions suggested as filters by Landolt and by Winther. The specific rotations of dimethyl *l*-malate and diethyl *d*-tartrate for the various coloured rays are recorded, and diagrams are given showing the influence of the solvent on the rotation dispersion of these substances in solution (see preceding abstract). H. M. D.

Liquids with Conical Focal Lines. GEORGES FRIEDEL and F. GRANDJEAN (*Compt. rend.*, 1910, 151, 762—765. Compare this vol., ii, 803).—A geometrical description and discussion of the appearances presented by anisotropic liquids of the type of ethyl azoxybenzoate when these are viewed between crossed nicols under the microscope.

W. O. W.

Triboluminescence. WLADIMIR I. VERNADSKY (*Bull. Acad. Sci. St. Petersburg*, 1910, [vi], 1037—1041).—The property of triboluminescence of substances is closely associated with their electric properties; thus where triboluminescence occurs in substances having a centre of symmetry, pyroelectric and other electric properties also occur. Triboluminescence is a surface phenomenon, and temporary triboluminescence is due to the change in the physical properties of the surface of the crystal. Z. K.

The Nature of Triboluminescence. IWAN VON OSTROMISLENSKY (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 591—606. Compare preceding abstract).—A large number of substances, chiefly organic compounds, investigated by the author and others are tabulated with respect to their triboluminescence, and the following conclusions are drawn. If one member of a group of chemical compounds which form solid solutions with one another, or with some common substance, is permanently triboluminescent, then all the other members will be permanently triboluminescent.

An apparent exception occurs in a group of substances forming solid solutions with dibenzyl, but the latter is shown to occur in two modifications, of which the β -modification and the substances forming solutions with it are not luminescent. A permanently triboluminescent crystal does not give solid solutions with non-luminescent substances, and if one component of a solid solution is triboluminescent, then the solution is likewise triboluminescent.

The triboluminescence of a substance depends only on the system and structure of its crystals; it depends on its chemical constitution only so far as the latter influences crystalline form. Racemic mixtures of triboluminescent substances are always non-luminescent; apparent exceptions are probably not racemates, but only physical mixtures of the two compounds, or they may be cases of temporary luminescence; on the other hand, optically inactive compounds of such type as mesotartaric acid may be triboluminescent.

Only substances the crystals of which have no centre of symmetry can possess the property of permanent triboluminescence. Exceptions to this rule observed by Vernadsky and others are either cases of temporary luminescence (for in some cases the decay of this property may take a very long time), or the crystalline form of the substance in question has not yet been accurately determined. Thus at 130°, potassium nitrate, which at that temperature exists as hexagonal crystals of the rhombohedral class, is permanently triboluminescent, but at the ordinary temperature, when the crystals belong to the rhombic system of the holohedral class, they are only triboluminescent when freshly prepared. There is also reason to think that the intensity of triboluminescence depends on the system and class to which the crystals of a substance belong.

Z. K.

Triboluminescence of Racemic Compounds. IWAN VON OSTROMISLENSKY (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 607—609. Compare preceding abstract).—The fact that racemic compounds are never triboluminescent can be used as a very rapid, simple method of distinguishing between the racemate and the mere mixture of two optically active compounds, and also to ascertain the exact point at which a racemate is resolved into its constituents and vice versa. This method may also be employed to determine exactly when one non-triboluminescent modification of a substance passes into a new crystalline, triboluminescent modification.

Z. K.

Triboluminescence of Minerals. B. A. LINDNER (*Bull. Acad. Sci. St. Petersburg*, 1910, [vi], 999—1022).—A historical résumé of

the previous work done on the subject. The triboluminescence of various natural minerals has been examined, and the minerals are classified with respect to this property and their chemical constitution. The following conclusions are drawn: (1) Triboluminescence in organic substances is of frequent occurrence. (2) Whereas the triboluminescence of artificial crystals is sometimes only temporary, that of the natural crystals is constant, and does not depend on the time. (3) Minerals belonging to the most varied chemical classes and groups can show the property, but with few exceptions either all or none of the members of an isomorphous series are triboluminescent. (4) The hardness of a mineral exercises no influence, but the more brittle and the more marked the cleavage the more intense is the luminescence. (5) All triboluminescent minerals are non-conductors of electricity, and all those that have pyroelectric properties are also triboluminescent. The character of the luminescent sparks is the same for all minerals. (6) The triboluminescence does not depend on the character and temperature of the medium surrounding the mineral. After reviewing the various theories advanced to explain triboluminescence, the author draws the conclusion that the most applicable is Vernadsky's (*Bull. Acad. Sci. St. Petersburg*, 1906, 49), namely, that the triboluminescence of chemical compounds is closely dependent on their crystalline form. So far as is at present known, the crystalline form of nearly all triboluminescent substances belongs to the class in which there is no centre of symmetry. Z. K.

Oxidation of Hydrogen Iodide under the Influence of Light. B. S. SCHWEZOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 219 [Physical Part]).—The purpose of the research was the construction of a chemical photometer. The oxidising action of sulphuric, hydrochloric, and nitric acid on potassium iodide in diffused sunlight was investigated in a special apparatus, of which a figure is given. A constant current of air passing through the mixture kept the concentration of oxygen in it constant. Nitric acid reacts rapidly even in the dark; sulphuric and hydrochloric acid react much more slowly, and with about the same velocity. The order of reaction, calculated by the formula

$$n = (\log Q - \log Q_2) / (\log C_1 - \log C_2)$$

(Q and Q_2 = concentration of the separated iodine; C_1 and C_2 the concentration of potassium iodide) is 2 for dilute solution, and 2.25 for concentrated solutions (compare Plotkinoff, *Abstr.*, 1907, ii, 212; 1908, ii, 790). Equivalent quantities of sodium, potassium, and cadmium iodide under similar conditions evolve equal quantities of iodine. Z. K.

Chemical Changes Produced by Different Kinds of Rays
IV. Catalytic Action of Sunlight in the Presence of Inorganic Substances. CARL NEUBERG (*Biochem. Zeitsch.*, 1910, 29, 279—293. Compare *Abstr.*, 1908, ii, 915).—The author summarises the chemical changes already investigated when various substances are exposed to sunlight in the presence of uranium salts. He now shows that various other inorganic substances exert a similar action, and gives the qualitative results of the exposure of solutions of forty-five different substances in the presence of ferric sulphate. Most of these substances show changes of degradation. Certain reactions were also

quantitatively investigated. In the case of alcohols, the amount of aldehyde formed was estimated; in that of α -amino-acids and peptones, the amount of ammonia evolved in deamidisation; in that of β -amino-acids, the amount of amino-aldehyde formed. In the case of *l*-glucose, the diminution of fermentable sugar was estimated, and in those of the disaccharides, the amount of inversion. The amount of uric acid destroyed was also estimated, and also the amount of phosphoric acid set free from nucleic acids, and the amount of salicylic acid formed from benzoic acid.

Photo-electric Experiments with Anthracene. WALTER STEUBING (*Ber. Deut. physikal. Ges.*, 1910, 12, 867—868).—A reply to criticism on the part of Byk and Borck (this vol., ii, 814) of previous experiments by Stark and Steubing (*Abstr.*, 1908, ii, 746) on the photo-electric sensitiveness of anthracene. The experimental arrangement employed is described, and reasons are advanced in support of the validity of the conclusion that anthracene is photo-electrically active.

H. M. D.

Nature of the Ionisation Produced by α -Rays. FRANK E. WHEELLOCK (*Amer. J. Sci.*, 1910, [iv], 30, 233—255).—Experiments have been made to test whether columnar ionisation affords a complete explanation of the lack of saturation obtained in α -ray ionisation when moderate fields are employed, or whether "initial re-combination" also plays any part. With a perpendicular field, the lack of saturation is less than with a parallel field, as Moulin found (*Abstr.*, 1908, ii, 921). The ratio of two currents obtained with a constant field and two sources of α -rays differing in intensity does not depend on the field when it is parallel to the path of the rays, but does when it is perpendicular, as though with strong currents the ions in different columns interspersed with one another. A theoretical expression based on the hypothesis of columnar ionisation gave a saturation curve different from the experimental, saturation being approached, as the field increases, more slowly than the expression required. On this and other data, the conclusion is drawn that possibly both the hypotheses of columnar ionisation and of initial re-combination may be necessary to explain all the peculiarities of α -ray ionisation.

F. S.

Absorption and Reflexion of the β -Particles by Matter. ALOIS F. KOVARIK (*Phil. Mag.*, 1910, [vi], 20, 849—866).—The radioactive substances employed, radium-*D* and -*E*, actinium-*C'*, radium-*B*, thorium-*A*, -*B*, -*C*, and -*D*, were deposited on very thin aluminium leaf the absorption and scattering of which is negligible. Such preparations covered directly with thin aluminium foil and placed some distance below the electroscope, give an absorption curve showing an increase in the ionisation for the first 0.05 to 0.01 mm. of aluminium, or equivalent thickness of tin, which is ascribed to scattering. When the distance of the absorbing foils from the preparation was increased, the maximum decreased in magnitude, until finally the reverse effect, studied by Crowther, showed itself. In a hemispherical ionisation chamber, arranged so that the path of all rays was the same, it was shown that

the rays reflected from the support beneath the preparation were always less penetrating than the direct rays, the less so the greater the atomic weight of the reflector. Measurements of the absorption coefficients of the various rays were taken with as much aluminium below as above the preparation to compensate for reflexion. The curves obtained were very nearly exponential.

For different β -rays the percentage of the radiation reflected increases with increase in the velocity of the rays and with the atomic weight of the reflector. For very penetrating β -rays [$\lambda(\text{cm.})^{-1}$ above 20], however, the percentage reflected again decreases. By multiple reflection from the sides of the ionisation chamber, the ionisation may be increased three and a-half times.

F. S.

The Reflexion of Homogeneous β -Particles of Different Velocities. ALOIS F. KOVARIK and W. WILSON (*Phil. Mag.*, 1910, [vi], 20, 866—870).—The β -rays of radium C, from a sealed bulb of radium emanation, were sorted out into homogeneous rays by a magnetic field, and entered a flat ionisation chamber, made of thin aluminium leaves, which could be inclined at different angles to the rays, and could be covered with reflecting substances. It was found that the power of substances to reflect the rays increased with the velocity of the rays, from $H\rho=1000$ to $H\rho=\text{about } 3000$, and then slightly decreased again, but the ratio of the reflective powers of lead and copper was the same whatever the velocity of the rays.

F. S.

The Heterogeneity of β -Rays from a Thick Layer of Radium-E. J. A. GRAY and W. WILSON (*Phil. Mag.*, 1910, [vi], 20, 870—875).—Using a thick layer of radium-D and -E, it was found that, although the whole radiation was absorbed exponentially [$\lambda(\text{cm.})^{-1}=43$] by aluminium, different bundles of rays of widely different penetrating power [$\lambda(\text{cm.})^{-1}$ from 13 to 62.5] could be sorted out by a magnetic field. When the rays had first to pass through aluminium, it was proved by magnetic deflexion measurements that the average velocity of the rays surviving was increased.

F. S.

The Deflexion by an Electrostatic Field of Radium-B on Recoil from Radium-A. SIDNEY RUSS and WALTER MAKOWER (*Phil. Mag.*, 1910, [vi], 20, 875—882).—Some, at least, of the atoms of radium-B recoiling from radium-A are positively charged, although in the disintegration of radium-A positively charged α -rays are also expelled. The "recoil atoms" from a wire made active by a deposit of radium-A were passed between oppositely charged plates in a vacuum and fall upon a metal cross-piece. The distribution of the activity on the latter was determined by moving it under a narrow slit in the base of an α -ray electroscope. The point of maximum distribution was shifted by the application of a field to the plates, and from the magnitude of the shift the charge carried by the "recoil atoms" was deduced, on the assumption that the velocity of the atoms was 3.27×10^7 cm. per second, which is that calculated from the principle of equality of momentum of the two parts of a disintegrating atom.

The values obtained indicated that the recoil atom carries unit positive charge, and that its mass is 214, in agreement with what is to be anticipated from the disintegration theory.

F. S.

The Deflexion by a Magnetic Field of Radium-*B* on Recoil from Radium-*A*. WALTER MAKOWER and E. J. EVANS (*Phil. Mag.*, 1910, [vi], 20, 882—886).—Similar experiments to those described in the preceding abstract were carried out, the "recoil atoms" being deviated in a magnetic instead of an electrostatic field. The distribution of the activity on the cross-piece was determined by laying it on a photographic plate, and then measuring the photograph obtained by projecting it on to a screen by means of a lantern. The value for $H\rho$ of the deflected "recoil atoms" was 6.52×10^5 . This is twice that obtained by Rutherford for the α -particle of radium-*A*, and, since $H\rho = mv/e$, and the value of mv must be the same in both cases on the principle of equality of momentum, it follows that the charge carried is the unit charge instead of twice the unit charge, as in the case of the α -particle. By combining the results of the electrostatic and magnetic deflection measurements, it follows that the velocity of the "recoil atom" is 3.23×10^7 , and its mass is 194 ($H=1$), which is as close to the theoretical value 214 as can be expected.

F. S.

Measurements of the Rate at which Helium is Produced in Thorianite and Pitchblende, with a Minimum Estimate of their Antiquity. (Hon.) ROBERT J. STRUTT (*Proc. Roy. Soc.*, 1910, A, 84, 379—388).—A description is given of the methods employed to measure the rate of production of helium from solutions of thorianite (two varieties, one specially rich in uranium from the Galle district of Ceylon) in nitric acid, and of pitchblende. The latter was dissolved in nitric acid, and the insoluble sulphates converted into carbonates and dissolved to form a separate solution. The solutions were contained in large flasks closed by barometer tubes dipping beneath mercury, and the gaseous contents were removed periodically with steam by boiling the liquids. The volume of helium was estimated in the expelled gas after subjection to cooled charcoal in a narrow capillary tube. The rate of production of helium per gram of mineral per annum was found to be $3.7 (\times 10^{-8})$ c.c. for Galle thorianite, containing 24.5% of U_3O_8 and 65.44% of ThO_2 ; 2.79 for ordinary thorianite, containing 13.10% of U_3O_8 and 72.65% of ThO_2 ; and 3.16 for pitchblende, containing 37.6% of U_3O_8 . These results are in good agreement with those calculated earlier on certain assumptions. The minimum ages of the two thorianites are 2.50 and 2.80 ($\times 10^{-8}$ years) respectively, as calculated from the period required to produce the contained helium, no allowance being made for the helium that escapes. The minimum ages of 4 minerals previously worked with are, in millions of years, (1) sphærosiderite (Oligocene) 8.4, (2) hæmatite (Eocene) 31, (3) hæmatite (Carboniferous limestone) 150, (4) sphene (Archean) 710.

F. S.

Disengagement of Emanation from Radium Salts. III. LÉON KOLOWRAT (*Le Radium*, 1910, 7, 266—269. Compare this vol., ii, 31).—With barium chloride containing only minute proportions

of radium chloride, the disengagement of emanation from the salt at a temperature θ , after a period of accumulation t from the moment of complete removal of emanation by fusing the salt, is the same whether the temperature is maintained at θ throughout or for only a short time at the end of the period of accumulation, and is represented by $c(1 - e^{-\lambda t})/\lambda$, where λ is the constant of the emanation, and c a coefficient between 0 and 1, which is a function of θ , but independent of t ; c may be considered as the fraction of the emanation generated retained by the solid salt at θ , and may be determined with consistency in different experiments at the one temperature for different times for the same preparation, but varies greatly with different preparations otherwise apparently similar. Impure preparations seem to have lower values of c than those only containing barium and radium chloride. The idea that part of the radium chloride is in the form of a solid solution in the barium chloride and gives up its emanation more readily than the rest supposed to be present with the barium chloride in the form of mixed crystals (Kolowrat, this vol., ii, 767) does not account for the differences, as there is no regular relation between the value of c and the proportion of radium present. Using a few thousandths of a milligram of pure radium chloride, it was found that heating to the fusion temperature no longer effected complete release of the accumulated emanation, the material being changed by high temperature into an insoluble and probably infusible product. This agrees with Mme. Curie's observation that heating reduces the escape of emanation from radium chloride, and was confirmed by observations on the minimum β -radiation attained by the preparations after heating. The 1% barium-radium chlorides are less easily changed by heat, and give up the whole of their contained emanation by fusion.

F. S.

Action of Radium Emanation on Colloids. WILLEM P. JORISSEN and H. W. WOUDESTRA (*Chem. Weekblad*, 1910, 7, 941-948. Compare Henri and Mayer, Abstr., 1904, ii, 184).—The authors confirm the results obtained by Henri and Mayer in their work on the action of radium emanation on colloids. They find that the sensitivity of a colloid towards an electrolyte is increased by this emanation.

A. J. W.

The Diffusion of Gaseous Ions. ÉDOUARD SALLES (*Compt. rend.*, 1910, 151, 712-714).—The coefficients of diffusion of ions in carefully dried air, carbon dioxide, nitrogen, and oxygen, produced by the α -rays of polonium, have been measured by a method the principle of which is due to Townsend. The values are in accord with those given by Townsend for ions produced in other ways, the positive ion for oxygen ($k=0.030$) being the only one in disagreement. Experiments under pressure p (mm. of mercury) showed for $p \times k$ constant values of about 22 for the positive, and 32 for the negative, ions in air and nitrogen.

F. S.

Attempts to Prepare Metallic Radium. ERICH EHLER (*Ber.*, 1910, 43, 2613-2618).—From 0.02 gram of barium bromide con-

containing 2.5% of radium bromide, about 1 mg. containing 9% was prepared by crystallisation, converted into carbonate, and dissolved in aqueous hydrazoic acid. On evaporation, a white, crystalline mass of radium azoimide, $\text{Ra}(\text{N}_3)_2$, containing barium azoimide was left. Previous experiments with barium azoimide had shown that it is not decomposed by the action of radium rays. The preparation was brought into a narrow "melting-point tube," supported inside a perfectly exhausted glass tube, and heated in a special sand-bath very slowly to $180-250^\circ$. After some hours, a shining metallic mirror was formed, which was sealed off from the preparation, and found to contain 73% of the radium employed, by electroscopic measurements. The radium mirror was dissolved out of the tube and converted into chloride. In spite of the impurity of the preparation, the experiment proves that elementary radium is chemically and physically analogous to elementary barium. It appears to form nitride with moist air even more readily than barium.

F. S.

The Radium Content of Waters of the Cam, Cambridge Tap Water, and Some Varieties of Charcoal. JOHN SATTERLEY (*Proc. Camb. Phil. Soc.*, 1910, 15, 540-544).—The emanation generated per litre of Cambridge tap water and of Cam river water respectively is that in equilibrium with 130 and 5 ($\times 10^{-12}$ gram of radium), while the amount of radium is 1.6 and 3.2 ($\times 10^{-12}$ gram). The Cambridge waters are therefore richer in radium than those of Montreal, which accounts for the higher values found for the quantity of emanation in the air of Cambridge than in that of Montreal. In four varieties of charcoal, the radium contents per gram were: (1) cocoanut 0.4, (2) cocoanut 0.3, (3) Brazil-nut 1.3, (4) wood 0.3 ($\times 10^{-12}$ gram).

F. S.

Investigations on the Radium Content of Rocks. I. ERNST H. BÜCHNER (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 359-365).—The investigation includes ten rocks from the West Coast of Sumatra, comprising quartz porphyrite, granite, basalt, andesite, augite-andesite, granitite, diorite, and diabase. These rocks showed a content of radium of the order of 10^{-12} gram per gram, similar in magnitude to those which have been examined by other investigators. The highest was a basalt from the volcano of Asar (13.0), and the lowest were the diorite and diabase (0.3×10^{-12} gram of radium per gram).

F. S.

The Radium Content of Basalt. (Hon.) ROBERT J. STRUTT (*Proc. Roy. Soc.*, 1910, A, 84, 377-379).—The discrepancy between the author's results and those of Joly on the radium content of igneous rocks is greatest in the case of basalts, the value found by the latter being about eight times that found by the former. New measurements with special precautions have therefore been made on a new set of three basalts, which give results even lower than the previous set (from 0.16 to 0.35×10^{-12} gram radium per gram), whilst in one sample previously employed a new determination gives the same result as before (0.57). It is possible that Joly has met with exceptional specimens.

F. S.

The Presence of Radioactive Elements in Some Incrustations from the Fumaroles of Vesuvius. GIUSEPPE KERNOT (*Rend. Accad. Sci. Fis. Mat. Napoli*, 1910, [iia], 16, 48—50. Compare Abstr., 1907, ii, 365).—Incrustations from recent fumaroles, dissolved in hydrochloric acid and precipitated with hydrogen sulphide, yield a mixture of sulphides, from which, after removing arsenic by ammonium sulphide, boiling with dilute hydrochloric acid, and dissolving in nitric acid, lead is removed as sulphate, and a greyish-white precipitate is then obtained by the addition of ammonia. This precipitate is markedly radioactive. C. H. D.

The Radioactivity of the Products of the Recent Eruption of Etna. ARNALDO PIUTTI and GENNARO MAGLI (*Rend. Accad. Sci. Fis. Mat. Napoli*, 1910, [iia], 16, 159—163).—The products of the recent volcanic eruption of Etna have been studied in the same manner as those of Vesuvius (this vol., ii, 290). The smallest radioactivity is possessed by the volcanic sands, followed in ascending order by the lava, the scorie, and the sublimed products and incrustations. The maximum activity agrees with that of the materials obtained from the preceding eruption, and is greater than that of corresponding materials from the last eruption of Vesuvius, in which, however, the same relative order is observed. C. H. D.

Radioactivity of Italian Minerals. RAFFAELLO NASINI and MARIO G. LEVI (*Gazzetta*, 1910, 40, ii, 101—122. Compare Abstr., 1909, ii, 7, 110).—A complete account of the work on this subject carried out by the authors and others. R. V. S.

A Determination of the Ratio of Mass to Weight for a Radioactive Substance. L. SOUTHERNS (*Proc. Roy. Soc.*, 1910, A, 84, 325—344).—The ratio of mass to weight of the oxides of lead and of uranium have been compared by filling the hollow bob of a specially constructed rigid pendulum with these two substances, and no difference between them has been indicated. The ratio is the same for the two substances within one part in 200,000. F. S.

Electrical Purification and Conductivity of Liquid Sulphur Dioxide. J. CARVALLO (*Compt. rend.*, 1910, 151, 717—719).—When a current is passed through liquid sulphur dioxide free from air between platinum electrodes, the difference of potential being V , it is found that the current I diminishes with time until a limit is attained. The negative electrode becomes slightly brown, and the liquid undergoes purification by prolonged passage of the current.

When V is 200—500 volts, the limiting current does not vary as a simple function of V . With a difference in potential of 1000 or 2000 volts, the current is much smaller than that passing with lower tensions. Curves plotted for $I=f(V)$ are in accordance with Ohm's law, when V does not exceed 100 volts. The limiting conductivity for higher voltages is not in agreement with this; the law governing it under these conditions appears to resemble the laws for the conductivity of gases, and will be further studied. The limiting specific

resistance under 100 volts was 7.6×10^9 ohms; under 2350 volts, 4.9×10^{10} ohms, and under 4000 volts, 4.9×10^{10} ohms per cm.

W. O. W.

Electrical Conductivity of Solutions in Aniline, Methyl-aniline, and Dimethylaniline. AL. SACHANOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 683—690).—The object of the research was to determine the connexion between the chemical nature of an amine and its dissociating power and its power of giving conducting solutions. Since the dielectric constants of the three amines are very close to one another, any difference that may exist in their dissociating powers would be due to the difference in their chemical constitutions. The following salts were employed: ammonium iodide, pyridine hydrobromide, aniline hydrobromide, silver nitrate, and lithium iodide, and tables and a curve for aniline solutions are given, showing the relation of concentration to electrical conductivity. All the solutions show a rapid diminution of their molecular electrical conductivity with increasing dilution, this probably being due to the formation and dissociation of complex salts, such as $\text{NH}_4\text{I}, 2\text{PhNH}_2$, $\text{AgNO}_3, 2\text{PhNH}_2$. Aniline gives the best conducting solutions, methylaniline comes next, whilst the solution in dimethylaniline seems to be on the border between conducting and non-conducting solutions. The conclusion is drawn that the chief factor determining the ability to give conducting solutions is the chemical constitution of the amine.

Z. K.

The Potential of the Sodium Electrode. GILBERT N. LEWIS and CHARLES A. KRAUS (*J. Amer. Chem. Soc.*, 1910, 32, 1459—1468).—A method of obtaining the difference of potential between metallic sodium and a solution of sodium ions of normal concentration is described. This consists in determining the potential difference between a dilute sodium amalgam and an aqueous solution of sodium hydroxide, and also the *E.M.F.* of the cell metallic sodium | sodium iodide dissolved in ethylamine | sodium amalgam. The *E.M.F.* of this galvanic combination is independent of the medium in which the sodium salt is dissolved, and ethylamine was chosen because it is not acted on by the alkali metal.

The *E.M.F.* of the combination sodium amalgam (0.206% sodium) | 0.2*N*-sodium hydroxide | normal calomel electrode was found to be 2.1986 volts. Assuming that the sodium hydroxide is ionised to the extent of 82.8%, this gives for the *E.M.F.* of the cell sodium amalgam | aqueous solution containing Na ions in normal concentration | normal calomel electrode, 2.1525 volts. The potential difference between sodium and 0.206% sodium amalgam is 0.8456 volt, and these data when combined give for the *E.M.F.* of the combination sodium | aqueous solution containing 1*N*-sodium ion | normal calomel electrode, 2.9981 volts at 25°.

The temperature-coefficient of the sodium-sodium amalgam cell is -0.0000408 volt per degree, and from this it is calculated that the heat of solution of 1 gram-atom of sodium in 0.206% sodium amalgam is 19,790 cal.

The precautions to be observed in the preparation of pure sodium

amalgam and of anhydrous ethylamine are described in detail. If these are followed, the observed potential differences can be reproduced with great accuracy.

H. M. D.

Oscillographic Investigation of Some Electrolytic Processes.

III. D. REICHSTEIN (*Zeitsch. Elektrochem.*, 1910, 16, 916—944. Compare Abstr., 1909, ii, 960).—Using a more sensitive oscillograph (on the photographic record a deflexion of 1 mm. on the ordinate axis is given by a current of 0.0004 ampere, whilst 1 mm. on the axis of abscissae corresponds with 0.0006 second), the author has studied the polarisation of an electrode produced by a fairly strong current lasting a few hundredths of a second and its subsequent decay. The cases examined are the anodic and cathodic polarisation of platinum (also mercury and silver) in 28% sulphuric acid; the anodic polarisation of copper, silver, lead, and nickel in solutions of their salts, and the cathodic polarisation of palladium in sulphuric acid and in acid zinc sulphate. In all the experiments the experimental electrode is combined with a large, unpolarisable electrode. The results are, as a rule, given in the form of reproductions of the oscillograph curves. The main result, however, is that during the passage of the polarising current, the difference of potential between the electrode and the solution is always much larger than the equilibrium *P.D.* when no current is flowing, and the difference increases with the current. The rate of disappearance of this excess depends on the nature of the product of electrolysis and of the electrode. The phenomenon is met with in every case examined; it is hardly possible to give the details, and also the possible mechanisms which the author suggests in explanation of them in a brief abstract. It may be said, however, that the view is taken that the primary products of the electrolysis are not identical with the stable substances finally formed, the decay of the excess polarisation being due to the transformation of one into the other. T. E.

The Potentials of Chlorine, Bromine, and Iodine in Methyl and Ethyl Alcohol. J. NEUSTADT (*Zeitsch. Elektrochem.*, 1910, 16, 866—869).—The *E.M.F.* of a cell $\text{Ag} | \text{saturated solution of AgCl} | \text{Cl}$ is independent of the solvent used. It is given by $E = \epsilon_{\text{Ag}} - \epsilon_{\text{Cl}} + RT/nF(\log[\text{Ag}'] + \log[\text{Cl}'])$. The quantity in the brackets is the logarithm of the solubility product of silver chloride, and ϵ_{Ag} and ϵ_{Cl} are the normal potentials of silver and chloride in the solvent used. From the value of *E* for aqueous solutions and determinations of the solubility products of the silver haloids in the alcohols, the differences of the normal potentials of the haloids in alcoholic solutions are therefore easily calculated. The solubility products in alcoholic solutions are obtained by measurements on concentration cells of the type $\text{Ag} | 0.1N\text{-AgNO}_3 | 0.1N\text{-KCl saturated with AgCl} | \text{Ag}$. The concentrations of the silver and chlorine ions in the alcoholic solutions are calculated from the conductivity measurements of Deimpf (Abstr., 1905, ii, 9). The mean values of the solubility products at 25° are:

| | Methyl alcohol. | Ethyl alcohol. |
|------------|------------------------|------------------------|
| AgCl | 1.95×10^{-13} | 1.85×10^{-14} |
| AgBr | 1.1×10^{-16} | 6.4×10^{-16} |
| AgI | 1.5×10^{-18} | 1.1×10^{-17} |

The differences of the normal potentials, calculated in the way indicated above, are :

| | Water. | Methyl alcohol. | Ethyl alcohol. |
|--|--------|-----------------|----------------|
| $\epsilon_1 - \epsilon_{\text{H}_2\text{O}}$ | 0.467 | 0.418 | 0.471 |
| $\epsilon_1 - \epsilon_{\text{Et}}$ | 0.772 | 0.707 | 0.712 |

Determinations in acetone were impossible, owing to formation of complex salts. T. E.

Heat Development of the Clark Cell. F. POLLITZER (*Zeitsch. physikal. Chem.*, 1910, 74, 748).—Cohen (Abstr., 1900, ii, 520, 703) has calculated from the heats of solution, etc., that the heat development of the Clark cell is 81,127 cal. in fair agreement with the value calculated from the variation of the *E.M.F.* with temperature, 81,490 cal. In calculating the latter value, however, an incorrect value of the electrical equivalent of heat has been used. The accurate value of the latter (1 watt-second = 0.2387 cal.) gives 82,402 cal. at 18°, which does not agree with the value calculated from the heats of solution, etc. G. S.

Piezoechemical Studies V. The Transition Element and its Applications. ERNST COHEN, KATSUJI ISOUYE, and C. ECKEN (*Zeitsch. physikal. Chem.*, 1910, 75, 1—29. Compare Abstr., 1909, ii, 981).—The transition temperature $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O} \rightleftharpoons \text{ZnSO}_4 \cdot 6\text{H}_2\text{O} + \text{H}_2\text{O}$ has been determined at intervals of pressure between 1 and 1500 atmospheres by means of so-called transition elements of two types. The first type, a modified Clark cell, was constituted as follows:

| | | |
|---|---|--|
| Electrode reversible with reference to anion. | Saturated solution of zinc sulphate in contact with the stable solid phase of the salt. | Electrode reversible with reference to cation. |
|---|---|--|

The *E.M.F.* of this element under different pressures was measured at temperatures above and below the transition point, and the latter, at a definite pressure, taken as the point at which the curves representing the influence of temperature on the *E.M.F.* above and below the transition temperature intersected. The other arrangement consisted of two cells, one of which contained a saturated solution of zinc sulphate in contact with the stable form of the salt, whilst the solution in the other was in contact with the metastable form of the salt (the hexahydrate). The temperature at which the *E.M.F.* becomes zero when these cells are set in opposition is the transition temperature.

The transition temperatures with the first type of cell are 38.12°, 38.96°, 41.19°, and 42.63°, and with the second type 38.10°, 39.90°, 41.35°, and 42.80° at 1, 500, 1000, and 1500 atmospheres respectively. The result at one atmosphere pressure is only in moderate agreement with those of previous observers, but is fully confirmed by a dilatometer experiment (38.10—38.20°). G. S.

Piezoechemical Studies. VI. ERNST COHEN and KATSUJI ISOUYE (*Zeitsch. physikal. Chem.*, 1910, 75, 219—231. Compare preceding abstract).—The effect of pressure on the *E.M.F.* of the cell of the second type already described (*loc. cit.*) has been determined indirectly by application of the equation: $E_\pi - E_0 = \pi(v_2 - v_1)$, where v_1 and v_2 represent the volumes of the system before and after

the passage of 96,540 coulombs, and π is the pressure. The factor $v_2 - v_1$ has been determined directly by putting pure zinc sulphate heptahydrate in a pycnometer, filling up with toluene as indifferent liquid, and finding the change of volume after transformation to the hexahydrate. Substituting in the above equation, the value $E_{500} - E_0 = 0.00088$ volt is obtained, as compared with the experimental value 0.00108 volt.

Further, the Clausius-Clapeyron equation:

$$dT/dp = 10,333T(\sigma - T)/427.2v,$$

where $(\sigma - T)$ is the change of volume in the transition of zinc sulphate heptahydrate, and v is the accompanying thermal effect, can be employed to find the effect of change of pressure on the transition temperature. Inserting the appropriate values of $(\sigma - T)$ and v , it is found that $dp/dT = 0.0032^\circ$, whereas the experimental value is 0.0036° .

Finally, another equation is derived thermodynamically, by means of which dp/dT can be calculated by means of electrical measurements. It leads to the value of $dp/dT = 0.0027^\circ$, instead of the experimental value given above.

G. S.

Thermo-[electric] Forces of Solid Solutions of Metals and Schenck's Law. AUGUST L. BERNOULLI (*Ann. Physik*, 1910, [iv], 33, 690—706).—Thermo-electric measurements have been made for various solid solutions of metals in order to test Schenck's formula $\pi = R/2e \cdot \log(k' \sigma' : k \sigma)$, in which π is the thermo-electric difference of potential between the pure metal and a solid solution containing a second metal, k and σ are the thermal and electric conductivities of the solvent metal, and k' and σ' the corresponding quantities for the solution.

Solutions of thallium and tin in silver, of mercury in cadmium, and of tin, zinc and nickel in copper, were investigated. For sufficiently dilute solutions the observed thermo-electric potential difference agrees with that calculated from Schenck's formula, and this agreement is particularly good when the atomic weight of the solute metal is considerably greater than that of the solvent metal. As the concentration of the solutions increases, the agreement becomes less satisfactory. In the case of the copper zinc alloys, the observed potential differences are much larger than those obtained by calculation, and this is attributed to the formation of the compound Cu_2Zn_3 .

H. M. D.

Electrophoresis of Lamp Black. ALBERT REYCHLER (*Bull. Soc. chim. Belg.*, 1910, 24, 345—354).—Using an apparatus similar to that described by Coehn (*Abstr.*, 1909, ii, 841), the author has investigated the electrophoresis of lamp black (Kahlbaum's) which had been subjected to different methods of purification in order to obtain a suspension in water. These methods were: (a) treatment with a mixture of potassium dichromate and concentrated sulphuric acid for eighteen hours, and subsequent washing with dilute hydrochloric acid and finally with water; (b) trituration with concentrated sulphuric acid and then washing as in (a); (c) warming with a dilute

solution of sodium in ordinary alcohol, and subsequent washing with alcohol and water; (d) no purification was attempted, but a suspension was obtained directly by introducing the lamp black into dilute alcohol, which was slightly alkaline. Suspensions could not be obtained when it was put directly into water.

The suspensions obtained were investigated as such, and after the addition of enough potassium hydroxide or hydrochloric acid to make them from $N/110$ to $N/11,000$. All alkaline suspensions showed the phenomenon of anaphoresis, and were fairly stable. Suspensions which were very feebly acid still showed anaphoresis, but when the acidity was increased ($N/110$) they were flocculated so rapidly that it was impossible to observe whether they showed cataphoresis (compare Perrin, Abstr., 1905, ii, 138). Details are also given of actual stability of the different suspensions and of the effect of filtration.

The remainder of the paper is occupied with a discussion of the detergent action of soap, special reference being made to the theories of Spring (this vol., i, 6) and of Chevreul. T. S. P.

The Nature of the Coloured Films Formed on the Alkali Metals by Electric Discharges. JULIUS ELSTER and HANS GEITEL (*Physikal. Zeitsch.*, 1910, 11, 1082—1083. Compare this vol., ii, 379).

—The coloured substances which are formed on the surface of the alkali metals when subjected to the influence of the glow discharge in hydrogen at low pressure have been described as colloidal solutions of the metals in the corresponding hydrides. It is pointed out that the colours of the different substances are identical with those of the corresponding modifications of the alkali metals obtained by Fischer and Schröter (this vol., ii, 609) by the disintegrating action of the arc discharge on alkali metal electrodes immersed in liquid argon. The two series of coloured substances obtained by the two methods are considered to be identical.

The presence of hydrogen is supposed to facilitate the formation of the colloidal metals under the influence of the glow discharge by forming hydrides which act as solvents for the metals. Since hydrogen was in all probability present in the arc discharge experiments of Fischer and Schröter, the formation of the colloidal metals in these circumstances may be in some measure due to the preliminary formation of hydrides.

When potassium is subjected to the glow discharge at the temperature of liquid air, the coloured film is not formed to any appreciable extent, and this is attributed to the absence of the hydride, which is not formed in consequence of the low vapour pressure of the alkali metal at this temperature. H. M. D.

Specific Heats and Gas Equilibria from Explosion Experiments. II. MATHIAS PIER (*Zeitsch. Elektrochem.*, 1910, 16, 897—903). —The manometer previously used (Abstr., 1909, ii, 789) is improved by fixing the mirror directly to the corrugated diaphragm about midway between its centre and its periphery.

By exploding acetylene (a) with excess of air, (b) with excess of

oxygen, and (c) with excess of carbon dioxide, data are obtained from which the ratios of the specific heats of carbon dioxide or of oxygen to that of nitrogen are calculated. The molecular heat of oxygen, up to 2200° , is the same as that of nitrogen ($4.900 + 0.00045t$). The formulæ of Holborn and of Langen do not represent the results obtained for carbon dioxide; a new equation is therefore proposed for the mean molecular heat of carbon dioxide between 0° and t° at constant volume: $c = 6.800 + 3.3 \times 10^{-3}t - 0.95 \times 10^{-6}t^2 + 0.1 \times 10^{-9}t^3$. This represents both the author's results between 1600° and 2100° and those of Holborn and Henning ($200-1364^{\circ}$), with sufficient accuracy.

The molecular heat of sulphur dioxide is obtained from explosions of carbon disulphide with oxygen. It is the same as that of carbon dioxide up to 2000° .

The dissociation of carbon dioxide is calculated from the results of explosions of mixtures of carbon monoxide and oxygen on the assumptions that carbon monoxide has the same molecular heat as nitrogen, and that the above expression for carbon dioxide holds up to 3000° . The results are too high, which is taken to indicate that the specific heat of carbon dioxide increases more rapidly above 2000° . An attempt to measure the equilibrium $\text{CO}_2 + \text{H}_2 = \text{H}_2\text{O} + \text{CO}$ also failed for reasons which are not clearly understood.

T. E.

Critical Phenomena of Ethyl Ether. F. B. YOUNG (*Phil. Mag.*, 1910, 20, 793-828).—Observations relating to the nature of the critical phenomena in ethyl ether are described and discussed in reference to Andrews's theory.

It has been frequently observed that when a liquid in contact with its vapour is heated to the critical temperature, the meniscus disappears, whilst the density of the liquid is still distinctly greater than that of the vapour, and that this difference of density may persist for a considerable time, even when the temperature is raised above the critical temperature. Various explanations of this have been offered, some of which attempt to reconcile it with Andrews's theory, whilst others regard it as evidence of the incompleteness of this theory.

The ethyl ether used in the experiments was purified as completely as possible, and elaborate precautions were taken to free it from traces of air, for observations made with different tubes containing extremely small quantities of gaseous impurities indicate that these may visibly modify the critical phenomena. The Jena glass tubes containing the ether were heated in an aniline vapour-bath, the temperature of which could be adjusted very exactly by regulation of the pressure. Sliding freely inside each tube was a bell-shaped piece of tubing sealed on to a closed tube containing iron filings, which enabled the bell to be raised or lowered by means of an electro-magnet. This arrangement was found to give a very delicate means of testing the contents of the tubes for traces of gaseous impurities.

The conclusion drawn from the observations is that the critical phenomena observed with the pure substance can be explained in accordance with Andrews's theory, and that the phenomena advanced in support of the insufficiency of this theory are to be observed only

in tubes which contain traces of impurities. The part played by hydrostatic pressure is, in all probability, negligibly small, and the differences in density which are observed on the disappearance of the meniscus are apparently due to slight differences in temperature.

From a study of the phenomena of opalescence, the author considers that the opalescence is not due to the formation of an emulsion, but to variations in the temperatures of the individual molecules, as has been supposed by Küster.

In an appendix, a vapour thermostat for experiments on critical phenomena is described. The vapour-jacket is connected with a large flask, which communicates with a closed mercury manometer. This is provided with a short arm, in which is a float which makes electrical contact with a platinum-tipped needle. When contact is made, a relay is actuated, and a current is sent through a coil of fine wire contained in the large flask. The heat developed causes the air to expand until the consequent rise of pressure breaks the contact. By wrapping the coil of wire in cotton wool, the change of pressure is made to take place less suddenly, and the mercury in the gauge is thus enabled to follow the change of pressure more closely.

H. M. D.

Influence of the Surface of a Solid Phase on the Latent Heat and on the Melting Point. P. N. PAWLOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 677—680. Compare *Abstr.*, 1909, ii, 13, 295).

—The formula obtained by the author connecting the melting point with the surface energy of a phase is now deduced by another method, and a further formula is given showing in what direction the melting point of small particles varies as compared with that of large ones. If small particles have a smaller heat of fusion, then the temperature at which they melt is lower than that of the large particles; if their heat of fusion is greater, then the melting point is higher than that of the large ones.

If the free surface energy of a solid phase is less than the free surface energy of the liquid phase, then the increase of surface of the solid phase is accompanied by a rise in its heat of fusion, and vice versa. If the free surface energy of the solid and liquid phases are equal, then the change in the size of the surface exerts no influence on the latent heat of fusion (see further, this vol., ii, 1043).

Z. K.

Influence of Degree of Dispersion of Solid Crystalline Substances on their Melting Points. P. P. VON WEIMARN

(*J. Russ. Phys. Chem. Soc.*, 1910, 42, 647—653).—A short discussion of the author's previous work on this subject. The properties of the surface layer of a crystal resemble, although they are not identical with, those of the interior of a strongly compressed liquid, whilst the superficial layer of a liquid resembles the interior of a strongly compressed gas; therefore, with an increase in the degree of dispersion, a solid, crystalline substance becomes more active chemically, more volatile, more soluble, and more readily fusible. The two most important factors in determining the structure and properties of the surface layer of a crystal are: (1) the unilateral action of the vectorial molecular forces

on the molecules, forming the free surface of the crystal. (*B*) The dynamic (kinetic molecular) processes occurring on the free surface of the crystal. *A* gives rise to the capillary pressure, which is superadded to the external pressure on the surface, and increases with the degree of dispersion; consequently, as the degree of dispersion increases, so *A* tends to diminish the similarity between the surface of the crystal and a liquid, the melting point, in general (except in cases such as ice), rising with an increase in pressure. *B*, on the other hand, tends to increase the similarity between the surface of a crystal and a liquid, and since a fine disperse system is almost always more active than a coarse one, *B* acts as a more energetic factor than *A*. In addition, the melting point is lowered in a system of great dispersion by the fact that the surface of the crystals dissolves the surrounding medium until saturated; consequently, the melting point and other physical properties of a disperse system varies with the nature of the medium by which it is surrounded, or from which the crystals have been separated, and the greater the degree of dispersion the more marked is this variation.

Z. K.

The Spontaneous Crystallisation and the Melting- and Freezing-Point Curves of Mixtures of Two Substances which form Mixed Crystals and Possess a Minimum or Eutectic Freezing Point. Mixtures of Azobenzene and Benzyllaniline. FLORENCE ISAAC (*Proc. Roy. Soc.*, 1910, *A*, 84, 344-369).—From freezing- and melting-point observations with mixtures of azobenzene and benzyllaniline, it has been found that these substances form a eutectic mixture which solidifies at 26° and contains 19% of azobenzene. Mixed crystals are formed by mixtures containing more azobenzene than the eutectic, but not by mixtures which contain less. The form of the melting-point curve was confirmed by analysis of the mixed crystals.

The temperatures at which different mixtures undergo spontaneous crystallisation were also determined by two different methods, and in this way the supersolubility curve was obtained. This curve exhibits a minimum for liquids which have approximately the composition of the eutectic mixture, and, for the most part, it runs nearly parallel to the freezing-point curve. The supersolubility curve, on the other hand, cuts the melting-point curve at three different points. The mixed crystals which separate out on spontaneous crystallisation along the supersolubility curve have been determined for various liquid mixtures of the two substances. Microscopic examination of sections cut from the solid solutions indicates that gradual changes take place in these mixed crystals at the ordinary temperature.

H. M. D.

Freezing Mixtures. JACQUES DECLAUX (*Compt. rend.*, 1910, 151, 715-716).—A description of a simple method for attaining low temperatures. Two liquids, which produce a fall in temperature on mixing, are allowed to flow through two long glass tubes (diameter, 1 mm.). The liquids leave the tubes at the rate of 1 to 2 drops per second, and then mix. The mixture is caused to flow over the tubes before leaving the apparatus, thus lowering the temperature of the incoming liquids. By this method a temperature of -45° can

be maintained for long periods, employing 100 c.c. of carbon disulphide and 70 c.c. of acetone per hour. In one experiment, a volume of 20 c.c. was kept at -43.5° with this mixture in a double-walled, silvered glass tube, the external temperature being 22° . W. O. W.

Condition of Substances in Solution in Absolute Sulphuric Acid. V. GIUSEPPE ODDO and E. SCANDOLA (*Gazzetta*, 1910, 40, ii, 163—209. Compare Abstr., 1909, ii, 377, 792, and Hantzsch, *ibid.*, ii, 973).—Since in the opinion of the authors the condition of alcohols in solution in absolute sulphuric acid has now been settled, they have proceeded to the study of the ethers and esters. In a polemical appendix, the objections raised by Hantzsch are discussed, further inaccuracies in his results are suggested, and finally the authors' views on the whole question under examination are set forth.

In calculating from the cryoscopic measurements the molecular weights of the substances in solution, a correction is introduced for the proportion of the dissolved substance which has been acted on by the sulphuric acid, the correction being obtained by neutralising the remaining sulphuric acid with barium hydroxide and weighing the barium sulphate obtained. When this is done, it is found that the molecular weights amount to very nearly 50% of the theoretical in the case of all the following ethers: ethyl ether, propyl ether, *n*-butyl ether, *iso*amyl ether, *n*-heptyl ether, dimethylpyrone. Hence all these ethers yield an acid oxonium sulphate which dissociates.

In the case of the esters ethyl acetate and ethyl monochloroacetate, it is found that decomposition (to the extent of 15.35% and 32.9%, respectively) occurs, although Hantzsch has stated otherwise in regard to the former substance. Taking this decomposition into account, the molecular weights are 55% and 62% respectively of the theoretical values, showing that the esters are weaker oxonium bases than the ethers, the weakness being greater the more negative the radicle which they contain. The authors consider that when an ester is dissolved in absolute sulphuric acid, three changes occur: (1) formation of the acid oxonium sulphate, which dissociates into two ions; (2) molecular dissociation of part of this salt; (3) partial decomposition of the ester into two acids, namely, the alkyl hydrogen sulphate, and the acid corresponding with the contained radicle. Of these, the second tends to give values above 50%, the third values below that. Hence the mere cryoscopic measurement may indicate 50%. Results according with this view were obtained also with *iso*amyl formate, *iso*amyl acetate, and *iso*amyl butyrate.

Experiments with ethyl nitrate, *iso*amyl nitrate, and *iso*amyl nitrite show that with increase in the negative character of the acid radicle (as compared with those of the ethers and esters already mentioned), the acid decomposition of the molecules reaches a maximum, and no indication of an oxonium salt can be found. *sec*-Butyl nitrate gives results indicating that the difference between primary and secondary alcohols already noticed (*loc. cit.*) exists also in the case of the esters. Methyl sulphate has not the normal molecular weight, as stated by Hantzsch. On the contrary, the authors advance reasons for supposing that a large part of it is decomposed to form the

acid ester, and that in addition complex molecules, such as $\text{Me}_2(\text{HSO}_4)_2$, also exist in the solution.

R. V. S.

Some Molecular Weights in Phosphoryl Chloride as a Cryoscopic Solvent. PAUL WALDEN (*Zeitsch. anorg. Chem.*, 1910, 68, 307—316).—Phosphoryl chloride has been used as a cryoscopic solvent by Oddo (Abstr., 1901, ii, 492,; 1904, ii, 236), who found the melting point to be -1.782° , and the cryoscopic constant 70.16 . The author finds the melting point to be $+1.25^\circ$, and the cryoscopic constant, determined as the mean of experiments with several compounds, 76.8 , corresponding with a latent heat of fusion of 19.8 Cal.

Simple molecular weights are given by the compounds ICl , IOX , N_2O_3 , Cl_2O_7 , and OsO_4 . Phosphoric oxide, chromic acid, and iodine pentoxide are practically insoluble in phosphoryl chloride.

The cryoscopic constant of bromoform is 144 . Both solid α - and liquid β -iodine chloride are unimolecular in bromoform.

C. H. D.

Dicyclohexyl as a Cryoscopic Solvent. LUIGI MASCARELLI and L. VECCHIOTTI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 410—414).—For the purpose of comparison with cyclohexane (Abstr., 1909, ii, 19, 972) the behaviour of dicyclohexyl, $\text{C}_6\text{H}_{11}\cdot\text{C}_6\text{H}_{11}$, prepared by the reduction of diphenyl by hydrogen in the presence of nickel, has been examined. The cryoscopic constant has a mean value of 145.2 . The solubility of most substances in this solvent in the cold is small. Phenol, propyl alcohol, and acetic acid are associated, even in dilute solution. The general behaviour of ketones and nitro-compounds in dicyclohexyl closely resembles that of the same substances in cyclohexane. Tetranitromethane, however, is normal.

C. H. D.

Vapour Pressure Curves. DEMETRIUS E. TSAKALOTOS (*Zeitsch. physikal. Chem.*, 1910, 75, 743—746. Compare this vol., ii, 266).—The minimum of vapour pressure in the binary mixture chloroform-ethyl ether is probably connected with the formation of a compound $\text{Et}_2\text{O}\cdot\text{CHCl}_3$. From the results of surface-tension and vapour pressure measurements, it appears that liquid oxygen is polymerised, whereas according to Walden's boiling-point formula (Abstr., 1909, ii, 122) it is unimolecular.

G. S.

Studies in Vapour Pressure. III. A Static Method for Determining the Vapour Pressures of Solids and Liquids. ALEXANDER SMITH and ALAN W. C. MENZIES (*J. Amer. Chem. Soc.*, 1910, 32, 1412—1434; *Ann. Physik*, 1910, [iv], 33, 971—978. Compare this vol., ii, 687, 688).—The sources of error involved in vapour pressure measurements are discussed, and a critical résumé is given of the various methods which have been employed in such determinations. A new form of apparatus, called the *static isothermoscope*, is described, and it is claimed that by means of this apparatus more trustworthy measurements of vapour pressures can be made than by the older methods. It consists of a small U-tube, one limb of which is connected with a small spherical bulb, and the other with a long vertical tube, which communicates with a mercury

gauge and with a large iron bottle, which in turn can be put into communication with (1) the atmosphere, (2) a vacuum reservoir and water pump, or (3) a pressure reservoir and compression pump. The lower half of the U-tube is occupied by a confining liquid, and to prevent the ascent of this into the spherical bulb containing the vaporising liquid or into the long vertical tube, small bulbs are blown on the upper end of each limb of the U-tube. The liquid under investigation may be conveniently employed as confining liquid.

In the manipulation of the apparatus, the temperature of the liquid bath, in which the isoteniscope is immersed, is fixed, and the pressure in the iron bottle is then adjusted until the liquid in the bulb boils freely. After the removal of all air and dissolved gases, the pressure is cautiously increased until the levels of the confining liquid are the same in both limbs of the U-tube. To ensure that all foreign gases have been expelled, the process of boiling and adjusting of the pressure is repeated until constant pressure values are recorded on the gauge.

To test the results obtainable with this apparatus, the authors have measured the vapour pressure of water between 50° and 90°, the isoteniscope being immersed in a thermostat, the temperature of which was determined by means of a resistance thermometer. The data obtained are in close agreement with the measurements of Holborn and Henning.

H. M. D.

Studies in Vapour Pressure. IV. A Redetermination of the Vapour Pressures of Mercury from 250° to 435°. ALEXANDER SMITH and ALAN W. C. MENZIES (*J. Amer. Chem. Soc.*, 1910, 32, 1434—1447; *Ann. Physik*, 1910, [iv], 33, 979—988).—The measurements were made by means of the static isoteniscope (compare preceding abstract). From the vapour pressures, 106.52 mm. at 264.16°, 760 mm. at 356.95°, and 2598.67 mm. at 433.96°, a Kirchhoff-Rankine-Dupré formula has been obtained, which may be written: $\log p = 9.9073436 - 3276.628/\theta - 0.6519904 \log \theta$. The experimental data, which agree well with the pressures calculated from this equation, are compared with the older measurements of Gebhardt, Regnault, Ramsay and Young, and with the probable values calculated by Laby (*Abstr.*, 1908, ii, 1039) from the several known series. The divergences between the authors' measurements and the values adopted by Laby are not inconsiderable, the difference amounting to 15 mm. at 450°.

A table is given showing the vapour pressures of mercury for every 2° between 0° and 450°; these pressures are the values obtained from the formula given above. The temperatures refer to the thermodynamic scale, and the pressures to the normal value of gravity.

H. M. D.

Studies in Vapour Pressure. V. A Dynamic Method for Measuring Vapour Pressures, with its Application to Benzene and Ammonium Chloride. ALEXANDER SMITH and ALAN W. C. MENZIES (*J. Amer. Chem. Soc.*, 1910, 32, 1448—1459; *Ann. Physik*, 1910, [iv], 33, 989—994).—The authors describe a modified form of

apparatus for the dynamic measurement of vapour pressures (compare this vol., ii, 687, 688). The apparatus, which is immersed in a well-stirred liquid bath, consists of a small bulb, which communicates through a narrow tube with a small reservoir containing a suitable confining liquid. The tube is sealed through the upper wall of the reservoir, and terminates beneath the surface of the confining liquid. By means of a long vertical tube, the reservoir can be put into communication with a pump or compression apparatus.

This so-called *dynamic isotenoscope* has been employed for the measurement of the vapour pressure of benzene between 65° and 120°, and that of ammonium chloride between 280° and 333.5°. The results are compared with those of previous observers, who have used both static and dynamic methods of measurement. In the case of ammonium chloride, the authors' vapour pressure curve lies between the curves representing the data of Ramsay and Young and those of Johnson (Abstr., 1908, ii, 157).
H. M. D.

The Composition and Vapour Tension of Solutions. III. The Influence of Temperature on the Composition of Solutions. M. S. VREYSKY (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 702—714).—The solutions of ethyl, methyl, and propyl alcohol in water have been investigated. Curves are given showing the relation between the %molecular composition of the solutions and the %molecular composition of the vapour at various temperatures for each pair of liquids, and the composition of the constant boiling point solution of propyl alcohol and water is deduced graphically. As the temperature of the solution of methyl and ethyl alcohol in water rises, the relative proportion of water in the vapour increases, whilst in the case of propyl alcohol, the proportion of alcohol in the vapour increases under similar conditions. These facts are deduced theoretically and shown to agree with experiment.
Z. K.

Micro-distilling Apparatus. A. GAWALOWSKI (*Zeitsch. anal. Chem.*, 1910, 49, 744—745).—The apparatus consists of a very small flask (or test-tube), the neck of which is shaped like the head of an alembic. For very volatile liquids, by means of a cork, a small, inverted condenser is attached, the tube from which is bent slightly so that the liquid which drops from it will fall into the annular space in the alembic head.
L. DE K.

Measurement of Heats of Combustion with the Calorimetric Bomb and Platinum Resistance Thermometer. FRANZ WAGNE (*Zeitsch. physikal. Chem.*, 1910, 75, 81—94).—A number of other determinations of heats of combustion has been made by the method already described (Abstr., 1908, ii, 155). The heats of combustion in joules per gram are as follows: phenylacetic acid, 28.618; α -methyl glucoside, 18.175; naphthalene, 40.314; furoin, 23.941; glycine, 13.035; *DL*-alanine, 18.218; *D*-alanine, 18.217; *DL*-valine, 25.045; glycine anhydride, 17.441; *D*-alanine anhydride, 23.163; *DL*-leucyl-glycine, 24.367; formyl-*DL*-leucine, 24.134; diglycylglycine, 15.732; triglycylglycine, 16.119; glycylglycinecarboxylic acid, 11.234; methyl-uracil, 18.688; and isoserine, 13.709.

The sources of error in the work of previous observers, and the possibility of applying corrections to their data are discussed.

G. S.

Solutions. II. Variation of Density of Binary Mixtures with Temperature. F. SCHWERS (*Bull. Soc. chim.*, 1910, [iv], 7, 937—940).—In previous papers (Abstr., 1909, i, 80, ii, 794) it has been shown that if changes of volume are expressed in percentages of the initial volume, the volume-temperature curve for a binary liquid mixture is sinuous and shows characteristic inflexions. It can be superposed on that illustrating the relationship between refractive index and temperature for the same mixture (this vol., ii, 913), and is similar in form to the curve expressing the relationship between heat developed and temperature of admixture, for the same mixture. These observations cannot be explained by the hydrate theory of solutions, and the following explanation is suggested. Admixture of two liquids may cause disintegration of associated molecules, the existence of which was proved by Ramsay and Shields (*Trans.*, 1893, 63, 1089). Such disintegration causes, according to van Laar (Abstr., 1900, ii, 189), a diminution in volume. In a mixture this may be counterbalanced in part, or overbalanced, by an increase in volume due to a new association between different molecules. In raising the temperature of such a system, each complex formed will undergo disintegration in accordance with its own constant of dissociation, and since this constant is not a linear function for a single liquid, it is conceivable that such changes occurring in a mixed system may be represented by a sinuous curve.

T. A. H.

New Theory of Molecular Volumes. GERVAISE LE BAS (*Chem. News*, 1910, 102, 226—229).—The volumes of a number of atoms or groups in straight chain compounds or in the side chains of ring compounds have been calculated as described in previous papers compare Abstr., 1907, ii, 754; 1908, ii, 667). The results are as follows: OH = 11.1 = 3H; CO·OH = 37.0 = 10H; CO₂ = 33.3 = 9H; NO = 22.2 = 6H (except in CO·OH group, where CO = 25.9 = 7H); HO = 25.9 = 7H. Oxygen in the hydroxyl group generally, in the phenolic ethers, and in aldehydes and ketones = 2H; in the carbonyl group and in the aliphatic ethers it is equal to 3H. Doubly linked oxygen in a ring is also equal to 3H.

The volumes of a number of ring compounds containing oxygen are tabulated, and it is shown that ring structure is accompanied by considerable contraction, which varies in magnitude with the size and complexity of the ring. The relative volumes are, however, the same in spite of the contraction.

G. S.

Method for Determining the Lower and Upper Limits of Elasticity. The Hardening of Metals. O. PAUST and GUSTAV FARMANN (*Zeitsch. physikal. Chem.*, 1910, 75, 108—126).—The lower limit of elasticity of a metal can be determined by subjecting a piece of which one side is highly polished to pressure or to a pull, and observing microscopically the point at which the polish just begins to disappear. The elasticity can be increased by alternately slowly

increasing the pressure beyond the first limit of elasticity, and then releasing, until finally an upper limit of elasticity, corresponding with the limiting pressure which produces flow in the metal, is reached. The metal has, therefore, been hardened by slowly increasing the pressure. Some of the data for the lower and upper limits of elasticity are as follows: lead, lower limit 25 kilog./cm.², upper limit 102 kilog. cm.²; zinc, drawn, lower limit 75, upper limit 770 kilog./cm.²; copper, drawn, lower limit 1200, upper limit 2780 kilog./cm.². The lower limit depends greatly on the previous treatment of the sample.

* The hardening of metals is ascribed, not to formation of a harder crystalline form, or to a change to the amorphous condition, but to a diminution in the size of the crystallites of which the metal is composed, owing to the formation of systems of sliding surfaces. The hardening is, therefore, a preparation for flowing, the latter occurring when the systems of sliding surfaces have sufficiently increased. Detailed evidence in favour of this view of hardening is advanced.

G. S.

Viscosity of Isodynamic and Motoisomerides. FERDINAND B. THOLE (*Zeitsch. physikal. Chem.*, 1910, 74, 683—686).—Mühlenthein (*Dissertation*, Cöthen, 1907) has found that the densities and viscosities of nitrobenzene and of quinoline altered on keeping, and ascribed this result to the existence of these compounds in two isomeric forms. The author has prepared pure specimens of these compounds, and finds no difference in the viscosities or densities immediately after distillation, and after twenty-two hours. For nitrobenzene, D_4^{25} 1.1987, viscosity at 25° = 0.018224; for quinoline, D_4^{25} 1.08994, viscosity = 0.033724.

The statement of Schaum (*Abstr.*, 1898, i, 629) that the density of ethyl acetoacetate alters when kept is confirmed; the viscosity alters in a corresponding manner. The viscosity of the diethyl derivative of this ester, which cannot have an enolic constitution, and of ethyl malonate did not alter on keeping.

G. S.

Viscosity of Albumin Solutions. LEONOR MICHAELIS (*Biochem. Zeitsch.*, 1910, 23, 353—354).—Polemical against Pauli and Wagner (this vol., ii, 830). The author maintains the validity of his measurements of the isoelectric point.

G. S.

Influence of Chemical Affinity in Certain Adsorption Phenomena. LÉO VIGON (*Compt. rend.*, 1910, 151, 673—675; *Bull. Soc. chim.*, 1910, [iv], 7, 985—988. Compare this vol., ii, 273, 275, 692).—The phenomena of adsorption may be divided into two classes: those due to attraction between chemically inert substances in colloidal solution or in suspension, and those due to chemical affinity between two substances, one of which is insoluble whilst the other is in true solution, or between two insoluble substances having some degree of chemical activity. Thus inert compounds, like calcined silica or asbestos, have no attraction for picric acid in aqueous solution, whilst in the case of zinc oxide or aluminium hydroxide the acid is adsorbed. Quartz adsorbs the alkali hydroxides or carbonates, but not the

chlorides of sodium or magnesium. Brigg's results (Abstr., 1906, ii, 13) are discussed from this point of view. W. O. W.

Adsorption of Gases by Charcoal. ALEXANDER TITOFF (*Zeitsch. physikal. Chem.*, 1910, 74, 641—678. Compare Homfray, this vol., ii, 771).—The adsorption of hydrogen, nitrogen, carbon dioxide, and ammonia by coconut charcoal has been measured between -79° and $+151.5^{\circ}$ by the usual method. Between -80° and $+80^{\circ}$ the adsorption of hydrogen follows Henry's law, while the behaviour of the other gases at constant temperature is represented by the familiar formula $a_t = ap_t^{1/n}$, where a_t represents the amount of gas adsorbed at the pressure p_t , and a and $1/n$ are constants. When both pressure and temperature are varied, the results are represented by the formula $\log a_t = \log a_0 - (x - y \log p)/t$, where x and y are constants bearing a simple relationship to a and $1/n$. Deviations from these formulæ occur in the cases of carbon dioxide and ammonia at the higher pressures, under which conditions the gases are probably partly liquefied. Ammonia was adsorbed to the greatest extent; at 0° and 10 cm. pressure, 1 gram of charcoal adsorbed 71 c.c. of this gas.

The heats of adsorption, q , of nitrogen, carbon dioxide, and ammonia gases were determined by means of an ice calorimeter. The mean values of q at 0° for 1 c.c. of gas are as follows: nitrogen 0.203 cal., carbon dioxide 0.31 cal., and ammonia 0.386 cal., each about 50 cm. pressure, the results for the last two gases being in good agreement with those obtained by Chappius (Abstr., 1883, 702). The values of q diminish considerably with increasing pressure. The heats of absorption have also been calculated from the isothermal adsorption curves by means of the formula $-q = nRT^2(x \times y \log p)/22.4 \log e$, and there is fair agreement between the calculated and experimental values. G. S.

Absorption of Gases by Charcoal. IDA F. HOMFRAY (*Zeitsch. physikal. Chem.*, 1910, 74, 687—688. Compare this vol., ii, 771).—A few slight corrections to the former paper (*loc. cit.*) and some additional references are given. G. S.

Adsorption of Solutions [by Charcoal]. GERHARD C. SCHMIDT (*Zeitsch. physikal. Chem.*, 1910, 74, 689—737. Compare Abstr., 1895, ii, 39).—In the great majority of the experiments the adsorption of acetic acid from aqueous solution was studied. The rapidity with which equilibrium is established depends on the nature of the charcoal; with some specimens it is practically instantaneous at room temperature. At low temperatures, the equilibrium is reached very slowly; increase of temperature enormously accelerates the adsorption. This is due, at least in part, to the more rapid removal of gases adsorbed (chiefly air) in the fine pores of the material as the temperature is raised. When equilibrium is attained, and the solution then diluted, the new equilibrium point is rapidly reached, the rate being the greater the more the concentration is altered. If, on the other hand, a more concentrated solution is added to a system already in equilibrium, the new equilibrium point is only slowly attained.

It is shown by experiments with acetic acid in aqueous solution

that on gradually increasing the concentration a maximum of adsorption is reached, a fact which shows that the usual adsorption formulæ cannot be valid within wide limits. A new formula, $\log[S/(S-x)] - Ax = C(a/v)$, is derived, S representing the maximum of adsorption, x the amount adsorbed, a the total amount of the solute, v the volume, and A and C are constants depending on the amount and nature of the coal. This formula represents the experimental results fairly satisfactorily. There are, therefore, three determining factors in adsorption: S , the maximum adsorption, K (proportional to C), the activity coefficient of the material, and A , which is a measure of the falling off in the attraction between adsorbing surface and solute as the amount adsorbed increases.

From experiments with iodine and acetic acid in chloroform solution it is shown that the amount of two dissolved substances adsorbed from a solution containing both is less than the sum of the amounts adsorbed separately. Further, when charcoal is in equilibrium with one solute, and a second is added, it partially displaces the first substance from combination.

Some experiments on the adsorption of acetic acid from solution in ethyl acetate are described. G. S.

Dissociation of Ferric Sulphate. MAX BODENSTEIN and TATSUO SUZUKI (*Zeitsch. Elektrochem.*, 1910, 16, 912—916).—The measurements of Wöhler, Plüddemann, and Wöhler (Abstr., 1908, ii, 290) of the partial pressure of sulphur trioxide in equilibrium with ferric sulphate gave values three or more times larger than those of Keppeler and D'Aus (Abstr., 1908, ii, 289). The authors have therefore repeated both sets of experiments, taking every precaution to avoid accidental errors, and have obtained results which agree very well with the original measurements in both cases. In Wöhler's method the total pressure of the mixture of sulphur di- and tri-oxide and oxygen evolved by the heated ferric sulphate is measured, and the partial pressure of the trioxide calculated from Bodenstein and Pohl's measurements of the equilibrium constant. It is shown that the gases really are in equilibrium, and that this method of calculation is therefore justified. On the other hand, in Keppeler's method of passing air or nitrogen over the heated ferric sulphate, although the partial pressure of trioxide found is independent of the velocity of the gas within the rather narrow limits tried, the ratio between the oxides of sulphur and the oxygen is not in agreement with Bodenstein and Pohl's measurements of the dissociation of sulphur trioxide; there is always too little trioxide. The deviation diminishes as the temperature rises. It appears therefore that the low results obtained in Keppeler's experiments are due to equilibrium not being established. If ferric sulphate dissociates directly into ferric oxide and sulphur trioxide, an excess of trioxide would be anticipated instead of a deficit, hence the mechanism of the reaction is probably more complicated. T. E.

The Theory of Transpiration, Diffusion, and Thermal Conduction in Rarefied Gases. MARYAN SMOLUCHOWSKI (*Bull. Acad. Sci. Cracow*, 1910, 7A, 295—312).—The paper consists of three

sections. The first and second are concerned with a criticism of Knudsen's recent papers on the dynamics of rarefied gases (Abstr. 1909, ii, 216; *Ann. Physik*, 1910, 31, 205, 633) from the theoretical standpoint. It is stated that the treatment of the problems is invalidated by the neglect to take into account the modification of the Maxwell-Boltzmann law of distribution of velocities during thermal conductivity and diffusion. An expression is deduced for the increase of thermal conductivity of gases produced by molecular surface currents. An analysis for the condition of low pressure, where the mean free path of the molecule is large compared with the dimension of the vessel, leads to results somewhat similar to those of Knudsen, but, it is claimed, by a simpler and more rigorous method. The last section contains a discussion of the experimental results of Soddy and Berry on the conduction of heat through rarefied gases (this vol. ii, 180). An exact calculation of the theoretical conduction of heat gives as the result that their values should be multiplied by the factor $\sqrt{\pi/6} = 0.7236$, and by the term $1 - \beta + \beta$, where β is a coefficient representing the fraction of the total number of molecules "reflected" from the surface without change of kinetic energy. A recalculation of their results shows that β can never be neglected, the interchange of energy between the surface and the molecule impinging upon it being the less perfect the lighter the molecule and the greater its intramolecular energy. F. S.

Methods of Investigation of Capillary-chemical Problems. P. N. Fawcett (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 265—267).—From a consideration of surface-energy relationships, von Weimarn arrived at the conclusion that a substance in a very fine state of subdivision should melt at a higher temperature than that found for the substance in the form of coarse particles. Since this conclusion is contradicted by experiment, some doubt has been thrown on the validity of the deductions made on the basis of surface-energy considerations. The author points out that the conditions under which a melting-point determination is carried out in the ordinary way preclude the possibility of observing the effect which is to be expected on the basis of Laplace's theory of capillarity.

von Weimarn's views relative to the nature of the surface layer of crystalline substances are also criticised. The assumption that the properties of the surface layer approximate to those of the inner layers of a highly compressed liquid is tantamount to the view that the surface layer is isotropic, whereas the geometric and physical characteristics of crystalline substances indicate that the surface layer is anisotropic (compare this vol. ii, 1033). H. M. D.

Osmotic Equilibrium between Two Fluid Phases. L. GAY (*Compt. rend.*, 1910, 151, 754—756. Compare this vol. ii, 935).—The mathematical considerations advanced in a previous paper lead to the proposition that for two fluid phases in osmotic equilibrium with a common constituent at infinite dilution, at the same temperature and pressure, the variations in volume and thermal effects should be equal.

whatever the temperature and pressure. Some theoretical consequences of this conclusion are discussed in the present communication.

W. O. W.

Diffusion [of Dissolved Substances]. OSCARRE SCARPA (*Novo Cimento*, 1910, [v], 20, 212—225).—Vanzetti (Abstr., 1908, ii, 29, 88; 1909, ii, 978) has compared the coefficient of diffusion of certain electrolytes by allowing them to diffuse towards each other in a capillary tube filled with distilled water, and finding (for example, with silver nitrate and alkali chlorides) where a precipitate begins to appear. The author has deduced an equation which permits of the calculation of the coefficient of diffusion of one of the electrolytes in terms of that of the other, of the concentrations of the two electrolytes, and of the position in the tube where the precipitate begins to form.

It is shown that some of the assumptions of Vanzetti, for example, that the distances traversed by the salts are proportional to the coefficients of diffusion, are untenable. The values of the diffusion coefficients obtained by the above method agree neither with the theoretical values nor with those determined by the standard methods; the method is therefore not adapted to the study of diffusion.

The suggestion of Vanzetti that certain of his results are due to the hydrolysis of sodium chloride and other salts in very dilute solution is shown to be untenable. An equation is given which permits of the calculation of the hydrolysis of a salt of a strong base and a strong acid, and it is shown that the degree of hydrolysis is almost independent of the dilution, and therefore the quantity of salt hydrolysed diminishes with dilution, whereas Vanzetti has assumed that it increases.

G. S.

Fundamental Law for a General Theory of Solutions.

EDWARD W. WASHBURN (*J. Chim. Phys.*, 1910, 8, 538—568. Compare this vol., ii, 391).—The interdependence of the colligative properties of solutions (osmotic pressure, b. p., f. p., vapour pressure, etc.) follows from the laws of thermodynamics, and has no bearing on the question of the actual condition of solvent and solute. An ideal solution is one in which neither association nor dissociation of the solute nor association of solute with solvent (solvation) occur. In dilute solutions the molecular concentration of the solute is unaffected by solvation, so that dilute solutions of substances which neither associate nor dissociate behave as ideal solutions. The author develops the following general equation of state for solutions, which, whilst closely related to that advocated by van Laar, is expressed in terms of colligative properties rather than thermodynamic potentials: $d\pi = (-RT/V)\log N$, where π is the osmotic pressure, V the molecular volume, and N the molecular concentration of the solvent.

Physical properties in ideal solutions or mixtures are additive. The vapour tension of any volatile component, such as the solvent $p = p_0 N$, where p_0 is the tension of the pure component. This rule is known to hold in the case of many mixtures of analogous organic substances, such as were examined by Young (Trans., 1903, 83, 68).

Somewhat complex expressions are deduced for freezing point, boiling point, and the effects of concentration and temperature on chemical equilibrium in ideal solutions.

These laws of ideal solution apply to dilute solutions and to certain liquid mixtures, but in most concentrated solutions they are set aside by the unknown factors of association, and dissociation. R. J. C.

A Simple Method of Measuring the Affinity between the solvent and the Dissolved Substance. P. P. VON WEIMARN *J. Russ. Phys. Chem. Soc.*, 1910, 42, 646—647).—If a solvent Y contains in solution the substances $X_1, X_2, X_3, \dots, X_k$, the solutions being of considerable and equal concentrations, and another solvent Z , completely miscible with Y , but practically not dissolving $X_1, X_2, X_3, \dots, X_k$, be added, these substances will be precipitated when sufficient of Z has been added, and the more affinity the dissolved substance bears to Y the more of Z will be necessary. Thus the quantity of Z necessary to completely precipitate X_1, X_2, \dots, X_k from unit value of Y solution will be a measure of the affinity X_1, X_2, \dots, X_k bears to Y . The method has been applied to the solutions of various salts, etc. Z. K.

Partition Law in Mixed Solvents. II. WALTER HERZ and ALFRED KURZER (*Zeitsch. Elektrochem.*, 1910, 16, 869—872).—In addition to the cases previously studied (this vol., ii, 399), the partition of boric acid between water and mixtures of amyl alcohol and carbon disulphide, of iodine between chloroform and mixtures of water and glycerol, of bromine between water and mixtures of carbon tetrachloride and carbon disulphide are investigated. The partition constants for mixtures of two solvents usually differ from the values calculated from the constants of the pure constituents in the sense that the solute is less soluble in the mixture. Two more complicated cases (the partition of picric acid between water and mixtures of chloroform and toluene, and that of iodine between a solution of ammonium iodide and mixtures of carbon disulphide and carbon tetrachloride) are also examined, and found to follow the same laws which hold for single solvents. The results in the second case indicate the existence of BaI_4 molecules in the aqueous solution. T. E.

Diminution of Velocity of Crystallisation by Addition of Foreign Substances. HERBERT FREUNDLICH (*Zeitsch. physikal. Chem.*, 1910, 75, 245—256).—On the basis of the experimental data of von Beckardt (*Abstr.*, 1903, ii, 66) and of Padoa and Galeati (*Abstr.*, 1904, i, 714), it is shown that the diminution in the maximum velocity of crystallisation of supercooled liquids due to the addition of foreign substances is represented by the formula $G_0 - G = kc^{1/n}$, where G_0 is the velocity of crystallisation of the fused solvent, G that of the solution, c is the concentration, and k and n are constants; $1/n$ usually lies between 0.2 and 0.7. This can be accounted for on the assumption that the solvent is adsorbed at the crystal faces, and that the diminution in the velocity of crystallisation is proportional to the amount adsorbed (compare Mare, *Abstr.*, 1909, ii, 983). G. S.

Crystallisation of Agar-agar and Gelatin in Connection with the Mechanism of Gelatinisation. P. P. VON WEIMANN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 653—657).—The author rejects the generally accepted theory that solutions of gelatin, agar-agar, albumin, or other high molecular compounds are disperse systems, liquid α liquid, which are termed emulsoids, and that the gelatinisation of these systems is merely a separation of the two liquids into layers. The solution of such high molecular substances must, on the contrary, be regarded as true solutions, and their gelatinisation as being identical with the process of crystallisation. To obtain emulsoids and suspensoids, a solid substance X is dissolved in a solvent A , and another solvent B , which is miscible in all proportions with A , but does not dissolve X , is added. If the solution is concentrated, the addition of B will at first cause the formation of an emulsion, which will rapidly separate into two layers, X soon crystallising from the layer of A containing it. If a large volume of B is added and the mixture stirred vigorously, X may separate at once. If, however, a fairly dilute solution of X in A is taken, then the addition of B will produce a more stable emulsion and emulsoid, which will only crystallise after very long standing, and the crystals may be microscopic, ultramicroscopic, or even smaller, whilst if the solution is very dilute, the addition of B will at once produce a stable suspension and suspensoid. These considerations have been verified by experiments with manganese sulphate, lithium chromate, potassium carbonate, hydrogen carbonate, and formate, A being water, B an alcohol. With slight modifications, similar experiments with agar-agar and gelatin gave the same results. To obtain a partial precipitation of agar-agar and gelatin the suspensoid was alternately boiled and cooled, alcohol being added to replace that lost by evaporation. The precipitate thus obtained consisted of very minute, long, crystalline grains rounded at the edges.
Z. K.

Behaviour of Salts of Organic Acids on Melting. DANIEL VORLANDER (*Ber.*, 1910, 43, 3120—3135).—In previous papers (*Abstr.*, 1906, i, 317; 1907, ii, 70, 337, 441, 412; 1908, i, 641; ii, 22, 83) attention has been directed to the connexion between the chemical constitution of substances and their power of forming liquid crystals, and in the present paper this investigation is extended, and it is shown that liquid crystals are formed by salts of aliphatic and aromatic acids and by metallic derivatives of phenols, but not by aliphatic hydrocarbons, acids, esters, alcohols, or ketones.

The liquid crystals belong to the same system as those described previously (*Abstr.*, 1908, ii, 88). The salts of the optically active acids are not pleochroic, but certain of them show a play of colours in the liquid crystal state (compare *Abstr.*, 1908, i, 611). The formation of liquid crystals is shown to depend on polarity of structure in the molecule, and their stability and capacity for growing in the direction of the principal axis is due mainly to intramolecular energy difference.

[With R. WILKE and M. E. HUTT.]—The sodium and potassium salts of the normal fatty acids from acetic to cerotic were examined.

and it was found that the property of forming liquid crystals begins with butyric acid and ends with stearic, cerotic acid forming "resinous crystals" in the case of the sodium salt, and doubtful "resinous crystals" in that of the potassium salt. A large number of salts with other metals, particularly for the lower acids, were also examined, and details of the behaviour of these on melting are given. Tetramethylammonium stearate forms a liquid crystal phase.

Sodium allylacetate is a good material for the demonstration of liquid crystals, and the sodium salts of undecylenic, elaidic, erucic, and other unsaturated acids also show this phenomenon.

[With M. E. HURN.]—The tendency to form liquid crystals is greatly influenced by the branching of the chain of carbon atoms, at least among the sodium salts of fatty acids; thus *isovaleric* and *isopropylacetic* acids yield sodium salts, which form liquid crystals, whilst *2-methylbutyric* and *di-2-methylpropionic* acids do not, but the potassium salts of all four show this phenomenon.

The alkali salts of the di- and tri-basic fatty acids do not give liquid crystals as a rule.

The alkali salts of the aromatic acids in many cases yield liquid crystals, but no general correlation with constitution can be deduced. Among substituted benzoic acids the salts of *ortho*-, *meta*-, and *para*-derivatives show equal facility in giving liquid crystals, but the *ortho*-compounds are usually *monotropic*, whilst the *isomeric meta*- and *para*-substances are *enantiotropic*.

Among phenols, only the potassium derivatives of *o*- and *p*-nitrophenol show the phenomenon.

In carrying out these investigations, great difficulty is experienced in observing the two melting points, and the use of the polarisation microscope with crossed Nicols is unadvisable, owing to the difficulty of observing the temperature. For substances of high melting point, Linne's heating apparatus, as constructed by Fuess, is used, and for substances of low melting point, a small melting tube with a stirrer of capillary glass tube or a platinum wire. Approximate first and second melting points for a long series of salts of organic acids, thus determined, are given in the original.

T. A. H.

Proof of the Movements of Dissolved Molecules Demanded by the Molecular Kinetic Theory. THE SVEDBERG (*Zeitsch. physikal. Chem.*, 1910, 74, 738—742).—In a previous paper (compare *ibid.*, vol. ii, 772) it has been shown that the movements of particles in a colloidal solution is such that the mean deviation from the average number of particles in a definite volume of solution corresponds with that required by the kinetic theory. The same is now proved to be the case for dissolved molecules as a result of experiments with a solution of polonium chloride. A small portion of the solution was covered with a screen coated with zinc sulphide, and the number of α -particles produced in a given time numbered by observing the impacts on the screen in the usual way. When allowance is made for the deviation from the mean owing to the irregular breaking-down of the radioactive atoms, it is found that the momentary differences of

concentration in a limited volume of a true solution correspond with the requirements of the molecular-kinetic theory. G. S.

[History of the Orientation Theory of Matter.] P. P. VON WEIMARN (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 256—265).—A historical account is given of the views which have been put forward at different times in reference to the nature of the "amorphous" state. Quotations are given from papers by Fuchs, Frankenheim, and Lehmann. H. M. D.

Coagulation of Colloids. V. A. VOLSCHIN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 863—876).—The non-agreement between the numbers obtained by various authors for the coagulating power of the same and analogous coagulating substances is probably due to the various methods employed for obtaining colloidal solutions, the different methods of experiment, and to the varying concentrations of the colloid investigated. To characterise the coagulating power of an ion by a number, it is necessary to investigate: (1) the connexion between the concentration of the coagulating ion and the concentration of the colloid precipitated. (2) Whether this relation is identical or not for ions of different valencies. (3) Whether this relation remains the same for different colloids. The present paper is the first of a series to determine these questions. Soluble Prussian-blue, $\text{Fe}_4[\text{Fe}(\text{CN})_6]_3$, as obtained directly by the interaction of ferric chloride and potassium ferrocyanide, and the insoluble blue,

in oxalic acid solution were used as colloids, and sodium, potassium and ammonium chlorides as coagulating electrolytes. The main portion of the latter was added from a burette to the colloid of given concentration, and the rest added in very small portions or drop by drop, a small portion of the mixture being withdrawn by a capillary pipette and examined under the microscope after each addition. The commencement of the coagulation could thus be accurately determined. Tables and curves are given showing the number of gram-mols. and concentration of electrolyte necessary to coagulate colloid solution of varying concentration.

The curve for each electrolyte is of exactly the same character, resembling the crystallisation curves in a mixture of two salts. It consists in each case of branches, the breaks coming at exactly the same points on the abscissæ (where are marked the total volume of colloid + electrolyte at coagulation point).

The ordinates (gram-mols. of electrolyte) corresponding with these points are in the ratio:

and these relations are true whatever the concentration of the colloid. Coagulation by means of electrolytes, although in some respects a purely physical phenomena, may yet exhibit laws characteristic of purely chemical processes, and this is particularly the case with the substances dealt with here. Z. K.

Filtration of Colloidal Solutions. A New Filter. A. SCHOEP (*Bull. Soc. chim. Belg.*, 1910, 24, 354—367).—The addition of a certain quantity of glycerol to an ethereal-alcoholic solution of cellulose nitrate increases the permeability of the collodion membrane made from such solutions. The membrane, however, is not stable on exposure to the air, as it contracts and glycerol is exuded. If castor oil is added as well as glycerol, a stable membrane is obtained, which does not contract on exposure to the air, and can be preserved for a long time between filter paper in order to keep away moisture. It can be used as an ultra-filter, which works under the pressure of the liquid contained in it, no extra pressure being necessary. To prepare it for use, it is simply soaked in water to dissolve out the glycerol. The solutions which gave the best membranes contained four parts of cellulose nitrate, 3.5 parts of castor oil, and 2.5, 3, 4, and 5 parts respectively of glycerol, the alcohol and ether used to form the solution being in the proportion 10 parts of alcohol to 80 parts of ether.

Experiments on the filtration of colloidal solutions, classified according to the size of the particles (compare Bechhold, *Abstr.*, 1908, ii, 24, 823), showed that the smaller the particles, the smaller is the amount of glycerol which should be used to obtain membranes which will retain the particles.

The membranes so made can only be used for the filtration of colloidal solutions containing particles varying in size from those of colloidal arsenic sulphide to colloidal Prussian-blue (compare Bechhold, *loc. cit.*). The author has succeeded in separating colloidal arsenic sulphide from Prussian-blue by filtration through the membrane containing 4 parts of glycerol to 4 and 3.5 parts of cellulose nitrate and castor oil respectively.

T. S. P.

The Action of Chloroform on Lipoid Suspensions. D. CALUGAREANU (*Biochem. Zeitsch.*, 1910, 29, 96—101).—The appearances are described when cholesterol and other lipoids in colloidal solution are shaken with chloroform and other solvents which are not miscible with water. The particles of the lipid increase in size, and in the case of cholesterol lose their crystalline form, and form a kind of precipitate on the surface of the chloroform when this solvent is employed in the experiment. The phenomenon is ascribed to the adsorption of the chloroform on the surface of the lipid, and is contrasted with the phenomena observed when colloidal metals, such as gold and silver, are shaken with mercury. Here no adsorption takes place, and the difference of action is ascribed to the fact that the mercury, in contrast to chloroform, is not soluble in water.

S. B. S.

The System Chlorine-Sulphur Dioxide. ANIRIAS SMITS and N. J. DE MOY (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 339—341).—The nature of this system has been investigated by freezing-point measurements. The melting points of chlorine and sulphur dioxide are -100.45° and -75.6° respectively. The data obtained in the dark indicate a eutectic point at -102.3° , the

composition corresponding with 1.5 mols. % of sulphur dioxide. From the form of the freezing-point curve, the authors conclude that mixed crystals are formed.

Measurements in which the mixtures were subjected to sunlight or the light from a quartz mercury lamp show that sulphuryl chloride is formed very rapidly in these circumstances. A mixture containing 47.1 mols. % of sulphur dioxide, in which equilibrium had been established in sunlight, was found to exhibit initial solidification at -80° , which is very much higher than the temperature corresponding with the freezing-point curve for the system in the dark.

H. M. D.

Critical End-Points in Ternary Systems. ANDREAS SMIT (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 342—352).—The gradual changes which the critical solution phenomena exhibit when a third substance is added to a binary system are discussed. The third substance is of such a nature that it does not yield critical end-points with either of the components of the binary system, and is completely miscible with these components in the liquid state. The binary system to which special reference is made is that of ethyl ether-anthraquinone, which has been previously examined in detail, and the third substance is ethyl alcohol.

H. M. D.

Critical Phenomena of the Ternary System Ethyl Ether. Anthraquinone, and Naphthalene. ADA PAIRS (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 353—359).—Experiments have been made to ascertain the nature of the critical solution phenomena which are exhibited when the binary system ethyl ether-anthraquinone is converted into a ternary system by the addition of naphthalene. For small quantities of naphthalene the two critical end-points, which are characteristic of the binary system, are still observable. As the proportion of naphthalene increases, the end-points approximate to one another, and the special region bounded by the critical curves disappears as a result of this approximation when the proportion of naphthalene added amounts to 4.5%.

H. M. D.

The Ternary Systems Alkali-Phosphoric Acid-Water. JON. D'ANS and O. SCHREINER (*Zeitsch. physikal. Chem.*, 1910, 75, 95—107).—The equilibria in these systems have been determined by solubility measurements at 25° in the usual way, and the results are given in tabular form, and also represented graphically.

In the system containing sodium salts, the solid phases met with were the compounds $\text{Na}_3\text{PO}_4 \cdot 12\text{H}_2\text{O}$, $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$, $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$, $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$. Trisodium phosphate dodecahydrate has a transition temperature at $70.75 \pm 0.1^{\circ}$. The corresponding disodium salt has two transition points, the first, represented by the equation $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O} \rightleftharpoons \text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O} + 5\text{H}_2\text{O}$, at $35.4 \pm 0.05^{\circ}$; the second, $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O} \rightleftharpoons \text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O} + 5\text{H}_2\text{O}$, at $48.35 \pm 0.05^{\circ}$. The solubility, in grams anhydrous salt per 100 grams of water, is 46.11 at the former, and 79.00 at the latter, transition point. The region of the acid mono-

sodium phosphate described by previous observers was not reached; it is stable only in the presence of practically pure phosphoric acid.

In the system containing potassium salts, only the three anhydrous salts, K_2PO_4 , K_2HPO_4 , and KH_2PO_4 , were met with. The investigation was difficult owing to the extremely high solubility of the di- and tri-potassium salts. The region within which K_2HPO_4 exists is very narrow, lying between the ratios $K : PO_4 = 6.9 : 4.15$ and $K : PO_4 = 4.8 : 1$, or $K : PO_4 = 1.66 : 1.60$. The region of the acid monosodium phosphate, KH_2PO_4 , H_3PO_4 , described in the literature was not reached.

In the system containing ammonium salts, the compounds $(NH_4)_3PO_4$, $3H_2O$, $(NH_4)_2HPO_4$, and $NH_4 \cdot H_2PO_4$, were met with as solid phases. The diammonium salt exists only within narrow limits of concentration.

For all three alkalis, the systems in which the solution and the solid phase have the ratio $PO_4 : \text{alkali} = 1 : 1$ represent an absolute minimum in the solubility of these compounds; in other words, the solubility of the monoalkali phosphates is increased by the addition of alkali as well as of phosphoric acid.

G. S.

Stability of the Two Crystalline Modifications of Phenol. GISELA TAMMANN (*Zeitsch. physikal. Chem.*, 1910, 75, 75—80).—The conditions of stability of the different forms of phenol have been further investigated (compare Abstr., 1909, ii, 983) by an improved experimental method.

As a preliminary to the preparation of phenol II (the denser modification) in open vessels at atmospheric pressure, curves are plotted giving the temperatures and corresponding pressures at which the velocity of transformation of phenol II to phenol I in the presence of both phases becomes appreciable. Further, the conditions under which spontaneous transformation of phenol II to phenol I (ordinary phenol) takes place are tabulated. At -39° , the latter change takes place at 154 kilog./cm.² pressure; at -28.2° , 410 kilog.; at $+3.5^\circ$, 1025 kilog., and at 29° , 1625 kilog. At -80° , no appreciable change takes place in a considerable time at atmospheric pressure.

Phenol II was prepared at 15° under a pressure of 3000 kilog./cm.². The cylinder of nickel steel containing it was then cooled at -80° , and the pressure gradually lowered to 1 kilog. After some further manipulations, phenol II was obtained, and freed from its wrappings in a mixture of light petroleum and chloroform cooled to -80° , in which it sank, whereas a piece of ordinary phenol floated in the mixture. The diminution of volume when phenol I changes to phenol II is 0.06 cm. per gram.

G. S.

[Temperature-coefficient of Chemical Reaction Velocities.] Correction. MAX TRAUZ (*Zeitsch. physikal. Chem.*, 1910, 74, 747).—A correction is applied to one of the author's formulae on this subject (compare this vol., ii, 24) which simplifies it and renders it more accessible to experimental investigation.

G. S.

Slow Combustion of Sulphur. MAX BODENSTEIN and WALTER KUHO (*Zeitsch. physikal. Chem.*, 1910, 75, 30—47).—Ewan (Abstr., 1895, ii, 213) found that the rate of oxidation of sulphur is proportional to

the square root of the pressure of the oxygen, but the present authors have obtained entirely different results.

The sulphur was heated at constant temperature (252°) with oxygen in a glass tube for definite intervals, the mixture of oxygen and sulphur dioxide transferred to a measuring vessel, and the proportion of sulphur dioxide in the mixture determined by observation of the pressure before and after absorption of the sulphur dioxide with an iodine-potassium iodide solution.

The rate of reaction is directly proportional to the pressure of the oxygen, and is roughly proportional to the surface of the sulphur. The rate increases in the ratio 1.87:1 for a rise of temperature of 10° . From these observations the conclusion is drawn that the controlling reaction is a chemical one, which takes place in the adsorption layer on the surface of the sulphur. The excellent agreement of the velocity coefficients shows that the sulphur dioxide, which must accumulate in the adsorption layer, has no influence on the reaction velocity, and the authors show that this can be reconciled with their view as to the mechanism of the reaction.

At 159° , the temperature at which Ewan worked, the rate of oxidation of sulphur is extremely slow, and this observer must therefore have measured some other reaction. His heated sulphur was near a soda-lime tube (used for absorbing the sulphur dioxide), and it is suggested that the sulphur distilled over to the soda-lime, forming polysulphides and thiosulphate, which were very rapidly oxidised by the oxygen.

G. S.

Specific Stereochemical Behaviour of Catalysts. KASIMIR FAJANO (*Zeitsch. physikal. Chem.*, 1910, **75**, 232—234. Compare this vol., ii, 599).—The point at issue between the author and Rosenthaler (this vol., ii, 232) requires further experimental investigation.

G. S.

Dead Spaces. RAPHAEL ED. LIESEGANG (*Zeitsch. angew. Chem.*, 1910, **23**, 2124—2125).—A small glass tube, open at both ends and filled with a 10% jelly containing sodium chloride, is immersed in a solution of silver nitrate. When the diffusion of the silver nitrate and the precipitation of silver chloride is complete, a clear space of several mm. is left in the centre of the tube, where no precipitation has occurred. It contains silver nitrate but no chloride. This "dead space" is due to the fact that the sodium chloride has diffused away to the places where precipitation of silver chloride has occurred. Such a "dead space" is not formed when the substance dissolved in the jelly is not diffusible, for example, when the jelly contains albumin and the tube is immersed in metaphosphoric acid.

If the jelly contains potassium dichromate instead of sodium chloride, a "dead space" is still formed in the middle of the tube. The silver chromate deposit is not continuous, however, as in the case of silver chloride, but in the form of rings with clear spaces between (the ordinary Liesegang phenomenon). The latter clear spaces are not identical with the "dead space" in the centre of the tube, if a "dead space" is defined as one where no chemical reaction has taken place,

since silver chromate has been formed in them, and while in supersaturated solution has diffused to the places where precipitation has taken place. These results make it doubtful whether the phenomena observed by Liebreich (Abstr., 1891, 1150) are really due to the occurrence of "dead spaces."

The importance of these phenomena in connexion with, for example, the occurrence in many bones of zones poor in lime is pointed out.

T. S. P.

Repeating Figures in the Atomic Weight Values. F. H. LORING (*Chem. News*, 1910, 102, 228—229).—In the International Tables for 1911 there appears to be a tendency for the figure in the unit's place to recur in the second place of the decimals, for example, Ag = 107.87, Fe = 55.85, but this may be accidental.

G. S.

A New Valve. AUG. KUMM (*Chem. Zeit.*, 1910, 34, 1136).—A valve for preventing the return of water into vessels while being exhausted by the filter-pump is described. A glass rod is supported on the mouth of a vertical glass tube by means of an expansion covered with indiarubber. During suction the valve is raised, but if the pump is stopped, or if water returns, the rubber-covered expansion makes a tight joint with the tube.

C. H. D.

Modified Drying Tube. EDWIN DOWZARD (*Amer. J. Pharm.*, 1910, 82, 509—510).—By inserting a stopcock in the lower part of a Pelligot drying tube, the exhausted sulphuric acid may be removed and replaced with fresh acid by suction at the side-tube without dismantling connected apparatus. A small test-tube is suspended under the stopcock to catch drops of exuding acid.

T. A. H.

Extraction Apparatus. R. P. NOBLE (*J. Amer. Chem. Soc.*, 1910, 32, 1533).—A form of apparatus for the extraction of substances by means of mixed solvents is described. It consists of a glass tube, the bottom of which is connected with a syphon tube, to the upper end of which a side-tube is attached. The substance to be extracted is contained in a cartridge, and the solvent is removed by actuating the syphon. The apparatus avoids the use of any stopcock.

H. M. D.

Lecture and Laboratory Apparatus. JAMES A. SCHOFIELD (*Austral. Assoc. Report*, 1909, 167—172).—The following forms of apparatus are described. I. Apparatus for showing the composition of nitrous and nitric oxides. Instead of the original method devised by Davy for heating sodium in the gas, the sodium is contained in a deflagrating spoon and fired electrically. The gas is confined in one limb of a manometer, the electrical connexions passing through a rubber cork at the top of the tube. II. Apparatus for the preparation of ammonium hydroxide solution, concentrated and dilute, from liquid ammonia. III. A rapid form of condenser for distilled water. The condenser is practically a reversed tubular boiler, nine $\frac{3}{4}$ -in. tin tubes 1 ft. long forming the condenser. IV. A cheap demonstration balance. Fitted to the centre of the beam, and projecting above it, is a light aluminium

pointer, about 21 inches long, playing over a cardboard scale. The scale and pointer are turned towards the class, the ordinary scale and pointer being towards the lecturer. The aluminium pointer is counter balanced by a binding screw clamped on to the ordinary pointer. V. Nickel crucibles for the Laurence Smith method of determining alkalis in silicates. These crucibles are used for the decomposition of silicates with calcium carbonate and ammonium chloride, and give the same results as platinum ones.

T. S. P.

Apparatus for Laboratories and Lecture Experiments. JOHANNES THIELE (*Annalen*, 1910, 376, 279—285).—Chlorinations and brominations, and also the detection of feeble fluorescence, can be accomplished very successfully in the light of an arc lamp instead of in sunlight. Apparatus for the demonstration of the production of water in quantity from its elements and of the combustion of nitrogen are described, and also electrically heated filter funnels, boiling point apparatus, etc.

Many lecture experiments, in which the reagents are heated to boiling, can be performed in very much shorter time by placing a little of the not too dilute reagents in an upright cylinder and adding much boiling water. The hydrolysis of ferric alum, the formation and decomposition of copper hydride, the hydrolysis of carbonates and of sucrose, the decomposition of mercuric nitrate, and the hydrolysis of ferric chloride are thus readily demonstrated.

G. S.

Inorganic Chemistry.

Preparation of Pure Hydrogen Peroxide for Medical Purposes. OTTO SCHMATOLLA (*Pharm. Zeit.*, 1910, 55, 888—890).—The method used consists essentially of (1) solution of commercial barium peroxide in hydrochloric acid, phosphoric acid being added to precipitate metals such as iron; (2) precipitation from the solution of hydrated barium peroxide by means of sodium hydroxide; and (3) preparation of the solution of hydrogen peroxide in the usual way by the addition of the hydrated barium peroxide to sulphuric acid.

T. S. P.

Formation of Hydrogen Peroxide. K. V. CHARITSCHOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 900—904).—Papers prepared with cobalt naphthenate are very sensitive to hydrogen peroxide, turning from pink to olive-green (compare this vol., ii, 238). In bright sunlight or by a rise of temperature they become still more sensitive, it being possible to detect one part in 1,000,000 of water.

Water containing oxygen when exposed to bright sunlight gives the hydrogen peroxide reaction after the following intervals: at 9—22° after twelve days; 19—31° after eight days; 20—41° after seven days.

If the oxygen is replaced by air, no hydrogen peroxide is formed. In similar experiments with radioactive barium chloride, and also the nitrates of barium, lead, thorium, uranium, and bismuth, hydrogen peroxide was formed only in the presence of radioactive barium salt and of lead nitrate. When, however, the experiment was made in the dark, even radioactive barium produced a negative result; it is therefore considered that it is not the radium emanation which induces the reaction $2\text{H}_2\text{O} = \text{H}_2\text{O}_2 + \text{H}_2$, but that the radium salt acts as a catalyst.

Hydrogen peroxide is also formed on the surface of moist, porous substances, such as wood, asbestos, and so forth. Z. K.

Formation of Hydrogen Peroxide in the Combustion of Detonating Gas. K. V. CHARITSCHKOFF and AMBARDANOFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 904).—Using the cobalt naphthenate papers (compare preceding abstract), hydrogen peroxide was detected in the products of combustion of detonating gas, 0.000476 c.c. hydrogen peroxide being produced from the combustion of about 25 litres of hydrogen in oxygen.

Hydrogen peroxide could not be detected in the combustion of benzene or of alcohol. Z. K.

Colour of Iodine Solutions. JOEL H. HILDEBRAND (*Zeitsch. physikal. Chem.*, 1910, 74, 679–682).—The author answers some adverse criticisms of Waentig (this vol., ii, 117) on his and Glascock's work on this subject (compare Abstr., 1909, ii, 225). In particular, the standard solution (for comparison purposes) was prepared by adding to the violet solution of known iodine concentration sufficient of the "active" solvent to be investigated to change the violet colour completely to brown, so that Waentig's objection that the authors had assumed the colour of the additive compound to be the same for all the solvents used is not valid. G. S.

Solubility of "Insoluble" Sulphur (S_{μ}). ALBERT WIGAND (*Zeitsch. physikal. Chem.*, 1910, 75, 235–244. Compare Abstr., 1910, i, 228).—When amorphous insoluble sulphur, S_{μ} , is treated with carbon disulphide or carbon tetrachloride, a small proportion of it (usually not exceeding 3 per cent. with carbon disulphide) goes into solution, the proportion depending on the time of action, the temperature, and the nature of the solvent, but being independent of the amount of solvent. This is ascribed to a partial change of S_{μ} to soluble sulphur, S_A , under the influence of the solvent. Further, a small amount of S_{μ} , under ordinary conditions less than 1 in 1000, goes into solution unaltered, probably in the colloidal form.

The author maintains the accuracy of his figure, 118.95, for the melting point of monoclinic sulphur. G. S.

The Supposed Nitrososulphonic Acid of Raschig (Sabatier's Nitrosodisulphonic Acid) and the Theory of the Lead Chamber Process. WILHELM MARCHOT (*Zeitsch. angew. Chem.*, 1910, 23, 2113–2114).—Raschig's theory of the lead chamber

process assumes the intermediate formation of nitrososulphonic acid, $\text{HO}\cdot\text{NO}\cdot\text{SO}_3\text{H}$ (compare Abstr., 1908, ii, 30), the solution of which in concentrated sulphuric acid has a blue colour; in more dilute acids there is a slight red colour. This blue colour is also produced by the action of a mixture of sodium nitrite and mercury on sulphuric acid, but disappears after a time, nitric oxide being evolved.

The author finds that the solution of nitric oxide in pure sulphuric acid is colourless; if, however, the sulphuric acid contains iron, a red coloration is produced. The red coloration observed by Raschig in some experiments of his (Abstr., 1905, ii, 23, 700), and also a solubility of nitric oxide in sulphuric acid considerably greater than that observed by the author, are due to the use of impure sulphuric acid. The "purple acid" from the Gay Lussac tower is nothing more than a solution of the ferrous or ferric sulphate compound of nitric oxide.

The brown coloration produced by the solution of nitric oxide in an aqueous solution of ferrous sulphate is not due to the formation of

ferrous nitrososulphonate, $\text{ON}\langle\begin{smallmatrix} \text{O} \\ \text{SO}_3 \end{smallmatrix}\rangle\text{Fe}$, as assumed by Raschig,

since the same colour is produced with ferrous chloride and ferrous hydroxide. The compounds formed contain one molecule of nitric oxide to one atom of iron, and are probably of the type $\text{NO}\cdot\text{FeCl}_2$ (compare Abstr., 1907, ii, 93). For similar reasons it is probable that Raschig's copper nitrososulphonate does not exist (compare this vol., ii, 956).

Thus the existence of a nitrososulphonic acid has still to be proved. The same objections may also be raised to Sabatier's nitrosodisulphonic acid.

T. S. P.

Revision of the Atomic Weight of Nitrogen. Exact Analysis of Nitrogen Tetroxide. PHILIPPE A. GUYE and C. DROUJININE (*J. Chim. Phys.*, 1910, 8, 473—514).—The atomic weight of nitrogen has been determined by decomposing weighed quantities of nitrogen tetroxide with incandescent iron wire.

The possibility of obtaining pure nitrogen tetroxide for the purpose depends on the following considerations. Nitrogen trioxide is easily oxidised at the ordinary temperature to tetroxide. The tetroxide is not further attacked by oxygen, although it is oxidised by ozone; on the contrary, the pentoxide undergoes spontaneous decomposition into tetroxide and oxygen. The equilibrium between nitrogen tetroxide and nitric oxide plus oxygen has been determined, and the result shows that the dissociation of tetroxide is negligible under the conditions of experiment. The calculations are not affected by the question as to whether the formula of the tetroxide is NO_2 or N_2O_4 . The vapour-pressure curves of nitric oxide, nitrogen tetroxide, and nitrogen trioxide (prepared by Baker's method) were determined in an apparatus specially designed to protect the surface of the mercury by a buffer of air from corrosion by the tetroxide. The curves, which are in accord with those of Ramsay and Young, indicate that although the tetroxide should be easily separated from nitric oxide by distillation, the removal of trioxide would be difficult. Accordingly, the tetroxide was prepared by mixing purified and carefully dried nitric oxide with

excess of purified oxygen, and was distilled in a vacuum at least ten times in presence of free oxygen, precautions being taken to free the final product from dissolved oxygen. The absence of traces of trioxide was inferred from the colourless nature of the liquid product. Throughout the manipulations, phosphoric oxide was used to exclude moisture.

The decomposition apparatus consisted of an oval bulb placed with its major axis horizontal, and provided with a stopcock at the top and a tubulure for condensing the gas at the bottom. A spiral of iron wire which traversed the bulb could be heated electrically. It was prepared for use by alternate oxidation and reduction in a low pressure current of dry hydrogen.

From one to two grams of dry nitrogen tetroxide of f. p. -9.6° were distilled into the bulb, and solidified in the tubulure by a freezing mixture. The bulb, having been evacuated and closed, was allowed to warm up, and weighed. After passing the current and removing the residual nitrogen by the pump, the bulb was weighed again.

The mean of seven determinations gives 14.010 as the atomic weight of nitrogen, or neglecting the two first determinations, the remaining five give a mean value 14.009 ($O=16$). Considering the possible sources of error, the atomic weight could not be less than 14.005, and probably not less than 14.008.

The values obtained are in good agreement with those deduced from analyses of nitrous oxide by Guyot (14.0107) and analyses of nitric oxide by Gray (14.0097), but are opposed to those recently calculated by Richards from analyses of silver nitrate, namely, 13.990 to 14.002. The authors consider that the various direct measurements of nitrogen-oxygen ratios are more trustworthy and agree better amongst themselves than the indirect (silver) values, and that it would be reasonable to make the atomic weight of silver depend on the directly determined value for nitrogen, since this is supported by the physical constants of nitrogen.

R. J. C.

Formation of Nitric Oxide in the High Tension Arc.
FRITZ HABER, ADOLF KOENIG, and E. PLATOU (*Zeitsch. Elektrochem.*, 1910, 16, 789—796).—The apparatus and method of experiment have been described in previous papers (Abstr., 1908, ii, 34, 940). Two sets of experiments were made. In the first set, the length of arc and the current (0.27 ampere) were kept constant, and the pressure of the air varied. The results show a very decided maximum yield at 150 mm., the gas leaving the arc containing 8.16% of nitric oxide at this pressure. The second set was designed to determine the relationship between the energy consumed in the arc and the quantity of nitric oxide produced. Owing to the distortion of the voltage curve by the discharge through the gas, the curves of voltage and current are not in the same phase, which introduces some difficulty in the measurement of the energy used in the arc. The methods of measurement are described in detail. The best yield in twenty-four experiments with air at 140 mm. pressure was 57 grams of nitric acid per kilowatt-hour, with 3.4% of nitric oxide in the gas leaving the arc.

T. E.

Formation of Nitric Oxide from Air by means of High Frequency, Alternating, Electrical Discharges. FRITZ HABER and E. PLATOU (*Zeitsch. Elektrochem.*, 1910, 16, 796—803).—The electrical measurement of the energy consumed in an unsteady arc produced by an high frequency, alternating current is impossible. The authors have, therefore, measured it by immersing the apparatus in which the discharge occurs in a calorimeter consisting of a Dewar's tube filled with paraffin oil. The platinum resistance thermometer also serves as a stirrer, and the hot gases leave the discharge tube through a silver tube filled with silver filings, which is immersed in the oil and serves to cool them. The discharge takes place between platinum wires placed closed together at their lower extremities and diverging at their upper ends. Good results are only obtained when considerable quantities of energy are used in the arc, and when it is well spread out in a fan-shape. With a current of about 500 periods per second, and air at atmospheric pressure, the yield is as high as 54 grams of nitric oxide per kilowatt-hour; with about one hundred times higher frequency, slightly worse results were obtained (48.7 grams of nitric acid per kilowatt-hour), whilst diminishing the pressure to 387 mm. reduced the yield to about 20 grams. The lower yields are, however, ascribed to the tendency of the arc to hang to one spot on the platinum wires instead of travelling along them, and the authors think that neither pressure nor frequency have any specific influence on the yield obtainable. T. E.

Yield of Nitric Oxide in the Combustion of Air in the Cooled, Direct-current Arc. WILHELM HOLWECH and ANTON KOENIG (*Zeitsch. Elektrochem.*, 1910, 16, 803—810).—An iron wire, 2 mm. diameter, surrounded by a quartz tube served as cathode. The anodes were water-cooled, copper capillary tubes of from 0.5 to 3 mm. bore. The electrodes were usually placed 2 to 5 mm. apart, and the air was drawn off through the capillary tube by means of an air pump; the arc is thus drawn into the cold capillary tube, and the greater part of its length, which varies with the rate at which the air flows, is within the tube. The cathode was not heated as in Holwech's experiments with the same arrangement (this vol., ii, 578), but this had no effect on the results. The yields are always better when the capillary anode is vertically below the cathode, and the air, therefore, drawn downwards, than it is when their positions are reversed. The yield increases with the velocity of the air current (the percentage of nitric oxide in the gas, of course, decreases); with the 0.5 mm. capillary a yield of 74.3 grams of nitric acid per kilowatt-hour was obtained, using air, with 1.94% of nitric oxide in the gas, the arc taking 0.29 ampere at 290 volts. The best results were obtained with the 2 mm. capillary tube, 84.8 grams of nitric acid per kilowatt hour being reached with 2.3% of nitric oxide in the gas, a current of 0.2 ampere, and 280 volts. Attempts to concentrate more energy into the arc gave worse results; reversing the poles and using alternating current also were less successful. T. E.

Formation of Nitric Oxide from Air in the Arc under Pressure. FRITZ HABER and WILHELM HOLWECH. (*Zeitsch. Elektrochem.*, 1910, 16, 810—813).—The arc is formed in a vertical steel tube between a cooled copper cathode and an iron anode placed respectively at the top and bottom of the tube. The air is blown in at the bottom tangentially to the walls of the tube. In one arrangement, cold air was used, in another it was heated by passing over the outside of the steel tube before entering it. With the first arrangement, 0.55 to 1.5 ampere at 700 to 2075 volts were used, and pressures varying from 2 to 21 atmospheres. The best yield was 76 grams of nitric acid per kilowatt-hour with 2 atmos. pressure and 0.36% of nitric oxide. The same yield was obtained at 11 atmos. with only 0.29% of nitric oxide in the gas. With pre-heated air, using currents of 0.5 to 0.6 ampere and 1200 to 1460 volts, the yields were better, 82.8 grams of nitric acid per kilowatt-hour being obtained with 4 atmos. pressure and 0.7% of nitric oxide. At higher pressures, the yields were rather lower.

T. E.

Formation of Nitric Oxide during the Combustion of Hydrogen. A. WOLOKITIN (*Zeitsch. Elektrochem.*, 1910, 16, 814—826).—The experiments of Haber and Coates (Abstr., 1909, ii, 997) on the formation of nitric oxide during the combustion of carbon monoxide in mixtures of oxygen and nitrogen are extended to hydrogen, using the same apparatus and methods of experiment. The results are very similar; the combustion of hydrogen in air at the ordinary pressure yields no nitric oxide; when the pressure is increased to 20 atmospheres or more, about 0.3 mol. of nitric oxide is formed per 100 mols. of water. With a mixture of equal volumes of oxygen and nitrogen, the yield is small at low pressures, but increases with the pressure, nearly 3 mols. of nitric oxide per 100 mols. of water being obtained at 15 atmos. pressure. Further increase of the pressure up to 50 atmos. produces but little further increase in the yield. A mixture of oxygen and nitrogen with 80% of the former behaves in much the same way as the mixture of equal volumes. The theoretical calculation of the yield, made in the manner adopted by Haber and Coates, indicates a maximum yield of about 4 mols. of nitric oxide per 100 mols. of water, using a mixture of equal volumes of oxygen and nitrogen; the actual yields are less than the theoretical ones, whereas Haber and Coates obtained the opposite result with carbon monoxide.

T. E.

The Behaviour of Nitrous Gases towards Water and Aqueous Alkalies. FRITZ FOERSTER and J. BLICH (*Zeitsch. angew. Chem.*, 1910, 23, 2017—2025. Compare Abstr., 1908, ii, 941, 1031).—The rate of oxidation of nitric oxide by air under different conditions has been determined by absorbing the product in sodium hydroxide and determining the ratio of nitrite to nitrate formed.

In the authors' apparatus, the gases issuing from the large oxidation chamber pass through two vessels containing water, after which the mixture contains nitric oxide as well as peroxide. The third vessel

contains sodium hydroxide. Lengthening the path between the water and alkali increases the completeness of the oxidation, but no improvement is brought about by interposing heated glass spirals. Experiments in which air and nitric oxide pass together into a heated vessel containing broken glass show that the reaction $2\text{NO} + \text{O}_2 \rightarrow 2\text{N}_2\text{O}$ proceeds less rapidly as the temperature rises. This result has also been observed by Bodenstein, and is best explained by the assumption that a molecular oxide is first formed: $\text{NO} + \text{O}_2 \rightarrow \text{NO}\cdot\text{O}_2$, $\text{NO}\cdot\text{O}_2 + \text{NO} \rightarrow 2\text{NO}_2$ (compare Raschig, *Abstr.*, 1907, ii, 455).

The experiments also show that alkalis absorb nitrogen trioxide more rapidly than nitrogen peroxide. It appears probable that in a partly oxidised mixture the equilibrium $\text{NO} + \text{NO}_2 \rightleftharpoons \text{N}_2\text{O}_3$ exists, although the quantity of trioxide is small, and that the water absorbs the gases in this form (compare Le Blanc, *Zeitsch. Elektrochem.*, 1905, 12, 544). When pure liquid nitrogen trioxide is added to sodium hydroxide solution at -22° , it is instantly absorbed, whilst liquid nitrogen peroxide only reacts slowly.

C. H. D.

The Reduction of Nitrosyl Chloride. HUMPHREY O. JONES and J. K. MATHEWS (*Proc. Camb. Phil. Soc.*, 1910, 15, 529—530).—When nitrosyl chloride and ethyl mercaptan react in ethereal solution at -80° , small quantities of hydroxylamine hydrochloride are formed. The action of other reducing agents on nitrosyl chloride has therefore been studied, but the formation of hydroxylamine hydrochloride has only been observed when nitrosyl chloride and hydrogen are passed over reduced platinum, cooled in a freezing mixture. Even in this case the hydroxylamine hydrochloride only forms 5% of the ammonium chloride produced. When the contact substance is nickel, the product is ammonium chloride.

With palladium, the products at the ordinary temperature are palladium chloride, nitric oxide, and nitrogen; at higher temperatures ammonium chloride is formed.

Hydrogen sulphide and nitrosyl chloride interact at a low temperature in ether or light petroleum, the principal reaction being

C. H. D.

Presence of a Small Quantity of Carbon Monoxide in the Atmosphere of Coal Mines. P. MAHLER and J. DENET (*Compt. rend.*, 1910, 151, 645—647. Compare this vol., ii, 607; Boudouard, *Abstr.*, 1909, ii, 234).—Carbon monoxide has been found to occur in the air of well-ventilated coal mines to the extent of about 0.002% by volume; the maximum amount found was 0.004%. Iodic anhydride was employed to estimate the carbon monoxide, and precautions were taken to avoid the influence of traces of dust or unsaturated hydrocarbons.

W. O. W.

Silicates with Linked Silicon Atoms. WILHELM MANCHOT (*Ber.*, 1910, 43, 2603—2604).—In his lecture before the German Chemical Society (this vol., ii, 780), W. Pukall represents the constitution of

“kaolin-acid” as $\text{OH}\cdot\text{Si}\cdot\text{O}\cdot\text{O}\cdot\text{Al}(\text{OH})_2$, there being a double linking

between the two atoms of silicon. A similar constitution is given to kaolin.

The author points out that such substances should evolve hydrogen when treated with hydrofluoric acid, or with hydrofluoric acid followed by alkali (compare Abstr., 1905, ii, 165; 1908, ii, 46), and that therefore the above formula is an impossible one. Moreover, the doubly linked atoms of silicon would indicate that a reduction of silicic acid had taken place in the preparation of the compound, whereas no reduction could take place according to the method of preparation described by Pukall. Such a linking would be broken by the action of alkali and not be stable, as postulated by Pukall.

T. S. P.

Preparation of Argon. GEORGES CLAUDE (*Compt. rend.*, 1910, 151, 752-753).—Details are given of a laboratory method for preparing argon at the rate of 2-3 litres per hour. The compressed oxygen of commerce, when obtained from liquid air, contains over 3% of argon, and is a convenient source of this element. The oxygen is absorbed by reduced copper, and the small amount of nitrogen by heated magnesium.

W. O. W.

Determination of the Velocity of Sound in Potassium Vapour and the Monatomicity of its Molecules. WILHELM WEIZ (*Ann. Physik.*, 1910, [iv], 33, 951-970).—Measurements of the velocity of sound in potassium vapour have been made by Quincke's resonance method at 850°. The vapour was contained in a steel tube surrounded by a wider porcelain tube, which was heated electrically. The one end of the steel tube was closed by a thin mica plate serving as a vibrating resonance diaphragm. In order to obtain satisfactory results with this at the high temperature, it was found necessary to protect the inner surface with a thin layer of silver. The other end of the tube was formed by a piston which could be moved up and down, and by this means the length of the column of vapour could be varied. The distances between successive positions in which resonant vibration was obtained were determined, and compared with the corresponding lengths for air. The measurements give 1.77 for the ratio of the specific heats. From this, the author concludes that the vapour of potassium consists of monatomic molecules.

H. M. D.

Equilibrium in the System: Potassium Iodide, Iodine, and aqueous Alcohol. CHARLES L. PARSONS and H. P. CORLISS (*J. Amer. Chem. Soc.*, 1910, 32, 1367-1378).—The solubility of iodine and potassium iodide in aqueous-alcoholic solutions containing varying amounts of potassium iodide and iodine respectively has been measured at 25°. In an alcohol-water mixture containing 60% of alcohol, two solubility curves are obtained, which intersect at a point corresponding with a solution containing 20.0% of potassium iodide and 72.5% of iodine. Similar results were obtained with a solvent containing 40% of alcohol, the point of intersection of the two curves corresponding in this case with 25% of potassium iodide and 76.8% of iodine. The limiting solutions

indicated are those which are simultaneously saturated with respect to iodine and potassium iodide. The solubility data afford no evidence of the formation of solid polyiodides, and the absence of these has been confirmed by analyses of the solid phases in contact with the saturated solutions.

The question of the existence of polyiodides in solution is discussed and experiments are described which show that the iodine and potassium iodide in an aqueous solution of these substances can be partly separated by diffusion. These results are interpreted as indicating that polyiodides are not formed to any appreciable extent. The increased solubility of iodine in an iodide solution as compared with pure water is attributed to the high solvent power of the dissolved solid.

H. M. D.

Sodium Tellurides. GIOVANNI PELLINI and E. QUERCIGH (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 350—356. Compare Tibbals, *Abstr.*, 1909, ii, 728).—With a view to throwing further light on the analogy between tellurium, sulphur, and selenium, the authors have investigated the sodium tellurides by thermal methods. The cooling curves of mixtures of the two elements were observed in an atmosphere of nitrogen, a quartz vessel being employed, and the temperatures measured by means of a platinum and platinum-rhodium couple. The results obtained are also exhibited in a curve, from which it follows that under the conditions of the experiment three compounds can exist, namely, Na_2Te , Na_3Te_2 , Na_3Te_3 . Only the first melts unchanged. It is whitish in colour, but rapidly darkens in the air, and is very deliquescent. The other two have a grey, metallic aspect. In these circumstances it was not possible to obtain the compound Na_2Te prepared by Tibbals (*loc. cit.*). The formulæ of these tellurides differ from those of the selenides (compare Mathewson, *Abstr.*, 1907, ii, 682) and sulphides, except in the case of the type Na_3Te .

R. V. S.

The Equilibrium Diagram of the Silver-Sodium Alloys. E. QUERCIGH (*Zeitsch. anorg. Chem.*, 1910, 68, 301—306).—Sodium does not react appreciably with silver below 700° . The alloys may be prepared in all proportions by fusion in a current of nitrogen, and separation into two liquid layers does not take place. The freezing-point curve falls rapidly at first, then slowly, and then, from 90 atomic % Na, very rapidly. The eutectic point lies not more than 0.1° below the freezing point of sodium. Solid solutions of sodium in silver are formed up to 13 atomic % Na.

C. H. D.

Photo-Halides. I. WILLEM REINDERS (*Chem. Weekblad*, 1910, 7, 961—973).—Crystalline photo-chlorides of silver have been prepared by crystallising silver chloride from dilute aqueous solutions of ammonia in presence of sunlight. The crystals were indigo-blue in colour, the depth of tint depending on the intensity of the light and the duration of the crystallisation. The darkest crystals contained about 1% of free silver. Exposure under blue glass during crystallisation

tion did not affect the colour of the resulting crystals, but with green or yellow glass the tint was much lighter, and with red glass colourless crystals were formed. During exposure to light for several hrs. the colour of the crystals changed to reddish-brown, and they became opaque. Longer exposure to light produced a grey colour with metallic lustre. These colour changes are caused by superficial reduction to metallic silver. The free silver present in the photo-chloride is in the colloidal state.

Crystallisation from a solution of colloidal silver was effected by addition of a small proportion of formaldehyde to a saturated solution of silver chloride in ammonia (4*N*), slow reduction to a colloidal solution of silver taking place. In transmitted light, the resulting crystals were light yellow to reddish-brown in colour, whilst in reflected light they were yellow, chocolate-brown, or green. They did not contain more than 1—2% of free silver. In diffused sunlight, they changed slowly in colour from yellow to indigo-blue, with production of intermediate shades of red, reddish-violet, and violet-blue.

A. J. W.

The So-called Emulsion of Silver Iodide. JOHN K. THURMER. *J. Pharm.*, 1910, 82, 507—508).—When silver nitrate reacts with potassium iodide dissolved in a solution of egg-albumin, the water part of the precipitated silver iodide is maintained in colloidal solution. Irish moss mucilage gives fairly good results as a substitute for egg-albumin.

Solutions of gelatin (0.1—0.5%) in water also give good suspensions. In this medium the precipitates at first fall to the bottom of the flask, but permanent, almost perfect suspension can then be obtained by agitation, and the suspension improves on keeping.

T. A. H.

The Tellurides of Silver. GIOVANNI PELLINI and E. QUERCIGHI. *R. Accad. Lincei*, 1910, [v], 19, ii, 415—421).—The mixtures of tellurium and silver are melted in a current of nitrogen. The cooling-point diagram indicates the formation of two compounds, Te and Ag_2Te , the first being marked by a break in the curve at 12° , and the second by a maximum at 959° . There are two eutectic pts., at 351° and 33.3 atomic % Ag, and at 872° and 86 atomic % Ag respectively. The compound AgTe undergoes a transformation at 12° , but a polymorphic change of Ag_2Te , which is identical with the mineral hessite, is not observed.

The alloys are crystalline and metallic in appearance, changing from grey to white as the silver increases. The brittleness diminishes from tellurium to silver.

C. H. D.

The Absorption of Bromine by Lime. W. A. R. WILKS (*Proc. Phil. Soc.*, 1910, 15, 526—528).—Solutions of bromine in carbon tetrachloride react with slaked lime with the formation of a reaction product. Using weak solutions of bromine, the concentration of bromine in the lime increases with the concentration of the solution, the ratio $C_1/C_2^{1/4}$ being sensibly constant, pointing to the

formation of an adsorption product. With more concentrated solution of bromine, the quantity taken up is independent of the concentration and the ratio $\text{Ca}(\text{OH})_2:\text{Br}=4.42:1$, indicating the formation of compound. With dry slaked lime, the ratio soon becomes constant: 14.9:1, the equilibrium concentration of bromine being thus much lower, a result similar to that observed with bleaching powder. The colour of the product increases until the constant concentration is reached.

C. H. D.

Anhydrous Sulphates G. CALCAGNI and G. MANCINI (*Atti Accad. Lincei*, 1910, [v], 19, ii, 422—427).—The double sulphates of calcium and the alkali metals have been studied by D'Ans (Abstr. 1909, ii, 401). The freezing-point curve of mixtures of calcium sulphate and sodium sulphate has now been determined. Pure calcium sulphate decomposes so readily at 1000° that its freezing point cannot be determined, but extrapolation of the curve gives 1375° . Sodium sulphate melts at 887° and undergoes a polymorphic change at 234° ; this transformation is not observed in mixtures containing more than 7% of calcium sulphate. The curve has a single maximum at 949° , corresponding with the compound $3\text{Na}_2\text{SO}_4.\text{CaSO}_4$, an analogue of vanthoffite, $3\text{Na}_2\text{SO}_4.\text{MgSO}_4$. The eutectic point is at 917° and 5% Na_2SO_4 , corresponding with the composition of the mineral glauberite. It is possible that other double salts may exist at lower temperature, especially glauberite and the pentacalcium sulphate.

Between 73% and 82.6% of sodium sulphate, two liquid layers are formed.

C. H. D.

[Calcium Silicides.] ADALBERT KOLN (*Zeitsch. anorg. Chem.*, 1910, 68, 297—300).—A reply to Hünigschmid (this vol., ii, 303) maintaining the accuracy of the author's formulae for the calcium silicides (this vol., ii, 35).

C. H. D.

The Temporary Hardness of Water. HERMANN NOLL (*Zeitsch. angew. Chem.*, 1910, 23, 2025—2029. Compare Abstr., 1908, ii, 453).—The solubility of calcium carbonate in water free from carbon dioxide is lessened by the presence of magnesium carbonate. Experiments are described to determine the influence of magnesium salts and of organic substances on the temporary hardness, but without definite result.

C. H. D.

Preparation of Crystalline Strontium. ANTOINE GUXTE and GALLIOT (*Compt. rend.*, 1910, 151, 813).—A mixture of anhydrous strontium oxide with the calculated amount of aluminium is heated for four hours at 1000° in a steel tube (10 cm. long, 3 cm. diam.), which is placed in an evacuated porcelain tube. On cooling, the inner tube is found to be coated with silver-white crystals of strontium containing 99.4% of the metal. The product has D 2.65 and the yield is 75% of the theoretical.

W. O. W.

Solubility of Strontium Nitrate and Strontium Hydroxide in the Presence of Each Other. CHARLES L. PARSONS and C. L. PERKINS (*J. Amer. Chem. Soc.*, 1910, 32, 1387—1389).—The solubility

data obtained at 25° can be represented by means of two curves intersecting at a point which gives the composition of the solution saturated with respect to both substances. This solution contains 1.76 parts of strontium oxide and 81.06 parts of strontium nitrate per 100 parts of water. The curves are quite similar to those obtained in the case of barium nitrate and barium hydroxide (compare following abstract), and show that no basic nitrates of strontium are capable of existence at 25°.

H. M. D.

Solubility of Barium Nitrate and Barium Hydroxide in the Presence of Each Other. CHARLES L. PARSONS and H. P. CONSON (*J. Amer. Chem. Soc.*, 1910, 32, 1383—1387).—These measurements were made to ascertain whether a basic barium salt analogous to the calcium salt, $\text{CaO} \cdot \text{Ca}(\text{NO}_3)_2 \cdot 3\frac{1}{2}\text{H}_2\text{O}$, is capable of being obtained.

The graphical representation of the solubility data for 25° gives two curves meeting at a point corresponding with a solution which contains 5.02 parts of barium oxide and 11.48 parts of barium nitrate in 100 parts of water. This solution is saturated with respect to both $\text{Ba}(\text{OH})_2 \cdot 8\frac{1}{2}\text{H}_2\text{O}$ and $\text{Ba}(\text{NO}_3)_2$. The saturated solutions of the two substances separately contain respectively 4.29 parts of barium oxide and 10.30 parts of barium nitrate per 100 parts of water. The solubility of each substance is increased in presence of the other. The data show that basic nitrates of barium are not formed at 25°.

H. M. D.

The Action of Solutions of Borax on Zinc Salts. FRIEDRICH BORCHERS (*Zeitsch. anorg. Chem.*, 1910, 68, 269—291).—The composition of the precipitate obtained from borax and zinc salts is very variable. The possible equilibria have now been studied in detail. The reaction may be expressed thus:

The borax is employed in most of the experiments as a saturated solution, but also occasionally in the solid form or as a supersaturated solution. For the analysis, a part of the filtrate is precipitated with sodium carbonate to remove zinc, neutralised with standard hydrochloric acid with methyl-orange as indicator, and after boiling to remove carbon dioxide, glycerol is added, and the solution is titrated with potassium hydroxide, using phenolphthalein as indicator.

Boric acid does not react with zinc oxide or hydroxide to form solid zinc borate, although some zinc goes into solution, but boric acid and zinc carbonate react readily.

The largest yield of zinc borate is obtained by adding a concentrated solution of a zinc salt to a slight excess of saturated borax solution. The maximum proportion of borax thus precipitated as zinc borate is 8.6% using solid zinc sulphate. Higher results are obtainable from supersaturated borax solution or solid borax. An excess of zinc salt diminishes the yield, complex zinc salts being formed. Indifferent salts have a similar effect, a large excess of magnesium chloride, for instance, preventing precipitation completely.

If the hydrolysis of the borax is checked by the addition of boric acid, the whole of the borax, and even a part of the added boric acid

may be precipitated by means of a zinc salt. Borax does not produce any precipitate with sodium zincoxide, but by addition of only small quantities of sodium hydroxide the precipitation is rendered more complete. If the zinc borate is removed by filtration, and an excess of sodium hydroxide, followed by zinc sulphate, is added to the filtrate, a further precipitate is obtained, and this process may be repeated until 94% of the borax has been converted into zinc salt. Sodium carbonate has less effect than sodium hydroxide, and the addition of sodium chloride or sulphate then modifies the reaction.

Manganous salts behave similarly to zinc salts.

C. H. D.

Hydrates of Cadmium Nitrate. ALEXIS M. VASILIEFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 562—567).—Cadmium nitrate, which crystallises from aqueous solution with $4\text{H}_2\text{O}$, can be obtained, like the corresponding silver salt, in the anhydrous state by the evaporation of the hydrate. Contrary to Funk's statement (*Abstr.*, 1899, ii, 209), no salt with $2\text{H}_2\text{O}$ or $6\text{H}_2\text{O}$ could be obtained. At low temperatures, however, a salt with $8\text{H}_2\text{O}$ was produced. The anhydrous salt melts at about 350° , and dissolves in water with development of much heat. The solubility curve of the anhydrous salt, $\text{Cd}(\text{NO}_3)_2$, in the hydrate, $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ (investigated in the solid condition in Flawitsky's apparatus: *Abstr.*, 1909, ii, 886), has a break beyond the m. p. of the hydrate, 59.5° , descending to 44.5° , which is the eutectic point of the mixture, and corresponds with the composition $\text{Cd}(\text{NO}_3)_2 \cdot 2.65\text{H}_2\text{O}$; the curve then rises continuously to the m. p. of the anhydrous salt, about 350° .

Z. K.

The Binary and Ternary Alloys of Cadmium, Bismuth, and Lead. WILLIAM E. BARLOW (*J. Amer. Chem. Soc.*, 1910, 32, 1390—1412).—From observations of the rate of cooling of the molten alloys, the author has determined the freezing-point curves for the pairs of metals: lead-cadmium and lead-bismuth. By combination of these results with the data obtained in experiments on alloys containing the three metals, the solidification diagram for the ternary system has been deduced.

Lead and cadmium give rise to two curves intersecting in a eutectic point, which corresponds with 82.6% of lead and a temperature of 247.3° . On the cadmium side, the form of the curve points to a slight solubility of lead in solid cadmium, and on the lead side, cadmium appears to dissolve in the solid lead to the extent of about 3%.

Lead and bismuth yield a similar diagram, the eutectic temperature being 124.3 — 124.8° , and the composition corresponding with 56.5% of bismuth. On the bismuth side, the data indicate that bismuth dissolves in solid lead to the extent of about 11%.

From the very numerous observations which have been made with alloys containing the three metals, a triangular diagram has been constructed. The ternary freezing point is sharply defined at 91.4 — 91.5° , and the composition of the ternary eutectic is given as 40.2% lead, 51.65% bismuth, and 8.15% cadmium.

H. M. D.

Equilibria in the Precipitation of Lead Hydroxide. WALTER HERZ (*Zeitsch. anorg. Chem.*, 1910, 68, 421—424).—When lead oxide is shaken with an alkali halide and water, the whole mass becomes pasty, and it is therefore necessary to approach the equilibrium from the other side. The formation of basic salts may be left out of consideration. The constant $[\text{PbCl}_2][\text{KOH}]^2/[\text{KCl}]^2$ is found to be 0.00073, and for the corresponding reactions with ammonia and methylamine, 0.00082 and 0.00066 respectively. The solubility of lead hydroxide is calculated to be 0.93×10^{-4} . C. H. D.

Basic Lead Carbonates. LEOPOLD FALK (*Chem. Zeit.*, 1910, 34, 937—938).—When lead carbonate is shaken with a solution of basic lead acetate, three parts of carbonate withdraw two parts of oxide from solution, as shown by titration, but the washed precipitate always contains too much carbonate for the formula. If boiled with the basic lead acetate solution the ordinary basic carbonate, $2\text{PbCO}_3 \cdot \text{Pb}(\text{OH})_2$, is obtained.

Crystalline and amorphous lead carbonates differ in their chemical behaviour. Thus, whilst the crystalline compound reacts readily with lead oxide in presence of lead acetate, the amorphous modification only reacts very slowly. The formulae $\text{CO} \begin{array}{c} \diagup \text{O} \diagdown \\ \diagdown \text{O} \diagup \end{array} \text{Pb}$ and

are proposed for the two modifications, and a similar polymerisation is assumed in the case of white lead. Structural formulae for the basic carbonates are proposed.

Hydrogen sulphide only reacts very slowly with crystalline white lead, but rapidly with the amorphous variety. C. H. D.

Solubility of Lead Sulphate and Lead Chromate, and of Mixtures and Oil Colours Containing the two Salts in Dilute Hydrochloric Acid. The Equilibrium between Chromate and Dichromate in Solution. KARL BRICK and PH. STEGMÜLLER (*Arch. K. Gesundh.-Amt*, 1910, 34, 446—483).—Measurements have been made of the solubility of lead sulphate and lead chromate in 0.1N- to 0.6N-hydrochloric acid at 18°, 25°, and 37°. The data for lead sulphate show that, at constant temperature, the solubility is approximately proportional to the concentration of the hydrogen ions. In the case of lead chromate, the solubility in the more dilute solutions is nearly proportional to the hydrogen ion concentration, but in the more concentrated solutions it is more nearly proportional to the square of the concentration of these ions. The increase in solubility with rise of temperature is linear for both salts, the increase per 1° being 2.1% for the sulphate, and 3.5—4% for the chromate.

The equilibria in the solutions have been examined theoretically, and it is shown that the observed differences in the dependence of the solubility of the two salts on the concentration of the acid is due to the formation of dichromate ions in accordance with the equation:

In acid solutions less concentrated than 0.3N, the effect of this change

is not very marked, but in the stronger solutions it results in a considerable increase in the amount of lead chromate dissolved per mol. of acid present. In connexion with the analysis of the equilibrium in solution, measurements were made of the solubility of lead sulphate in 0.1 to 0.4*N*-solutions of sodium chloride and nitric acid, and of lead chromate in 0.1 to 0.6*N*-nitric acid. From these data the following equilibrium constants are calculated: $[H^+][CrO_4^{=2}]/[HCrO_4^{\cdot-}] = 3.7 \times 10^{-7}$, $[H^+]^2[CrO_4^{=2}]/[Cr_2O_7^{\cdot-}] = 3.4 \times 10^{-13}$, $[H^+][Cr_2O_7^{\cdot-}]/[HCr_2O_7^{\cdot-}] = 1.0 \times 10^{-3}$, $[HCrO_4^{\cdot-}]^2/[Cr_2O_7^{\cdot-}] = 2.5$.

Data are also recorded showing the quantities of lead dissolved by 0.1 to 0.4*N*-hydrochloric acid solutions in presence of both sulphate and chromate, and these are supplemented by observations showing the rate at which oil colours containing these two substances are attacked by dilute hydrochloric acid solutions.

H. M. D.

The Ternary System Copper-Antimony-Bismuth. N. COLA PARRAVANO and E. VIVIANI (*Atti R. Accad. Sci. Fis. Mat. Napoli*, 19, ii, 343-449. Compare this vol., ii, 956).—In this system, the results obtained in the examination of the ternary system $Cu_3Sb-Cu-Bi$, the second of the two systems into which the system $Cu-Sb-Bi$ resolves itself. The diagram constructed from them differs from that which was deduced on general grounds, because both copper and bismuth and Cu_3Sb and bismuth form eutectics which practically coincide with bismuth. Photomicrographs of some typical alloys are given. In conclusion, the space of miscibility in the liquid state is discussed, the limits of the space in the two systems being obtained by analysis of the two layers in equilibrium at about 370°, which is very near the initial temperature of solidification of alloys in that region. Uniting the two systems $Cu_3Sb-Cu-Bi$ and $Cu_3Sb-Sb-Bi$ in one diagram, it then becomes possible to exhibit on it the closed curve representing the boundary of the space of miscibility. All alloys within the curve separate into two layers, whilst those outside it are miscible in all proportions.

R. V. S.

Action of Chlorine in Carbon Tetrachloride Solution and of Carbon Tetrachloride on Metallic Oxides. ARTHUR MICHAEL and ARTHUR MURPHY, jun. (*Amer. Chem. J.*, 1910, 44, 365-384).—This investigation was undertaken originally with the object of ascertaining the relation between the position of metals in the periodic system and the behaviour of their unsaturated oxides towards chlorine.

The following experiments were made with a 10% solution of dry chlorine in carbon tetrachloride. With ferrous oxide, a violent action occurs, even when the chlorine solution is cooled to -18°, with formation of ferric oxide and chloride: $6FeO + 3Cl_2 = 2Fe_2O_3 + 2FeCl_3$. Manganous oxide reacts less violently; nickelous oxide reacts readily at the ordinary temperature, but the reaction is not complete for a considerable time; in the case of cobaltous oxide, the mixture must be heated at 100° in a sealed tube in order to complete the reaction. These reactions may be represented by the general equation: $3MO + Cl_2 = M_2O_3 + 2MCl_2$. Stannous oxide reacts violently with the solution.

with formation of stannic chloride and a light brown oxide, probably identical with the oxide, $\text{SnO} \cdot 20\text{SnO}_2$, obtained by Schiff (*Annalen*, 1861, 120, 52) by treating stannic acid with a solution of stannous chloride. Cuprous oxide requires to be heated at 250° with the solution in order to effect a reaction; *cupric oxychloride*, Cu_2OCl_2 , is thus obtained as a dark brown, amorphous powder. Antimony trioxide reacts with the chlorine solution at 100° in a sealed tube in accordance with the equation: $\text{Sb}_2\text{O}_3 + 3\text{CCl}_4 + 2\text{Cl}_2 = 2\text{SbCl}_3 + 3\text{COCl}_2$. In the case of silver oxide, the following reaction takes place at the ordinary temperature: $\text{Ag}_2\text{O} + \text{Cl}_2 + \text{CCl}_4 = 2\text{AgCl} + \text{COCl}_2 + \text{Cl}_2$. The chlorine evidently behaves as a catalyst, since when the oxide is heated with carbon tetrachloride in the absence of free chlorine, carbonyl chloride is not produced until a temperature of about 250° is reached. Lead oxide reacts with the solution at 100° in accordance with the equation: $2\text{PbO} + \text{Cl}_2 = \text{PbO}_2 + \text{PbCl}_2$. Mercuric oxide, although reacting readily with chlorine gas, even at 0° , is not affected by a $\frac{1}{2}^\circ\text{C}$ in the presence of carbon tetrachloride unless the mixture is heated in a sealed tube; the products thus obtained consist of mercuric chloride and some basic chlorides.

When molybdenum dioxide is heated with carbon tetrachloride in a sealed tube at 250° , it is converted into the tetrachloride. Molybdenum trioxide reacts with carbon tetrachloride at 280° with formation of the pentachloride. When the trioxide is heated with a solution of chlorine in carbon tetrachloride at 200° , the product consists of a yellowish-green oxychloride mixed with unchanged trioxide; at 225° , a mixture of yellow and green compounds is obtained, probably consisting of the dioxy-dichloride and the oxytetrachloride; at 240° , the pentachloride is produced. The pentachloride is also obtained when the oxide, Mo_3O_8 , is heated with carbon tetrachloride at 240° . When tungsten trioxide is heated with the chlorine solution, the oxychloride, WOCl_4 , is formed at 240° , and the hexachloride at 280° ; in the absence of free chlorine, reaction does not occur at 240° , but at 280° the hexachloride is produced. Uranium dioxide, if heated with carbon tetrachloride at 250° , yields the tetrachloride, whilst the oxides UO_2 and U_3O_8 , when heated at the same temperature, give the pentachloride. E. G.

Diffusion Phenomena of the Alums. CHARLES L. PARSONS and W. W. EVANS (*J. Amer. Chem. Soc.*, 1910, 32, 1378—1383).—Solutions of alum, when allowed to undergo diffusion into distilled water through a parchment or agar-agar diaphragm, are more or less completely separated into the component simple sulphates. Similar results were obtained at 25° and at 0° . The separation is more complete in the case of the chrome alums than in that of the aluminium alums. The authors draw the conclusion that the dissolved alums are more or less completely resolved into the simple sulphates. H. M. D.

Composition of Some Greek Vases. WILLIAM FOSTER (*J. Amer. Chem. Soc.*, 1910, 32, 1259—1264).—A study has been made of the nature and composition of the black glaze of vases of the black-figured and red-figured Attic styles and the red glaze of the Mycenaean style.

The black colour of the glaze of fragments of some Greek vases was found not to be due to manganese, as has been suggested, but to the presence of ferrous iron, probably existing as silicate.

The red colour of the glaze of a fragment of a Mycenaean vase was found to be due to the presence of ferric iron.

A fragment of a vase of the Mycenaean style has been analysed, and the results are compared with those recorded for Attic and Campanian pottery. The Mycenaean pottery contains considerably less silica and much more lime than the other varieties, and yields a large quantity of carbon dioxide. The percentage of aluminium is about the same in each case, but the Campanian ware contains about twice as much ferric iron as the Mycenaean and Attic. The amount of magnesium is about the same in the Mycenaean and Attic varieties, but is much less in the Campanian.

E. G.

The Structure of Cast Iron in the Graphitic Condition. OTTO KRÖHNKE (*Metallurgie*, 1910, 7, 674—679).—When cast iron is transformed into the "graphitic" condition by fusion, the ferrite is removed from the pearlite, whilst cementite and iron phosphide remain unaltered. The graphite retains its position in the mass, but is partly converted into a white or grey substance, graphitite, the composition of which is unknown. White cast iron does not undergo such a change, the constituents being resistant to corrosion. Wrought iron, although containing pearlite in small quantities, does not corrode in this way, the presence of graphite being necessary to produce the requisite electrolytic couples.

C. H. D.

Case-Hardening. SYDNEY A. GRAYSON (*J. Iron Steel Inst.*, 1910, 81, 287—302).—The case-hardening of steel by means of carbonaceous mixtures takes place best at 950—1000°. At 900—950°, diffusion being very slow, a highly supersaturated external layer is produced. Sulphur diffuses in a similar manner to carbon at the same temperature.

C. H. D.

The Crystallography of the Iron-Carbon System. ADOLPH KROLL (*J. Iron Steel Inst.*, 1910, 81, 304—385).—When steel is heated and cooled in an inert gas, relief patterns are obtained indicating the volume changes which have taken place at the critical points. The microscopical examination of etched sections shows that ordinary cementite is hexagonal, but that the carbide entering into solution in γ -iron is regular. A modified equilibrium diagram is proposed, in which a gap exists between two series of solid solutions, one of carbide in γ -iron and one of γ -iron in cementite, the latter solution being identical with troostite. This system is formed in tempering. A theory of the constitution of iron-carbon alloys, based on the crystallographic development, is proposed for the metastable systems, the only stable chemical equilibrium being that of ferrite and graphite.

C. H. D.

The Influence of Sulphur on the System Iron-Carbon. THEODOR LIESCHING (*Metallurgie*, 1910, 7, 565—571).—The distribu-

tion of iron sulphide in alloys of iron and carbon has been studied microscopically. The ferrous sulphide appears in low-carbon alloys in the form of thin films surrounding the crystals of ferrite. When the sulphur exceeds 2% in an alloy high in carbon, two liquid layers are formed, of which the lighter sulphide layer does not contain carbon.

C. H. D.

The Influence of Silicon on the Maximum Solubility of Iron Carbide in γ -Iron. CH. SCHOLS (*Metallurgie*, 1910, 7, 641—646).—The solubility of iron carbide in γ -iron is known to be diminished by the addition of silicon. Thermal and microscopical investigations of alloys prepared from iron and ferro-silicon show that the maximum solubility, which is at 2.2% C in the absence of silicon, is lowered to 1.9% by 1.34% Si, to 1.5% by 1.8% Si, and to 1.2% by 5.6% Si. The eutectic point remains constant at 1120°. The pearlite transformation point is slowly raised by the addition of silicon, but becomes imperceptible above 1.2% C if the alloy contains 5.6% Si, or above 1.5% C in the presence of 4.5% Si.

C. H. D.

Iron, Manganese, and Carbon. JOHN O. ARNOLD and ARTHUR A. READ (*J. Iron Steel Inst.*, 1910, 81, 169—181).—The carbides isolated from alloys of iron, manganese, and carbon by electrolysis show an increase in the ratio of manganese to iron as the proportion of manganese in the alloy is increased, becoming constant in steels containing from 4.98 to 13.38% Mn, afterwards increasing still further. The results do not decide whether double carbides or a mixture of the two carbides are present. Tested by the colour test, carbides of this kind indicate a lower percentage of carbon than pure iron carbide. Up to 10% Mn, the colour is only that due to the iron carbide present, showing that manganese carbide does not give a coloration with nitric acid, D 1.20. Alloys containing 11 or 14% Mn give a higher coloration with nitric acid.

C. H. D.

Some Physical Properties of 2% Chromium Steels. ANDREW McWILLIAM and ERNEST J. BARNES (*J. Iron Steel Inst.*, 1910, 81, 246—267).—The thermal analysis of steels containing 2% of chromium and varying quantities of carbon shows that the critical point A_{c2} is depressed below A_{c1} when the carbon is between 0.2 and 0.5%. The three critical points become identical in steels containing 0.65 or 0.85% C. The saturation point lies between the last two values. The microscopic structure does not indicate the form in which the chromium is present in the steel.

C. H. D.

The A_{c2} Point in Chromium Steel. HAROLD MOORE (*J. Iron Steel Inst.*, 1910, 81, 268—275).—The determination of the critical points of steels containing more than 3% of chromium shows that the position of A_{c1} is progressively raised by the addition of chromium, and that a new critical point appears below A_{c1} . The fact that the new point coincides with the temperature at which the magnetic properties of the steel disappear on heating, proves it to be identical with A_{c2} . An electromagnetic method is employed to determine this point (compare preceding abstract).

C. H. D.

Reduction of Ferric Oxide by Solid Carbon. GEORGES CHARPY and S. BONNEROT (*Compt. rend.*, 1910, 151, 644-645. Compare this vol., ii, 215).—The authors have studied the speed of reaction between ferric oxide and carbon at low pressures (0.001–8 mm.) to avoid as far as possible the catalytic action of gases. The mode of procedure was similar to that employed when examining the cementation of iron under similar conditions. The conclusion drawn is that carbon is incapable of reducing ferric oxide below 950°, a temperature considerably higher than has hitherto been supposed necessary. •W. O. W.

The System Nickel-Sulphur. KARL BORNEMANN (*Metallurgie*, 1910, 7, 667–674. Compare Abstr., 1908, ii, 292).—The experiments with mixtures high in nickel have been repeated, using magnesia vessels and quartz protecting tubes for the thermo couples. Care being taken to avoid undercooling, the break in the freezing-point curve formerly observed at 1 atomic % S disappears, and only a single series of solid solutions rich in nickel is observed, extending from 0 to 0.5 atomic % S. The complicated transformations in the solid state are confirmed. C. H. D.

Preparation of Anhydrous Chromic Chloride by Bourion's Method. JOSÉ RODRÍGUEZ MOCHELO (*Anal. Fis. Quím.*, 1910, 8, 196–199).—Although chlorine in presence of carbon attacks chromium sesquioxide prepared by gently igniting chromium hydroxide, it is without action on the crystalline sesquioxide or the sesquioxide obtained by ignition at a high temperature. But by Bourion's method (Abstr., 1909, ii, 220) these indifferent substances are rapidly converted into beautifully crystalline scales of chromic chloride; it is only necessary to pass the vapour of sulphur chloride (b. p. 137–139°) over the oxide heated gradually to a red heat, and, after the action is complete, to cool in a current of dry hydrogen chloride. W. A. D.

Uranium Salts. I. and II. ALEXIS M. VASILIEFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 570–581).—Uranium nitrate gives three hydrates, $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, $\text{UO}_2(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, and the dihydrate, $\text{UO}_2(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$, but the nitrate, $\text{UO}_2(\text{NO}_3)_2 \cdot 1\frac{1}{2}\text{H}_2\text{O}$, does not exist. The hydrate, $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, melts at 60–72°, and when further heated just above this temperature, is transformed into the trihydrate, but if heated at a higher temperature a basic salt is formed, which, however, dissolves in water to a yellow solution.

The trihydrate, m. p. 121.5°, forms crystals belonging to the monoclinic system, and can also be obtained by crystallising a strongly acid solution of the sesquihydrate in nitric acid (D 1.4). The dihydrate, m. p. 179.3°, forms small, thick, square plates, probably of the rhombic system, very bright and with a green fluorescence. It is formed when the sesquihydrate is kept for some time in a desiccator at the ordinary temperature, or when the latter hydrate is treated thus at 100°, and the product, which now contains slightly less than $2\text{H}_2\text{O}$, is dissolved in nitric acid, D 1.503, and then allowed to crystallise. When the substance containing less than $2\text{H}_2\text{O}$ is treated

with water, the sesquihydrate separates. Tables and a curve are given for the solubility of the sesquihydrate in water, and the theoretical significance of these are discussed. Contrary to Oechsner de Couinck's statement (Abstr., 1901, ii, 101), the constitution of the solution at 13.5° is about $\text{UO}_2(\text{NO}_3)_2 + 19\text{H}_2\text{O}$. The constitution of the cryohydrate is $\text{UO}_2(\text{NO}_3)_2 \cdot 28.93\text{H}_2\text{O}$ at -18.1° .

Uranium nitrate is one of those salts for which the number representing the degree of dissociation increases with increasing concentration of the solution.

Z. K.

The Solution and Precipitation of Titanic Acid. KARL BORNEMANN and H. SCHIRMISTER (*Metallurgie*, 1910, 7, 646—649).—Contrary to the usual statement in text-books, titanitic acid which has been heated to 1000° is practically insoluble in sulphuric or hydrofluoric acid. If the temperature of ignition does not exceed 700° , solution in concentrated sulphuric acid is complete in fifteen minutes. Hydrofluoric acid has a rather greater solvent power.

Fusion with potassium hydrogen sulphate readily brings about complete solution. It is not necessary to dissolve the product in cold water, for if dilute sulphuric acid (1:2) is used, solution takes place completely even if the liquid is boiled. After fusion with alkali carbonate and solution in hydrochloric acid, the residue is difficult to wash, and readily passes through the filter. This is avoided by the use of sulphuric acid (1:2) instead of hydrochloric acid.

Orthotitanic acid may be precipitated from hot strongly acid solutions by the addition of ammonia without destroying its solubility in dilute acids. When metatitanic acid is dissolved in concentrated sulphuric acid, boiling for more than a few minutes must be avoided, or an insoluble precipitate is formed. No difference in this respect is observed between ortho- and meta-titanic acids.

C. H. D.

Zirconia and Erbium from Titanium Minerals. KARL A. HOFMANN (*Ber.*, 1910, 43, 2631—2636).—Hauy and Wirth have found that the zirconia contained in a number of zirconium minerals is not accompanied by a strange earth (this vol., ii, 713); the author finds that the principal mineral investigated by him, which differs from typical euxenite in that it has a very high titanium content, contains zirconia, which gives some strange lines in the arc-spectrum, and also has a higher equivalent weight than zirconia prepared from zirconium silicate.

The mineral used was euxenite from Brevig, and had the composition:

| CH_3O_2 | TiO_2 | Rare earths. | SiO_2 | PbO | ZrO_2 | Fe_2O_3 | UO_2 | CaO | Loss on heating |
|-------------------------|----------------|--------------|----------------|--------------|----------------|-------------------------|---------------|--------------|-----------------|
| 4.65 | 45.74 | 38.17 | 0.53 | 0.33 | 2.83 | 2.06 | 2.73 | 1.60 | 2.80% |

The rare earths comprised didymium, erbium, and holmium. The zirconia was identified by the preparation of the double fluoride with potassium, and from the mother liquors obtained in the recrystallisation of this salt zirconia was prepared, the arc-spectrum of which showed unknown lines (4519.6, 4322.65, 3682.43, 3662.29, 3253.83,

3194-30, and 3031-32), together with the known lines due to zirconium and titanium. These lines still persisted after the titanium had been removed.

The remainder of the paper deals with neo-erbium compounds. The erbium compounds contained in the rare earths mentioned above are purified from holmium and dysprosium by fractional crystallisation of the ammonium double oxalate (compare Abstr., 1908, ii. 189). Fractional crystallisation of the acetylacetonate compound from alcohol may also be used. Thulium and ytterbium may be readily separated from almost pure erbium sulphate by heating to 845° for ten hours; on treating the residue with water, the less basic portions remain undissolved. The solution is evaporated to dryness, the residue heated to 950° for thirty minutes, and then treated with water, when erbium oxide remains undissolved.

By using the above methods, an erbium material was obtained, which gave a constant spectrum and a constant equivalent weight. After freeing it from impurities derived from the vessel used, a bright rose-red oxalate was obtained, $\text{Er}_2(\text{C}_2\text{O}_4)_3 \cdot 10\text{H}_2\text{O}$. Former analyses have given $9\text{H}_2\text{O}$. On drying in a vacuum over phosphoric oxide, the trihydrate is formed. The oxide results on heating the oxalate to 575° ; it is obtained pure at 845° , and then forms a rose-coloured powder, which does not glow in cathode rays, but gives a green, discontinuous light in the bunsen flame. The reflexion spectrum is not altered by dilution with other oxides when no compound is formed.

Atomic-weight determinations were made by transforming the sulphate into the oxide by heating at 1055° , and gave the mean value 167.68 (three determinations, $O = 16$, $S = 32.07$). At 815° a basic sulphate, $\text{Er}_2\text{O}_3 \cdot \text{SO}_3$, is obtained. T. S. P.

Colloidal Zirconium Silicide. EDGAR WEDEKIND (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 249—251).—Zirconium silicide, obtained by the action of excess of silicon on potassium zirconium fluoride in the electric furnace, has been converted into a colloidal form by Kuzel's method. The finely divided substance was treated successively with dilute acid and alkaline solutions at a temperature of 50 – 60° , the treatment in each case being continued for about twenty-four hours. After a considerable number of such operations, a dark brown colloidal solution of the silicide is obtained. Under the microscope, the solution, which has been kept for some time, appears to be homogeneous, but the want of homogeneity is clearly seen in the ultra-microscope. The colloidal particles move towards the positive pole, and are therefore negatively charged. On the other hand, colloidal zirconium is positively charged, and coagulation takes place when solutions of the metal and of the silicide are mixed. Colloidal zirconium silicide is coagulated by various electrolytes, but in comparison with the colloidal metal, it is not at all readily acted on by solutions of alkali hydroxides. Coagulation of the silicide is also brought about by freezing the solution, and in this respect also it differs from the colloidal solution of zirconium. H. M. D.

Basic Thorium Sulphate. OTTO HAUSER (*Ber.*, 1910, 43, 2776—2778).—The author claims priority to Barre (this vol., ii, 718) in showing that Demarcay's salt (*Compt. rend.*, 1860, 93, 728), $3\text{Th}(\text{SO}_4)_2 \cdot \text{ThO}(\text{SO}_4) \cdot 4\text{H}_2\text{O}$, is really a mixture of $\text{Th}(\text{SO}_4)_3 \cdot 2\text{H}_2\text{O}$ and $\text{ThO}(\text{SO}_4) \cdot 2\text{H}_2\text{O}$ (compare *Abstr.*, 1909, ii, 54). He also confirms Barre's result that at 100° the stable basic sulphate has the composition $\text{ThO}(\text{SO}_4) \cdot 2\text{H}_2\text{O}$. At 125 – 180° the stable basic sulphate is $\text{ThO}(\text{SO}_4) \cdot \text{H}_2\text{O}$. The author's and Barre's results show that in moderately dilute solutions of thorium sulphate the basic sulphate, $\text{ThO}(\text{SO}_4)$, is produced, which, according to the temperature, crystallises with one or two molecules of water. In very dilute solutions the sulphate may be completely hydrolysed to the hydroxide. T. S. P.

Preparation of Vanadium. WILHELM PRANDL and BENNO BLEYER (*Ber.*, 1910, 43, 2602—2603. Compare *Abstr.*, 1909, ii, 1022).—Vanadium may readily be obtained by the thermite reaction, using the following mixture: 100 parts of fused and powdered vanadium pentoxide, 49.5 parts of aluminium powder, 20 parts of calcium fluoride. The action is carried out in a magnesia crucible, or, better still, in a box made of fluor spar. In the latter case it is not necessary to add the calcium fluoride to the reaction mixture.

The vanadium regulus obtained is 70–80% of the theoretical quantity, and is 95% pure. The impurity is chiefly oxygen; possibly a lower oxide of vanadium remains dissolved in the excess of vanadium and escapes the reducing action of the aluminium. T. S. P.

Red Platinum as Analogue of Purple of Cassius. LOTHAR WOHLER and A. SPENGLER (*Zeitsch. Chem. Ind. Kolloide*, 1910, 7, 243–249).—Experiments have been made to determine the cause of the red colour which appears when solutions of platinum salts are acted on by stannous chloride. These show that the red substance consists of colloidal metallic platinum in a very fine state of subdivision, and that the formation of this in place of the more usual brown colloidal metal is due to the action of stannic chloride and its products of hydrolysis as protective colloids. The red colloid is also formed when the reduction of platinum salts is effected by means of a solution of phosphorus in ether, if gelatin is added as a protective colloid. The identity of the two red substances has been established by spectroscopic observations.

If the colloidal solution obtained by reduction with stannous chloride is shaken up with ethyl ether or ethyl acetate, the organic solvents take up the red colour, and this is found to be connected with the solubility of stannic chloride in these media, in which it plays the part of protective colloid.

When the aqueous solution is diluted with a large volume of water, or when the ethyl acetate solution is poured into water, a chocolate-brown precipitate is obtained. According to Schnoeder (*Ann. Phys. Chem.*, 1869, [ii], 136, 105), this substance has the composition $\text{Pt}_2\text{Sn}_3\text{O}_{10}$. It is now found, however, that no definite compound is formed, but that the composition of the precipitate varies very considerably with the conditions under which it is produced. Analogous

to purple of Cassius, it appears to be a mixture of colloidal platinum and colloidal stannic acid, and this view is supported by the similarity in the properties of the two substances.

The blood-red colour which appears on reduction of silver nitrate by stannous nitrate in dilute nitric acid solution is similarly due to colloidal silver, and not to the formation of what have been described as silver stannates. On account of the instability of the red colloidal silver, the red solution quickly turns brown, and deposits a reddish-brown precipitate. The red modification of silver cannot be obtained by reduction by means of an ethereal solution of phosphorus.

H. M. D.

Mineralogical Chemistry.

Probable Identity of Podolite with Dahllite. WALDENAR T. SCHALLER (*Amer. J. Sci.*, 1910, [iv], 30, 309—310).—A comparison of the characters and analyses of dahllite (Brügger and Backström, Abstr., 1890, 714) and of podolite (W. Tschirwinsky, Abstr., 1907, ii, 481) [= carbapatite of P. N. Tschirwinsky, 1906] suggests the identity of these minerals. The composition of dahllite was expressed as $2\text{Ca}_2\text{P}_2\text{O}_7 \cdot \text{CaCO}_3 \cdot 2\text{H}_2\text{O}$ ($= \text{H}_{10}\text{Ca}_{20}\text{P}_{40}\text{C}_{10}\text{O}_{195}$), and of podolite as $3\text{Ca}_2\text{P}_2\text{O}_7 \cdot \text{CaCO}_3$ ($= \text{Ca}_{10}\text{P}_{12}\text{C}_3\text{O}_{180}$).

L. J. S.

Action of Carbon Tetrachloride Vapours on Minerals and Application to Quantitative Analysis. PAUL JANNASCH (*Ber.*, 1910, 43, 3135—3136).—A claim for priority over Camboulives (this vol., ii, 202; compare Abstr., 1909, ii, 728, 767). The following analyses of a fluorapatite from Renfrew County (Ontario) are given:

| Deduct from | | | | | | | | | |
|------------------------|--------------|--------------|-------------------------|----------------------|-----------------------|----------------------|------|---------|-------|
| P_2O_5 | CaO | MgO | Fe_2O_3 | K_2O | Na_2O | H_2O | F | O for F | Total |
| 39.68 | 54.67 | 1.31 | 0.19 | 0.50 | 0.62 | 0.12 | 3.75 | -1.57 | 99.90 |
| 39.74 | 54.74 | 1.22 | 0.18 | 0.47 | 0.90 | 0.10 | 3.68 | -1.54 | 99.75 |

T. S. P.

Identity of Stelznerite with Antlerite. WALDENAR T. SCHALLER (*Amer. J. Sci.*, 1910, [iv], 30, 311—312).—For the orthorhombic stelznerite from Chili, described by Arzruni and Thaddeeff (Abstr., 1893, ii, 563), the formula was given as $\text{CuSO}_4 \cdot 2\text{Cu}(\text{OH})_2$, whilst for the massive antlerite from Arizona, described by Hillebrand in 1889, the formula $3\text{CuSO}_4 \cdot 7\text{Cu}(\text{OH})_2$ was deduced. A microscopical examination of the latter shows that its optical characters, so far as these can be determined, do not differ from those of stelznerite, and it is pointed out that the analyses of antlerite approximate to the simpler formula. The name antlerite having priority, it is suggested that this should stand for the species [but how far this rule should apply in the case of incompletely described or incorrectly determined minerals is doubtful].

L. J. S.

New Kind of Vanadate in the Cupriferous Deposit of Bena d'le Padru, near Ozieri (Sassari). DOMENICO LOVISATO (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 326—333).—Analysis of the new mineral by Silvio Manis gave:

| V ₂ O ₅ | P ₂ O ₅ | PbO. | ZnO. | CuO. | Fe ₂ O ₃ | MnO. | H ₂ O. | Total. |
|-------------------------------|-------------------------------|-------|------|-------|--------------------------------|------|-------------------|--------|
| 19.87 | 0.18 | 58.76 | 2.45 | 13.13 | 6.54 | 0.05 | 3.45 | 99.43 |

Its hardness is inferior to that of calcite, and it has D₁₀₀ 5.716.

R. V. S.

Further Occurrences of Tantalum and Columbium in Western Australia. EDWARD S. SIMPSON (*Austral. Assoc. Report*, 1909, 310—315).—The following analyses are given: (I) Fergusonite from Cooglegong, D 5.82—6.65; (II) Euxenite from Cooglegong, D 5.37; (III) Microlite from Wodgina, D 5.422; (IV) Ixiolite (?) from Wodgina, D 7.36; (V) Cassiterite from Greenbushes.

| Ta ₂ O ₅ | Cb ₂ O ₅ | TiO ₂ | SnO ₂ | ThO ₂ | Y ₂ O ₃ | Er ₂ O ₃ | Ce ₂ O ₃ | $\frac{La_2O_3}{Hf_2O_3}$ | CaO. |

| I. 55.51 | 2.15 | 2.20 | — | 1.02 | 23.00 | 8.38 | 0.94 | — | 2.18 |
| II. 23.10 | 4.35 | 30.43 | — | 1.76 | 15.76 | 9.27 | 1.82 | 1.73 | 1.02 |
| III. 73.54 | 3.62 | — | 0.90 | — | — | — | — | — | 13.40 |
| IV. 70.49 | 7.63 | — | 3.92 | — | — | — | — | — | 0.42 |
| V. 1.76 | — | — | 97.63 | — | — | — | — | — | — |

| FeO. | MnO. | MgO. | UO ₃ | Al ₂ O ₃ | K ₂ O. | Na ₂ O. | Ignition. | Total. |
|-----------|-------|------|-----------------|--------------------------------|-------------------|--------------------|-----------|--------|
| I. trace | 0.87 | — | 1.18 | — | — | — | 3.36 | 100.79 |
| II. trace | 0.34 | 0.35 | 6.69 | 0.76 | — | — | 2.82 | 100.20 |
| III. 3.64 | 0.60 | 0.42 | — | — | 0.20 | 1.66 | 1.23 | 99.32 |
| IV. 1.34 | 10.87 | 0.37 | — | — | — | — | 0.18 | 100.22 |
| V. 0.61 | — | — | — | — | — | — | — | 100.00 |

The analytical results for fergusonite agree with the usually accepted formula, R₂O₃Ta₂O₅; those for ixiolite, with the formula MnO₃Ta₂O₅SnO₂.

T. S. P.

Analysis of a Fossil Wood. F. HART (*Chem. Zeit.*, 1910, 34 168).—A fossil palm-tree, found in a bed of clay of Miocene age at Luxhaven on the Oste, a small tributary of the Elbe, gave:—

| | Insol. in HCl | | | | Soluble in HCl | | | | Alkalis |
|---|------------------|--------------------------------------|------------------|--------------------------------|--------------------------------|------|------|-----------------|-----------|
| Moisture, CO ₂ , H ₂ O* | SiO ₂ | (Al, Fe) ₂ O ₃ | SiO ₂ | Al ₂ O ₃ | Fe ₂ O ₃ | CaO | MgO | SO ₃ | and diff. |
| 14.5 | 8.21 | 51.72 | 0.26 | 0.25 | 26.50 | 2.68 | 7.04 | 0.21 | 0.23 |

* Organic matter soluble in soda was also present.

Two samples of the clay gave:

| SiO ₂ | (Al, Fe) ₂ O ₃ | CaO. | MgO. | SO ₃ | Loss on ignition. |
|------------------|--------------------------------------|------|------|-----------------|-------------------|
| 50.45 | 30.00 | 1.86 | 2.50 | 0.60 | 14.40 |
| 60.50 | 26.60 | 2.00 | 2.50 | 0.60 | 7.95 |

The ratio of silica to sesquioxides is very nearly the same in the fossil as in the first of the clay analyses (namely, 1.76 and 1.68 respectively; in the second clay analysis it is, however, 2.27); but whilst in the clay the sesquioxides are insoluble in hydrochloric acid, in the fossil they are almost wholly soluble. To explain this, it is suggested that at the time of the deposition of the clay, when this was suspended in a very finely divided state or in colloidal solution, the

cellular organic matter of the wood exerted an adsorptive action, and resolved the clay into aluminium hydroxide and hydrated silica.

L. J. S.

Barbierite, a Monoclinic Soda-felspar. WALDEMAR T. SCHALLER (*Amer. J. Sci.*, 1910, [iv], 30, 358—359).—Barbier and Prost (*Abstr.*, 1908, ii, 863) have recently established the existence of a monoclinic soda-felspar ($\text{NaAlSi}_3\text{O}_8$) isomorphous with orthoclase and dimorphous with albite. For this the name *barbierite* is proposed. The felspar from Kragerö with only 1.15% K_2O is nearly pure barbierite. Other analyses of soda-rich orthoclases have been given by Barbier (this vol., ii, 419).

L. J. S.

[Minerals in Dacite from Victoria.] ERNEST WILLINGTON SKEATS (*Quart. J. Geol. Soc.*, 1910, 66, 450—468).—In a description of the rocks of the Dandenong district, the following analyses, by Plante and Richards, are given of dacite (I) from Upway, and of the minerals isolated from this, namely, biotite (II), formula

hypersthene (III), formula $12(\text{Fe,Mg})\text{O}, (\text{Al,Fe})_2\text{O}_3, 16\text{SiO}_2$; ilmenite (IV), formula $(\text{Fe,Mg})\text{O}, 2\text{TiO}_2$.

| | SiO_2 | TiO_2 | Al_2O_3 | Fe_2O_3 | FeO | MnO | CaO | MgO | K_2O | Na_2O | H_2O | P_2O_5 | Total | Sp. G. |
|------|----------------|----------------|-------------------------|-------------------------|--------------|--------------|--------------|--------------|----------------------|-----------------------|----------------------|------------------------|-------|-----------------|
| I.* | 63.27 | 1.36 | 16.50 | 6.68 | 5.10 | 0.65 | 4.18 | 2.48 | 2.68 | 2.30 | 0.00 | 0.52 | 91.5 | 2.956 |

| IV. | 53.93 | 1.90 | 0.70 | 5.07 | 2.67 | — | 13.11 | 20.03 | 1.63 | 98.99 | — |

L. J. S.

The Nature of the Pseudonepheline from Capo di Bove near Rome. FERRUCCIO ZAMBONINI (*Rend. Accad. Sci. Fis. Mat. Napoli*, 1910, [iii], 16, 83—86).—The pseudonepheline or pseudosommite of Capo di Bove has been re-examined. The crystallography

characters agree with those of nepheline, but the refractivity is rather higher and the double refraction lower. Analysis shows:

| SiO ₂ | Al ₂ O ₃ | Fe ₂ O ₃ | CaO | Na ₂ O | K ₂ O | Total |
|------------------|--------------------------------|--------------------------------|------|-------------------|------------------|--------|
| 33.91 | 33.04 | 2.14 | 2.55 | 12.75 | 10.06 | 100.45 |

corresponding with (Na,K)AlSiO₄, whilst nepheline always contains a higher proportion of silica. Pseudonepheline has, therefore, a composition between that of kaliophillite, KAlSiO₄, and the silicate, NaAlSiO₄, which has only been obtained artificially. C. H. D.

Physiological Chemistry.

Relative Influence of the Heat and Chemical Impurity of Close Air. LEONARD E. HILL, R. A. ROWLANDS, and H. B. WALKER. The Influence of Alcohol on the Power to Hold the Breath and Work. J. F. MACKENZIE and L. E. HILL. Compressed-air Illness. I. Solubility of Compressed Air in Water and Oil. J. F. TWORT and L. E. HILL. II. The Desaturation of the Arterial Blood as Measured by the Nitrogen Dissolved in the Urine. L. E. HILL, J. F. TWORT, and H. B. WALKER. Effect of Breathing Oxygen on the Nitrogen and Oxygen of the Urine. L. E. HILL, J. F. TWORT, H. B. WALKER, and R. A. ROWLANDS (*Proc. physiol. Soc.*, 1910, iii—iv, iv, v—vi, vi—vii, viii; *J. Physiol.*, 41).—In hot closed chambers with no ventilation the discomfort is caused by moisture rather than by chemical impurities. Half an ounce of alcohol extends the time during which a man can hold his breath while performing work. Various results showing that air is more soluble in oil than water are confirmed; fat men should be excluded from caisson work. During decompression, the nitrogen in the urine sinks; the nitrogen does not get into equilibrium with the atmospheric pressure under ten to fifteen minutes. During the breathing of oxygen the renal epithelium checks its entry into the urine; some of the dissolved nitrogen can be got out of the body by this means, but not so much as was expected. W. D. H.

A Respiration Apparatus for Isolated Organs and Small Animals. OTTO COHNHEIM. The Gaseous Metabolism of the Musculature of the Small Intestine. O. COHNHEIM and DIMITRI PLETNEFF. The Gaseous Metabolism of the Stomach Musculature. O. COHNHEIM and D. PLETNEFF. The Gaseous Metabolism of the Musculature of Stomach and Intestine during Insufficient Oxygen Supply and under the Influence of Barium Chloride. O. COHNHEIM and D. PLETNEFF (*Zeitsch. physiol. Chem.*, 1910, 69, 89—95, 96—101, 102—105, 106—107).—The apparatus described was constructed on the principle of the Atwater-Benedict machine, and was used in the experiments on stomach and

intestine which follow. The intestine of cats is treated with mercuric chloride, which destroys the cells of the mucous membrane and bacteria, but leaves the muscle in active movement in Ringer's solution. This produces 80—90 mg. of carbon dioxide per 100 grams of intestine per hour, and uses up a corresponding amount of oxygen. The gaseous metabolism is furthered if oxygen is circulated direct through the capillaries. The respiratory quotient is 0.78.

In the stomach musculature in strong activity, 170—175 mg. of carbon dioxide are produced per 100 grams per hour.

In a previous research on intestinal muscle (Abstr., 1908, ii, 209) a smaller figure was given. This is due to insufficient oxygen supply, and not to the use of barium chloride in the experiments, for that salt does not affect the amount of carbon dioxide produced.

No reference is made to the work of Brodie and others on gaseous metabolism of the small intestine during rest and activity (this vol., ii, 518). The figures there given are in terms of c.c. per gram per minute. Cohnheim's figures for the intestine muscle (85 mg. of carbon dioxide per 100 grams per hour) may be reduced to the same terms and compared with Brodie's:

| | |
|---|-----------------------------|
| c.c. of carbon dioxide in intestinal muscle : | 0.0071 (Cohnheim). |
| " " " " whole small intestine at rest : | 0.02 (Brodie) |
| " " " " epithelial cells of small intestine : | 0.0318 (Brodie's estimate). |

Brodie's further estimate is taken as fairly accurate that the muscular coat accounts for 40%, and the mucous membrane of the small intestine for the remaining 60%. If 60% of the intestine is producing carbon dioxide at the rate estimated by Brodie, and the remaining 40% at the rate determined by Cohnheim, the whole intestinal wall will produce 0.25 c.c. of carbon dioxide per gram per minute; that is to say, a figure is obtained a little higher than that actually determined by Brodie and his colleagues. The correspondence is, however, very close, taking into account that in Cohnheim's experiments the muscle was in active movement.

The research illustrates again the low metabolism of muscle as compared with secreting epithelium. W. D. H.

Composition of the Blood-gases in Chloroform Anaesthesia. GEORGE A. BUCKMASTER and JOHN A. GARDNER (*J. Physiol.*, 1910, 41, 246—262).—The total gas in the blood of cats as compared to dogs is low (this vol., ii, 969); as anaesthesia deepens this is increased, and the increase is mainly due to carbon dioxide. The amount of oxygen sinks, and the blood is dark in colour; this is probably because the chloroform unites with the haemoglobin, and so prevents it combining with so much oxygen. This may explain the effect on the respiratory centre. Full analytical details are given, including the amount of chloroform in the blood. W. D. H.

The Permeability of Red Blood-corpuscles in Physiological Conditions, especially to Alkali and Alkali-earth Metals. HARTOG J. HAMBURGER and F. BUBANOVIC (*Proc. K. Akad. Wetensch. Amsterdam*, 1910, 13, 258—270).—If a disturbance within physiological limits in

the composition of the blood is produced between the corpuscles and serum, a redistribution of the inorganic constituents takes place, both as regards anions and cations. Thus, if 0.2% sodium chloride is added to serum, sodium, magnesium and calcium enter the corpuscles, and potassium leaves them. If the serum is diluted with 10% of water, sodium enters, whereas potassium, magnesium and calcium leave the corpuscles. Calcium enters the corpuscles when the blood is shaken with 5 vols. % of carbon dioxide. The fact that the corpuscles are permeable to cations is against the current view, which is based on Grüber's work. Grüber's methods and results are criticised.

W. D. H.

Comparative Investigations on the Rotatory Properties of the Plasma and Serum of Dog's Blood under Varying Conditions. I. EMIL ABDERHALDEN and PAUL KAWOHL. II. E. ABDERHALDEN and PAUL HAHN (*Zeitsch. physiol. Chem.*, 1910, 69, 1—22, 50—56).—I. Plasma has a stronger levorotatory power than serum. Repeated bleedings lower the rotation in both fluids, but the change is not a great one. Feeding on 50—500 grams of meat causes no more change than occurs without feeding; there is no rise in the rotatory power. Some preliminary experiments on feeding with carbohydrates are also given, but no noteworthy effect is seen unless large amounts of monosaccharides are given; thus laevulose raises, and dextrose depresses, the levorotation. Hunger causes considerable variations, but nothing typical. There is no difference between the optical properties of carotid and jugular blood, but the portal blood has always a higher rotation than that from other parts.

II. Injection of dextrin into the blood stream lowers the levorotation, but the effect passes off in about twenty minutes. The lowering of rotation produced by bleeding lasts longer in fasting than in well-fed animals.

W. D. H.

The Influence of Large Quantities of Water on the Optical Properties of Blood-plasma and Serum. EMIL ABDERHALDEN and ERNST RUEHL (*Zeitsch. physiol. Chem.*, 1910, 69, 57—59).—Large quantities of water were given by the alimentary canal, and this caused a noteworthy sinking of the rotatory power of the plasma and serum; this lasts for about four hours.

W. D. H.

A Method for Drying Serum. SIGMUND FRÄNKEL and ALADAR EIFFER (*Biochem. Zeitsch.*, 1910, 28, 330—331).—Attempts by various methods of evaporation do not yield good results. A perfectly dry powder was obtained by the addition of anhydrous sodium sulphate (670 grams per litre of ox-serum).

W. D. H.

Autolysis of Normal Blood. J. C. SCHIFFERS (*Biochem. Zeitsch.*, 1910, 28, 418—426).—Defibrinated blood undergoes autolysis, which is accelerated by acetic acid; proteoses, leucine, and tyrosine were found in the autolysed fluid. The active agent is destroyed by heat. The change is believed, however, to be, in part, due to a spontaneous cleavage of the protein molecule. Blood-serum shows no autolysis, but the red corpuscles do.

W. D. H.

Hæmolysis. II. Hæmolysis by Sodium Carbonate. OSKAR GROS (*Arch. exp. Path. Pharm.*, 1910, 63, 341—346. Compare this vol., ii, 51).—Hæmolysis produced by sodium carbonate runs on the same lines as that caused by ammonia. Within definite limits of concentration, the time of induction is inversely proportional to the concentration of the salt, and proportional to the amount of blood.
W. D. H.

The Hydrochloric Acid of the Gastric Juice of the Selachian Fishes. ERNST WEINLAND [with A. GROHMANN and TH. STEFFEN] (*Zeitsch. Biol.*, 1910, 55, 58—69).—The method of Sjöqvist for estimating hydrochloric acid is not practicable in the presence of chlorides of the alkali earths. Hydrochloric acid is found even though none be present in the free state if an organic acid is present also. The gastric juice of the dog fish and other selachians contains little or no free hydrochloric acid. Statements to the contrary are due to the non-recognition of the two facts mentioned above.
W. D. H.

Variations in Quantity and Composition of the Pancreatic Juices during Secretions Provoked by Secretin. S. LAJOG (Compt. rend., 1910, 151, 824—827).—Repeated injection of secretin into dogs enables a regular supply of the pancreatic fluid to be obtained during several hours. The alkalinity and diastatic activity of the juice thus obtained gradually diminishes, however, the variation in lipolytic power being more marked than the diminution in tryptic or amylolytic activity.
W. O. W.

Physiology of Digestion. II. Total Chlorine of the Animal Body. RUDOLF ROSEMANN (*Pflüger's Archiv*, 1910, 135, 177—193. Compare Abstr., 1907, ii, 706).—The author's previous work on the hydrochloric acid of the gastric juice led to the present research. The methods used and results obtained by previous workers are summarised. The fetus is richer in chlorine than the new-born animal, and the percentage amount diminishes still more after birth. The author's values for the fully-grown dog average 0.12% of chlorine. In the cat and mouse, the figure is a little higher.
W. D. H.

Metabolism Experiments as Statistical Problems. H. L. RIETZ and H. H. MITCHELL (*J. Biol. Chem.*, 1910, 8, 297—326).—Metabolism experiments should be studied mathematically, as observations on heredity are, in order to exclude the deviations which occur in physiological processes, and take place although surrounding conditions are made as constant as possible.
W. D. H.

Metabolism of Development. II. Nitrogen Balance during Pregnancy and Menstruation in the Dog. JOHN R. MURRAY (*Amer. J. Physiol.*, 1910, 27, 177—205. Compare this vol., ii, 729).—Menstruation causes a retention of nitrogen, which is to be regarded, in part, as a compensation for the blood lost. The first half of normal pregnancy is characterised by a loss of nitrogen from the mother's body. This is probably due to the action of proteolytic enzymes

produced by the embryo and not yet limited by the placenta in their action to the maternal blood. Nitrogen retention occurs in the last half of the pregnancy.

W. D. H.

The Importance of the Mechanical Part of the Work of Digestion in Relation to Metabolism in the Ox. KARL DAHM (*Biochem. Zeitsch.*, 1910, 28, 456—503).—A very important contribution to the much discussed question as to whether the work of the digestive organs is an important factor in metabolism, as Zuntz maintains, or not. A number of oxen were fed on different diets, and their metabolism and heat production determined by examining faeces, urine, and gaseous interchanges. The results confirm Zuntz's views.

W. D. H.

Digestion of Cellulose in Dogs, and the Methods for Estimating Cellulose. HANS LOHRISCH (*Zeitsch. physiol. Chem.*, 1910, 69, 143—151).—The author's previous conclusion that dogs are able to digest cellulose, he finds on further work to be incorrect. Dogs do not digest cellulose. He still holds, however, that cellulose is digestible to some extent by man in spite of the criticisms of Scheunert. The Simon-Lohrlich method for the estimation of cellulose is regarded as the best.

W. D. H.

The Work of Digestion after Carbohydrate Food, and its Dependence on the Physical Condition of the Nourishment. OTTO MÜLLER (*Biochem. Zeitsch.*, 1910, 28, 427—455).—Investigations on the gaseous metabolism of dogs show that this is much more increased by giving starch than by giving an equivalent amount of dextrose; the effect is also more prolonged after starch feeding. Older investigations on the question, in which the gaseous interchanges were not examined, are criticised. The original paper must be consulted for full analytical details and methods for calculating results; the main conclusion is that in starch feeding, for every 100 calories of the starch digested, 9.23 calories are produced over and above the nanition figure; for dextrose the figure is only 5.61. When the carbohydrates are given in small quantities, the difference is not noticeable. The low respiratory quotient found is due to the fact that the animals had fasted for two days before the experiment, therefore much of the carbohydrate given would be stored as glycogen, and fat used for combustion.

W. D. H.

Carbohydrate Metabolism in *Carcinas mænas*. E. GRAF VON SCHÖNBORN (*Zeitsch. Biol.*, 1910, 55, 70—82).—In the crabs investigated, glycogen is found in important amounts; after twenty-five days' nanition, it does not wholly disappear; its amount diminishes at first rapidly, then slowly. On then feeding upon fish, or injecting dextrose, it is again laid on until its amount may reach 2.7% of the body-weight. In the period of chitin formation in the shell, the amount of glycogen is lessened.

W. D. H.

The Influence of Carbohydrate and Fat on Protein Metabolism. II. The Effect of Phloridzin Glycosuria. E. PROVAN CATHCART and M. ROSS TAYLOR (*J. Physiol.*, 1910, 41, 276—284).—In phloridzin glycosuria, if the carbohydrate in the food is insufficient, there is no excretion of creatine. The carbohydrate cannot be replaced by fat. The output of creatine persists only as long as the glycosuria lasts. There is no apparent causal relationship between acidosis and excretion of creatine. The experiments were made on dogs. W. D. H.

Parenteral Administration of Protein. KORNÉL VON KÖRÖS (*Zeitsch. physiol. Chem.*, 1910, 69, 313—326).—If a foreign protein is injected into the circulation, it has been held that provided circulation through the alimentary canal is prevented, it passes like a foreign substance into the urine. This is not the case, proteins and proteoses pass into the urine in minimal amounts only, even though the stomach and intestine are extirpated. The injected protein remains therefore in the organism, but whether it is built into the tissues as is protein given enterally is as yet an open question. W. D. H.

Metabolism Experiments with Elastin. EMIL ADDEHOLDEN and ERNST RUEHL (*Zeitsch. physiol. Chem.*, 1910, 69, 301—309).—Elastin contains glycine in abundance, leucine, and very little glutamic acid; histidine has been found in so-called hemi-elastin, but tryptophan is absent. In the present research on dogs, elastin was prepared from the neck ligament of the ox; on artificial gastric digestion, hemi-elastin was obtained, but tryptophan was present, although whether this was due to impurities is doubtful. It is badly absorbed, the faeces containing a high percentage of nitrogen; the animals lost weight, and elastin is regarded as inferior to other proteins, although it “spares” them to some extent. It is superior to gelatin. After feeding on elastin, Borchardt (*Abstr.*, 1908, ii, 957) stated that hemi-elastin was discoverable in the blood and urine; these experiments were repeated with a wholly negative result. W. D. H.

The Assimilation of Natural and Artificial Nourishment. II. ARNOLD ORGLER (*Biochem. Zeitsch.*, 1910, 28, 359—373).—Puppies of the same litter were fed, some on cow's milk, and some on their mother's milk. They were killed and analysed, some at four and some at six weeks of age. Those fed in the natural way grew more rapidly in weight and strength than the others, and their bodies contained more fat, nitrogen, ash, and calcium. The puppies fed on cow's milk took it freely, and were found with enlarged stomachs after death. The putting on of fat per kilo. of body-weight was more rapid than in those artificially fed. If the figures are reckoned on the fat-free body, the naturally-fed animals show a higher percentage of dry residue, but the nitrogen, ash, and calcium are about equal in the two sets of animals. Dog's milk is richer than cow's milk in protein and ash, and is of greater calorific value. Analytical details are given in full, and compared with those of previous workers. W. D. H.

Distribution of Fluorine in the Human Organs. EMIL ZDAREK (*Zeitsch. physiol. Chem.*, 1910, 69, 127—137).—Fluorine is widespread in the organs; the quantity is always small, and is relatively greatest in liver, kidneys, and bone. Analyses are given in full. W. D. H.

Detection of Phosphates [in Tissues] with the Molybdate Reagent. RAPHAEL ED. LIESEGANG (*Chem. Zeit.*, 1910, 34, 1158).—Experiments showing that for histological purposes the application of the ammonium molybdate-nitric acid reagent does not localise the phosphates in tissues. L. DE K.

Incineration of Microtome Sections. RAPHAEL ED. LIESEGANG (*Biochem. Zeitsch.*, 1910, 28, 413—417).—An attempt was made in the direction of localising the occurrence of certain elements in microscopic section by incinerating them. In the early stages of heating, the blackening indicates the position of carbonaceous material, and here, as also in the later stages of complete incineration, it is still possible to identify the tissue elements, especially in thin sections. Attempts thus to localise iron microchemically were not successful, as the iron is again "masked" as oxide. A similar failure attended attempts to localise iodine in the thyroid, and the various reactions for the detection of phosphorus are either not sufficiently characteristic or worthless. W. D. H.

The Aldehydase in Animal Tissues. FR. BATELLI and LINA STERN (*Biochem. Zeitsch.*, 1910, 29, 130—151).—By aldehydase is meant the ferment which can convert an aldehyde into a mixture of the corresponding alcohol and acid. In the absence of oxygen the activity can be measured by estimating the amount of acid produced. In the presence of oxygen, certain aldehydes are oxidised further to the acid, although in many tissues the amount of alcohol-oxydase is very small. Acetaldehyde is changed in most tissues more rapidly than salicylaldehyde. Calf's spleen is an exception in this respect. Formaldehyde does not readily undergo the change. The aldehydase is contained in most tissues, especially in the liver of the horse. Preparations containing aldehydase can be produced by precipitation of the tissues by acetone. The ferment acts best in slightly alkaline medium, the optimum temperature being 60°. The rate of reaction was also studied. S. B. S.

Lipoids of the Brain. II. A New Method for the Preparation of the Galactosides and of Sphingomyelin. OTTO ROSENHEIM and M. CHRISTINE TEBB (*Proc. physiol. Soc.*, 1910, 1—11; *J. Physiol.*, 41. Compare Abstr., 1909, i, 282).—Cholesterol is first removed by extraction with cold acetone, and then lecithin and kephalin by extraction with ether or light petroleum; the residue is then reduced to a fine powder, and extracted with cold pyridine; the extract is reddish in colour, and shows an absorption spectrum similar to that of hæmochromogen; it is poured into acetone, and a hunky precipitate of impure galactosides (phrenosin and kersin) is thus

obtained; these can be separated by fractional crystallisation from 85% alcohol at 30° and 0°, and subsequently purified by several methods. If the residue is now extracted with warm pyridine (40—45°), sphingomyelin is dissolved out, which is precipitated by cooling to room temperature, and subsequently purified. Molisch's reaction is a very delicate one for the detection of the galactosides.

W. D. H.

Lipoids. XIII. Composition of the Spinal Cord. SIEMUND FRÄNKEL and LUDWIG DIMITZ (*Biochem. Zeitsch.*, 1910, 28, 295—319).—The spinal cord contains 74% of water, 18% of lipoids (being the part of the central nervous system richest in these substances), and 8% of the proteins described by Halliburton, who, however, put the percentage higher. The amount of water increases with age. The cholesterol present (4%) is in the free condition, as in the brain. A great part of the unsaturated phosphatides consists of cephalin; the saturated lipoids are only present to the extent of 1.5%.

W. D. H.

Union of Certain Poisons with Cardiac Muscle. HORACE M. VERNON (*J. Physiol.*, 1910, 41, 194—232).—Alcohol added to Ringer's fluid perfused through the tortoise heart lessens the amplitude of the heart's contraction; after about twelve minutes, the amplitude remains at a small, but constant, level; this effect is removed by perfusing with pure Ringer's solution. Ether and chloroform act in the same way, but smaller doses are required to produce the same effect as alcohol; their action is also reversible; the concentration of the poison does not affect this result. Hydrocyanic acid acts in the same way, except that the effect is not proportional to the concentration; greater concentrations than 0.01% permanently injure the heart. Probably the same amount of poison is united to the cardiac substance in spite of variations in its concentration. Sodium fluoride acts somewhat in the same way; on washing out with pure saline, the ventricle usually shows one to three huge waves of tonus oscillation. Formaldehyde very slowly reduces the contractions to a constant level, proportional to the concentration (0.001 to 0.008%), and recovery on washing out is very slow. Alcohol, ether, and chloroform slow, and may stop, the heart. Formaldehyde, hydrocyanic acid, and sodium fluoride seldom stopped the heart absolutely, and in many experiments did not affect its rate. Hearts depressed in vitality are more sensitive to the action of poisons, especially of chloroform. It is regarded as probable that alcohol, ether, and chloroform enter into a loose union with the colloidal lipoids or other constituents of the cardiac tissue by means of molecular valencies, whilst hydrogen cyanide, sodium fluoride, and formaldehyde enter into definite chemical combination by means of atomic valencies.

W. D. H.

Autolysis. WALTHER LINDEMANN (*Zeitsch. Biol.*, 1910, 55, 36—52).—Autolysis in the livers of rabbits, cats, and dogs was studied under aseptic conditions. Protein hydrolysis, acid formation, and development of gas occur only if the organs are kept at 37°.

Carbon dioxide and hydrogen appear in most variable proportions; hydrogen may be absent in the case of the rabbit. No constant relation-ship was found between the production of carbon dioxide and volatile fatty acids; this is against a fatty acid fermentation of carbohydrate. The possibility of the acids arising from protein was shown by the occurrence of de-amidation.

W. D. H.

The Behaviour of the Fat of Organs in Autolysis, and on Preservation Under Aseptic Conditions. KOHSHI OHTA (*Biochem. Zeitsch.*, 1910, 29, 1—12).—To investigate the question as to whether fat can be formed from proteins, liver and heart muscular tissues were preserved in the cold and at 37—40° with chloroform water, and the amounts of fatty acids in the unchanged tissues, together with the cholesterol in the changed and unchanged tissues, were estimated. It was found that there was no increase of fatty acid produced under any conditions in the liver tissue, whereas the results in the heart muscular tissue were irregular, probably owing to the want of homogeneity in the original tissue. Owing to the small quantities of cholesterol, and the consequent uncertainties due to experimental error, no conclusion could be drawn as to whether this substance increases in amount or not.

S. B. S.

The Oxidation Processes of Lipoids of the Spinal Column. E. SIGNORELLI (*Biochem. Zeitsch.*, 1910, 29, 25—30).—It has already been shown by Scaffidi that the nervous tissue, especially during degeneration, absorbs relatively large amounts of oxygen. The author now shows that the lipoids prepared from fresh nervous tissue also absorb oxygen, owing probably to the presence of unsaturated lipoids. The experiments were carried out by means of a microspirometer.

S. B. S.

The Amount of Erepsin in Blood-free Organs. OTTO CORNHIEIM and DIMITRI PLETNEFF (*Zeitsch. physiol. Chem.*, 1910, 69, 108—112).—Vernon found the duodenal mucous membrane to be richest in a peptolytic enzyme (erepsin), whilst among the organs, the kidneys possessed most and the blood least. He determined this colorimetrically by the biuret test. Abderhalden uses the splitting off of tyrosine from glycyl-tyrosine as his test for such enzymes. In the present research a slight modification of Vernon's method was employed to test the presence of erepsin in cat's organs (kidneys, lungs, muscles); the results confirm those of Vernon; the organs were freed from blood by Ringer's solution. Erepsin, or, at any rate, a peptolytic enzyme, is therefore present in the tissue cells independently of the blood.

W. D. H.

The Isolated Kidney. The Influence of Pulse Pressure upon Renal Function. DONALD R. HOOKER (*Amer. J. Physiol.*, 1910, 27, 24—44).—A perfusion apparatus for the dog's kidney is described, which yields a pulsatile wave of pressure similar to the normal pulse. The amount of urinary filtrate and the rate of blood flow vary directly as the magnitude of the pulse pressure; the amount of

protein varies inversely as this magnitude; in all cases the mean perfusion pressure was constant.

W. D. H.

The Cortex of the Suprarenal Body. K. KAWASHIMA (*Biochem. Zeitsch.*, 1910, 28, 332—339).—Extracts of the cortical region of the horse's suprarenal contain no enzyme capable of destroying adrenaline. Small quantities of adrenaline or a related substance are present.

W. D. H.

The Behaviour of the Chromaffine Substance of the Suprarenal Body in Hunger and Under the Influence of Potassium Iodide. F. VENULET and G. DMITROWSKY (*Arch. exp. Path. Pharm.*, 1910, 63, 460—464).—In inanition, the chromaffine substance of the suprarenal is diminished; administration of adrenaline under these conditions prolongs life. Potassium iodide is inhibitory towards the secretion of adrenaline, and this in addition to its depressor action is considered to explain its therapeutic use in arteriosclerosis.

W. D. H.

The Peptide-splitting Enzyme of Ovaries. A. KOBLENCZ and WALTHER LÖB (*Biochem. Zeitsch.*, 1910, 29, 102—103).—The ovaries of rabbits and pigs contain an enzyme capable of hydrolysing glycyl-tryptophan.

S. B. S.

Changes in the Skin following the Application of Local Anæsthetics. I. Ethyl Chloride. SHEPHERD IVORY FRANZ and WILLIAM C. RUEDIGER (*Amer. J. Physiol.*, 1910, 27, 45—59).—Ethyl chloride is an anæsthetic and analgesic; analgesia (insensibility to pain) being the more persistent. This is in favour of the view that pain is a sensation subserved by nerve- and end-organs distinct from those concerned in tactile impressions. Sensations of temperature are dulled.

W. D. H.

Laxatives and the Calcium of the Intestine. RICHARD CHIARI (*Arch. exp. Path. Pharm.*, 1910, 63, 434—440).—Saline purgatives which precipitate calcium ions increase the calcium in the intestinal wall, and calomel and alkaloids lessen it.

W. D. H.

Is the Stoppage of Rhythmic Contractions in a Solution of Pure Sodium Chloride Due to Increased Rate of Oxidation? JACQUES LOEB and HARDOLPH WASTENEYS (*Biochem. Zeitsch.*, 1910, 28, 350—352).—Direct measurements show that there is no increased absorption of oxygen due to the presence of sodium chloride in solutions containing organisms which undergo rhythmic contractions, so that the question in the title is answered in the negative. The retarding action of sodium chloride on the rhythmic contractions of *Medusa* is not removed by addition of sodium cyanide.

G. S.

Production of Light by the Firefly. JOSEPH H. KASTLE and F. ALEX. McDERMOTT (*Amer. J. Physiol.*, 1910, 27, 122—151).—Three things are concerned in the production of light by living organisms: the

photogenic substance, water, and oxygen. The first is characterised by extreme irritability, but its composition is unknown. Chemical stimuli, especially ether, chloroform, carbon disulphide, carbon tetrachloride, nitrobenzene, and nitrites of certain metals, cause a continuous formation of light in the firefly, whereas normally light emission is intermittent, resembling a series of luminous explosions. Of the substances tried, sulphur dioxide is the most toxic. Great diminution of atmospheric pressure causes emission of light in the living animal and in the detached luminous organ. The photogenic material can be dried in a vacuum, and retains its power to emit light when moistened for at least thirteen months. W. D. H.

The Secretion of the Infundibular Lobe of the Pituitary Body and its Presence in Cerebrospinal Fluid. HARVEY CUSHING and EMIL GOETSCH (*Amer. J. Physiol.*, 1910, 27, 60—86).—The view that the active principle of this gland is secreted into the ventricular cavity is supported by the discovery that the cerebrospinal fluid contains a substance which acts on blood-pressure like "pituin." This can be demonstrated in concentrated specimens of the fluid. Pituin is believed to be a product of the hyaline substance of the *pars nervosa*. W. D. H.

The Reducing Properties of Milk, Liver, and Yeast. LEOPOLD ROSENTHALER (*Zeitsch. Nahr. Genussm.*, 1910, 20, 448—453).—From the results of experiments in which the action of milk on phenylglyoxylic acid was investigated, the author comes to the conclusion that the reducing power of milk on such substances as the methylene-blue of Schardinger's reagent (*Abstr.*, 1903, ii, 190), etc., is due to bacterial action, and not to that of enzymes. The analogous actions of liver and yeast are due to the same cause. W. P. S.

Aporrhagma. D. ACKERMANN and FRIEDRICH KUTSCHER (*Zeitsch. physiol. Chem.*, 1910, 69, 265—272).—The name aporrhagma is given to the decomposition products of protein amino-acids formed by physiological processes in the living plant or animal, and includes the common ptomaines and acids formed by putrefaction.

Attention is drawn to the fact that although methylated nitrogenous compounds are present in large quantities in vegetable tissues, they are rarely met with in animal tissues. Methylated glycine has been extracted from the muscles of *Crangon vulgaris*, *Astacus fluviatilis*, and *Acanthias vulgaris*, but does not appear to be present in the muscle of mammals. It is suggested that in warm-blooded animals the nitrogenous products are got rid of by processes of oxidation, but that in plants and cold-blooded animals they are removed by means of complete methylation. Methylation can occur in the case of warm-blooded animals when oxidation is stopped to an appreciable extent, for example, in cases of phosphorus poisoning.

A list of aporrhagma and their corresponding amino-acids is given, and also a list of methylated aporrhagma. J. J. S.

A New Aporrhagma Prepared by Bacterial Agencies. D. ACKERMANN (*Zeitsch. physiol. Chem.*, 1910, 69, 273—281. Compare this vol., i, 419).—Lysine mixed with Witte's peptone and dextrose

undergoes bacterial putrefaction in the presence of a small amount of putrefying pancreas, and, after nineteen days at 36° , yields appreciable amounts of pentamethylenediamine, which can be isolated as the picrate or aurichloride. A small amount of a product which yields a readily soluble platinichloride is also formed.

Arginine under similar conditions yields tetramethylenediamine and δ -aminovaleric acid, but not agmatine, and glutamic acid yields γ -amino-butyric acid (compare Schotten, Abstr., 1883, 813; Gabriel, *ibid.*, 1896, 360), by the elimination of carbon dioxide.

It has not been found possible to isolate methylamine* and ethylamine from the products formed by the action of anaerobic bacteria on glycine and alanine.

J. J. S.

A Methylated Aporrhagma from Animal Tissues. R. ENGELAND and FRIEDRICH KUTSCHER (*Zeitsch. physiol. Chem.*, 1910, 69, 282—285).—The γ -aminobutyric acid obtained from glutamic acid (compare Ackermann, preceding abstract) is identical with the synthetical acid. The aurichloride, $C_4H_9O_2N, HAuCl_4$, crystallises in glistening plates, m. p. 138° .

When methylated, the γ -amino-acid yields a product from which an aurichloride, $C_7H_{16}O_2N, HAuCl_4$, can be obtained, identical with the aurichloride, m. p. 203° , from γ -butyrobetaine chloride isolated by Takeda (this vol., ii, 797) from the urine of dogs poisoned by phosphorus. The platinichloride of the ethyl ester,

has m. p. 222° (decomp.). The occurrence of this betaine in substances of animal origin is due to the decomposition of glutamic acid and the methylation of the γ -aminobutyric acid. The α -hydroxy- γ -butyrobetaine formed in muscle extract is probably the first oxidation product of γ -butyrobetaine.

J. J. S.

Distribution of Nitrogen in the Intestinal Excreta. HENRI LABBÉ (*Compt. rend.*, 1910, 151, 822—824).—Normal human faeces were extracted successively with ether, benzene, aqueous sodium carbonate, and glacial acetic acid. Nitrogen was determined in the original faeces, in each extract, and in the insoluble residue. The results are given in tabular form. The benzene extract appeared to contain the substances of the lecithin type, whilst the alkaline extract probably contained the amino-acids.

W. O. W.

The Secretion of Urine. JOSEPH BARCROFT and HERMAN STRAUB (*J. Physiol.*, 1910, 41, 145—167).—The diuretics studied fall into two groups: (1) those which produce urine without alteration in the gaseous exchange of the kidney (Ringer's solution, and sodium chloride in hyper- and hypo-tonic solutions); (2) those which cause increased gaseous exchange (urea, caffeine, sodium sulphate, phloridzin). In the case of urea and caffeine there is a definite poisoning action, as shown by subsequent depression of the gaseous exchange. The distinctive features of the urine produced by the second class are attained by a process of secretion on the part of the tubules, and not by a process of re-absorption. After poisoning the cells by corrosive

sublimate or by the diuretics of the second class, a flow of urine can still be produced by the first class of diuretics; the urine so produced appears to be isotonic with the blood-serum. Clamping the kidney vessels for fifteen minutes after washing out with Ringer's solution does not abolish its power of secretion. The special interest of the research is the action of diuretics of the first class, and those produce urine independently of secretory activity (as judged by the absence of increased metabolism), and so their action must be attributed to mechanical filtration; the experimental methods adopted were such that changes in rate of blood flow or of blood pressure could be excluded. The proteins of the blood-plasma in virtue of their osmotic pressure would attract water into the blood; the capillary pressure would drive water into the urine. Suppose, for instance, that the capillary pressure is equal to 27 mm. of mercury, and that the osmotic pressure of the proteins is a little lower, say, 25, as it probably is in normal circumstances, then the available pressure for filtration would be 2 mm. If the amount of protein in the blood-plasma were reduced to half, the osmotic pressure will be reduced to 12.5, and the available filtering pressure is thus 14.5, or seven-fold increase, and diuresis will occur. This argument was justified by testing it as follows: the animal was bled very considerably, and the blood replaced by Ringer's solution containing blood corpuscles in suspension; the diuresis so produced was very considerable, although the blood pressure was very low, and this was attended with no increase in the gaseous exchange.

W. D. H.

A Comparison of the Total Nitrogen Excretion of either Kidney in Normal Individuals. THEODORE E. BARRINGER, jun., and BENJ. S. BARRINGER (*Amer. J. Physiol.*, 1910, 27, 119—121).—Observations were made on eleven young men. One ureter was catheterised, a bladder catheter collecting the urine from the other kidney. Details are given of the quantity of urine, in periods varying from twenty to one hundred and twenty minutes, secreted by each kidney, also the total nitrogen, and the sum of urea and ammonia nitrogen. The differences noted are usually small.

W. D. H.

The Excretion of Parenterally Administered Creatine in Mammals. CORNELIS A. PEKELHARING and C. J. C. VAN HOOGENHUYZE (*Zeitsch. physiol. Chem.*, 1910, 69, 395—407).—Injection of creatine into the blood-stream of rabbits, led to the result that this substance is, in part, decomposed in the body, and partly excreted as creatinine by the kidneys. The liver appears to be specially concerned in its destruction and in its conversion into creatinine.

W. D. H.

The Excretion of Organically United Phosphorus in Urine. KURA KONDO (*Biochem. Zeitsch.*, 1910, 23, 200—207).—Previous work on the organic phosphorus compounds of the urine in health and disease have shown that they are increased by the administration of glycerol-phosphates and lecithin. In the present research, a dog was fed on horse-flesh and lard, and then to this were added for two or three days' periods, brain, casein, and thymus. On normal days the

organic phosphorus in percentage parts of total phosphorus averaged 2.7, on the brain days 3.3, and on the casein and thymus days 1.5. W. D. H.

The Influence of the Fat of the Food Ingested on the Excretion of the Acetone Substances. GUNNAR FOSSNER (*Chem. Zentr.*, 1909, ii, 1759; from *Skand. Arch. Physiol.*, 1909, 22, 349—392).—The excretion of acetone and β -hydroxybutyric acid depends on the food ingested. After meals there is a regular increase in the excretion of acetone substances, and the missing of a meal causes a distinct change in the regular curve representing the excretion, and a marked diminution in the amounts excreted. The excretion depends on the fat ingested; no difference could be detected between the action of the higher fatty acids (lard, etc.) and the lower fatty acids (hutter). When the store of glycogen in the body had diminished, relatively small quantities of fat caused acidosis, similar to that of severe diabetes. S. B. S.

The Influence of Muscular Work on the Excretion of Acetone Substances, with Diets Poor in Carbohydrates. GUNNAR FOSSNER (*Chem. Zentr.*, 1909, ii, 1760; from *Skand. Arch. Physiol.*, 1909, 22, 393—406).—On different days, certain amounts of muscular work were performed (marching), which were in the ratios of 1, 2, 3, and 4. The average diet consisted of 111.7 grams protein, 239 grams fat, and 59.4 grams carbohydrates. Muscular work was found to diminish the body reserve of carbohydrates, which are concerned in the formation of acetone substances. This diminution was, however, only proportional to the amount of work performed within certain limits. The maximal action under the condition of experiments was attained by a forced march lasting for two to thirty-six minutes. S. B. S.

Melanuria. HANS EPPINGER (*Biochem. Zeitsch.*, 1910, 28, 181—192).—The origin of the black pigment which occurs in certain malignant tumours and passes into the urine is obscure, and the suggestion that it originates from tyrosine by the action of a tyrosinase is due to experiments *in vitro* only. The present research shows that this pigment (melanin) originates from tryptophan. By feeding with tryptophan, the excretion of the pigment is increased three-fold, whereas tyrosine and phenylalanine, the parent substances of homogentisic acid, have no effect. The urine is sometimes darkly coloured when passed, sometimes the darkening comes on after exposure to the air, but in all cases of melanotic tumour, it appears on the addition of oxidising agents; the material in the urine is then not melanin, but melanogen. This can be precipitated from the urine with sulphuric acid and mercuric sulphate, and can then be dissolved out from the precipitate by a method which is described in full, and finally obtained in crystalline form. These crystals show all the colour and other reactions of melanogen as contained in the original urine. The following formula was calculated from its percentage composition: $C_6H_{12}O_4N_2S$, and it is regarded provisionally as a hydroxy- γ -methylpyrrolidinedicarboxylic acid in the form of an ethereal sulphate. Another

substance was separated from the same urine; it is probably related to the first, but this requires further investigation. W. D. H.

Acapnia and Shock. VII. Failure of the Circulation. YANDELL HENDERSON (*Amer. J. Physiol.*, 1910, 27, 152—176. Compare this vol., ii, 622).—The essential factor in the circulation in shock is not heart failure, but failure of the veno-pressor mechanism, which consists, in part, of the tonus of the tissues and, in part, of osmotic processes. Tonus is largely dependent on the carbon dioxide they contain, and when the tension of carbon dioxide (regulated by the respiratory centre) is diminished in acapnia, the blood stagnates in the venous reservoirs. Acapnia upsets osmotic processes; water passes out of the blood into the tissues, and is ultimately followed by tissue asphyxia and acidosis. W. D. H.

The Fundamental Constituents of Tumour Cells. EMIL ADDERHALDEN and FLORENTIN MEDIGRECEANU (*Zeitsch. physiol. Chem.*, 1910, 69, 66—71).—Tyrosine, glutamic acid, and glycine were estimated in the cell proteins derived from various malignant tumours. The different kinds of tumours all yielded the three amino acids in approximately the same proportion. W. D. H.

The Theory of the Wassermann Reaction. E. GATZ and R. INABA (*Biochem. Zeitsch.*, 1910, 28, 374—391).—Sachs and Rondoni have shown that dilution of the alcoholic extract of the syphilitic liver with salt solution causes a cloudiness, which varies as the dilution is effected slowly or rapidly. The manner of dilution influences the power of the extract in uniting with complement, and they explain this as due to a physical cause, namely, the size of the particles in suspension. There is an undoubted alteration as Sachs and Rondoni described, and this disappears on cooling; moreover, the difference does not run parallel to the change in hæmolytic power; the latter, however, does not remain unaltered. Sharper results are obtained in extracts diluted slowly, and those who use the Wassermann reaction for the biological detection of syphilis must recognise the importance of this factor. It appears doubtful if the explanation is wholly physical. W. D. H.

Serological Studies with the Help of the Optical Method.
XI. Parenteral Administration of Carbohydrates. EMIL ADDERHALDEN and GEORG KAPFERBERGER (*Zeitsch. physiol. Chem.*, 1910, 69, 23—49).—Sucrose injected either into the blood or subcutaneously is inverted in the blood, but great differences are seen in different animals. Lactose is also affected, but not raffinose. After the injection of lactose, dog's serum or plasma inverts sucrose and lactose, but not raffinose. The action of these fluids on the two disaccharides is noticeable seven to eight hours after a subcutaneous injection of either, and lasts at least fourteen days. Whether the urine has the same power has not yet been investigated. The agent in the blood that acts on the sugars, dialyses into distilled water. A temperature of 60° destroys the power, and of 4° lessens it. W. D. H.

The Influence of Pharmacological Agents on Oxidation in the Organism. JULIUS BAER and WILHELM MEYERSTEIN (*Arch. exp. Path. Pharm.*, 1910, 63, 441—459).—The importance of oxidation as a source of energy, and the way in which body functions are influenced by drugs acting on oxidation processes are well illustrated by recent work on narcosis. In the present research, the point investigated was acetone formation in the liver perfused with various drugs: namely, potassium cyanide, chloral hydrate, trichloroacetic acid, dimethylbarbituric acid or ethylbarbituric acid (veronal), salicylic acid, salicylaldehyde, saligenin, *p*-hydroxybenzoic acid and aldehyde, and *m*-hydroxybenzoic acid and aldehyde. All of these inhibit acetone formation in varying degrees, but the figures given show that the variation is not proportional to their effect on oxidation; indeed, some increase oxidative processes. In the oxidation of butyric and hydroxybutyric acids in the liver, two different processes or factors have therefore to be dealt with.

W. D. H.

Behaviour of Phloridzin after Extirpation of the Kidneys. ERICH LESCHKE. Answer to the Preceding. KARL GLAFSENDA and ERNST P. PICK (*Pflüger's Archiv*, 1910, 135, 171—175, 176. Compare this vol., ii, 530).—Polemical. Both sides maintain their original position.

W. D. H.

Quantitative Investigations on the Chemistry of Strophanthin Action. WALTHER STRAUB (*Biochem. Zeitsch.*, 1910, 22, 392—407).—Alkaloids which act on certain organs, such as the heart, can be washed out and re-obtained in the washings, and their action is thus reversible. This is not the case with the digitalis glucoside. Strophanthin is in this relation similar to alkaloids, and its action is largely reversible. Tested on a frog's heart by perfusion, the reaction is proportional to the concentration of the drug, and there is probably a chemical action between the cell constituents and the glucoside, although very little of the latter is used in the combination or interaction, and there is no storage in the heart muscle.

W. D. H.

The Systolic and Diastolic Heart-Action of Strophanthin. N. WERSCHNIN (*Arch. exp. Path. Pharm.*, 1910, 63, 386—404).—This drug in Ringer's solution applied to the exterior or interior of the frog's heart leads in small concentrations to diastolic stoppage, in medium doses to systolic stoppage, and in high concentrations to diastolic stoppage and paralysis. Mixed with blood-serum, the toxic power is much increased. This is, in part, due to the lipoids present, and lecithin exerts a similar action, but the effect in producing systolic stoppage appears to be specially due to the salts of the serum, particularly those of calcium, but calcium salts only exert this influence when applied endocardially.

W. D. H.

The Action of Strophanthin on the Blood-Vessels. MAX KASZTAN (*Arch. exp. Path. Pharm.*, 1910, 63, 405—423).—The effect of members of the digitalis family in raising arterial pressure is, in part, due to vaso-constriction, and large doses will soon contract the

kidney blood-vessels and lessen the flow of urine. The present research specially takes up this point, and the organs of cats, rabbits, and dogs were perfused with strophanthin in Ringer's solution. Solutions of one or more per million constrict the blood-vessels of kidney and intestine; concentrations below this dilate them, but here a difference between the kidney and intestine is noted, for smaller concentrations, which constrict the intestinal, will still dilate the kidney blood-vessels.

W. D. H.

[Physiological] Action of Atropine, Pilocarpine, and Physostigmine. ARTHUR R. CUSHNY (*J. Physiol.*, 1910, 41, 233—245).—Pilocarpine causes contraction or inhibition of the cat's uterus, according to the condition of the organ, in this resembling the effects of adrenaline or hypogastric stimulation. Its contractor action is antagonised by ergotoxine, as is that of adrenaline or electric stimulation. It differs from adrenaline in being antagonised completely by atropine whether it contracts or inhibits the uterus. Physostigmine contracts the uterus, and is antagonised by atropine. It is suggested that pilocarpine and atropine act on receptive substances associated with the nerve impulse path to the uterus, but do not lie actually on this path. Physostigmine may probably affect the receptors associated with the augmentor path only. In the case of other abdominal organs, the same explanation is regarded as tenable, whilst, in other cases, the receptive substances are regarded as lying on the impulse path, since this is interrupted by atropine.

W. D. H.

The Behaviour of Morphine in the Frog. BRONISLAW FRENKEL (*Arch. exp. Path. Pharm.*, 1910, 63, 331—340).—Most previous workers on morphine have employed warm-blooded animals. Frogs differ from these in the prolonged period of primary excitation, culminating in tetanus, and in manifesting no immunity. Morphine is retained for a long time in the frog's body; after eight days it is, however, all eliminated, mainly by the alimentary tract, from which 65% of the amount given is recoverable; comparatively little (10%) is destroyed in the body. None is found in the central nervous system, but the liver, and next to that the muscles, contain most. The destruction is increased by an elevation of body-temperature and of oxygen tension.

W. D. H.

Influence of the Concentration of Hydroxyl Ions in a Sodium Chloride Solution on the Relative Anti-Toxic Action of Potassium and Calcium. JACQUES LOEB (*Biochem. Zeitsch.*, 1910, 28, 176—180).—The poisonous action of sodium chloride on the developing fertilised eggs of the sea-urchin is neutralised to a greater extent by potassium than by calcium in neutral or slightly acid solution; in alkaline solution, on the other hand, calcium is more effective than potassium. In all cases the effect of a mixture of potassium and calcium is greater than the sum of the separate effects. Addition of alkali to a mixture of potassium and sodium chloride increases the poisonous action, whereas alkali renders a mixture of sodium and calcium chloride less poisonous.

G. S.

Why Does Sodium Cyanide Diminish the Poisonous Action of Sodium Chloride on Sea-Urchin's Eggs? JACQUES LOEB and HARDOLPH WASTENEYS (*Biochem. Zeitsch.*, 1910, 28, 340—349).—Warburg (this vol., ii, 628) accounts for the poisonous action of sodium chloride on sea-urchin's eggs on the assumption that it increases the oxidation processes to such an extent that the egg is disadvantageously affected, the favouring effect of the calcium being due to its property of bringing back the rate of oxidation to the normal value. The authors have determined the amount of oxygen used up when the eggs develop in different solutions, and show that in sodium chloride solution there is no increase, but if anything a decrease, in the amount of oxygen absorbed. Warburg's observation that more oxygen is used up in a given time in a solution containing sodium chloride and cyanide than in the same solution with the addition of calcium, is confirmed, but no final explanation is advanced. The anti-toxic effect of sodium cyanide in a solution containing sodium chloride is ascribed to the former substance retarding the development of the egg or the oxidation changes accompanying development. G. S.

The Inhibition of the Toxic Action of Certain Poisons on the Eggs of Sea-Urchins Due to Depression of Oxidation in the Eggs. JACQUES LOEB (*Biochem. Zeitsch.*, 1910, 29, 80—95).—It was found that the stoppage of oxidation in the eggs, either by sodium cyanide or by driving out oxygen from the artificial sea-water by hydrogen, inhibited the toxic action of the following classes of substances: (1) Neutral salt solutions; (2) sugar solutions; (3) hyper- and hypo-tonic solutions; (4) narcotics (chloral hydrate, phenylurethane, chloroform, and alcohol). This action of deficient oxidation cannot be due to inhibition of the bifurcation process, for it inhibits the toxic action of substances like chloral hydrate, which themselves inhibit the bifurcation of the egg. S. B. S.

The Removal of the Poisonous Effects of Hydrocyanic Acid by Substances which Split off Sulphur. JOSEF HEARING (*Biochem. Zeitsch.*, 1910, 28, 208—212).—Lang found that hydrocyanic acid compounds led to the excretion of thiocyanates, and in minced organs the change of potassium cyanide into thiocyanate also occurs, the sulphur arising probably from the cystine of protein. He further showed that various sulphur compounds protect the organism against the poisonous effects of hydrocyanic acid. Reid Hunt and others have confirmed this. In the present research on rabbits, the antidotes investigated were sodium tetrathionate, cystine, β -thiolactic acid, and α - and β -dithiodilactic acids, and Lovén's trithio-compound, $C_6H_{10}O_4S_3$. All were protective in some degree, but none reach thiosulphate in efficiency. W. D. H.

The Supposed Immunity of Toads to their own Poison (Secretion of Skin Glands). HERMANN FÜHNER (*Arch. exp. Path. Pharm.*, 1910, 63, 374—385).—It has been generally stated that toads, like snakes, are immune to their own poison. The cutaneous secretion

of toads contains several active constituents, namely, a hæmolysin called phrynolysin, and two substances, bufonin, similar to cholesterol, and an easily soluble substance, bufotalin. The last two substances produce the main toxic symptom, namely, a digitalis-like action on the heart. It is shown in the present research that the hearts of frogs are easily affected by the toad's poison, stoppage and systolic contracture being produced; the same occurs also in the toad's heart. This action is to a great extent annulled by previous treatment of the secretion with cholesterol.

W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

Spontaneous Ignition of Coal. ERNST GALLE (*Centr. Bakt. Par.*, 1910, ii, 23, 461—473).—The bacteriological examination of five kinds of coal showed the presence of seven kinds of spores, of which three were identified as *Bacillus subtilis*, *B. mesentericus*, and a kind of *Narcina*. The spores develop at the ordinary temperature and without air, and non-sterilised coal, moistened with tap-water, gave in one experiment a luxuriant growth of bacteria.

Further experiments on the production of gas from coal by the action of bacteria showed that four of the seven microbes produce inflammable gas, about three-fourths methane, about one-fifth carbon dioxide, with small amounts of carbon monoxide. The bacterial action was found to result in a rise of temperature, the greatest effect being produced by *B. pseudosubtilis* (1.3°). Finally, it is shown that coal which has been subjected to the action of the bacteria ignites at a lower temperature.

The conclusion is drawn that whilst bacteria are not the direct cause of the spontaneous ignition of coal, they may play an important part in the production of conditions which result in ignition.

N. H. J. M.

The Destruction of Gelatin by Micrococcus prodigiosus. P. MESEHNITZKY (*Biochem. Zeitsch.*, 1910, 29, 101—125).—*Micrococcus prodigiosus* contains an enzyme which is capable of liquefying gelatin, and can be detected in culture media after some days. It is very heat-stable. The products of the action of the organism on gelatin were also investigated, and the amounts of nitrogenous matter precipitable by tannin solutions after varying intervals of culture were estimated. In addition to these peptides, crystalline substances were also produced, of which only glycine was identified with certainty. Probably leucine and proline were also produced.

S. B. S.

Action of Nitrates in Alcoholic Fermentation. AUGUSTE ERSBACH and A. LANZENBERG (*Compt. rend.*, 1910, 151, 726—729).—It has been held that the presence of nitrates during alcoholic ferment-

tation is harmful, owing to the toxicity of these substances towards yeast. This view, based on the experiments of Mayer (1869) and of Dubrunfaut (*Compt. rend.*, 1871, 73, 263), is now shown to be incorrect. Potassium nitrate has a slightly inhibitory effect when present to the extent of 0.1%, but in concentrations exceeding this, up to 2%, it strongly stimulates the production of alcohol.

Experiments were also conducted on zymase with similar results; the amount of carbon dioxide produced was found to increase to a marked extent when the salt was present in 0.5—4% solution. The optimum concentration varied with the nature of the yeast from which the enzyme was prepared. It was found, however, that the multiplication of yeast cells is checked by nitrates, especially in the more concentrated solutions.

W. O. W.

Influence of Nitrates on Alcoholic Ferments. E. KATSER (*Compt. rend.*, 1910, 151, 816—817. Compare Abstr., 1907, ii, 268, 383, 903; Fernbach and Lanzenberg, preceding abstract).—Manganese nitrate is even more active than the alkali nitrates in promoting alcoholic fermentation. The optimum dose of this salt varies with the nature of the yeast.

W. O. W.

Influence of Environment on Enzymic Action. FREDERICK W. PAVY and HUBERT W. BYWATERS (*J. Physiol.*, 1910, 41, 168—193).—The inverting power of an aqueous extract of yeast is increased ten to fifteen-fold by the addition of a boiled extract of yeast. This is attributed to the acidity of the boiled extract, for the same results can be obtained by substituting acetic acid for the boiled extract. If yeast cells are used, acetic acid has the same activating effect up to a certain optimum point, after which addition of acid diminishes the inverting power. After desiccation, treatment with alcohol, or grinding with kieselguhr, yeast yields an aqueous extract with enhanced enzymic power, which acid fails almost entirely to increase further. The activity produced by acid can be removed by the addition of alkali. The diastatic enzyme of the oyster is influenced by boiled oyster extract and by acetic acid in the same way, but not to so great an extent. The addition of acid, not only increases the amount of reducing substance, but also increases its reducing power. The post-mortem production of sugar in the liver can be checked by an alkaline injection, and subsequently the production of sugar can be increased by rising amounts of acid until an optimum is reached. The dried or coagulated liver behaves to acid and alkali like the fresh organ. The post-mortem production of sugar and of acid by the liver runs on parallel lines, and the acidity so produced is regarded as the governing factor for sugar formation. Fluorides restrain the formation of both acid and sugar.

W. D. H.

The Kinetics of Toxic Action of Dissolved Substances. I. The Influence of Concentration. THEODOR PAUL, GUSTAV BIRNSTEIN, and ANTON REUSS (*Biochem. Zeitsch.*, 1910, 29, 202—248).—The disinfecting action, determined by means of the Krönig-Paul garnet method, of various acids on different bacteria was estimated. Acetic

and *n*-butyric acids were found to be more powerful disinfectants than hydrochloric acid in isohydric solutions. The disinfection constant of hydrochloric acid in $N/25$ — $N/150$ solutions was found to be approximately proportional to the square-root of the concentration of the acid. For butyric acid in concentrations $N/6.6$ — $N/26$, it was proportional to the square of the concentration, or for acetic acid in concentrations $N/2$ — $N/31$, the disinfection rate was approximately proportional to the concentration itself. The relationship between the disinfecting action and concentration of a substance can be expressed by the general equation: $K = A.C^B$, where K = constant of disinfection rate, C = concentration, and A and B are constants. The exponent B is the characteristic constant for any particular disinfectant. S. B. S.

The Kinetics of Toxic Action of Dissolved Substances. II. The Influence of Neutral Salts and Temperature on the Disinfection Rate of Acids. THEODOR PAUL, GUSTAV BIRSTEIN, and ANTON REUSS (*Biochem. Zeitsch.*, 1910, 29, 249—278).—Certain inorganic substances increase the disinfection rate of inorganic acids without themselves acting as disinfectants; an aqueous solution with equivalent quantities of the acid HX , and the salt MX , has approximately the same disinfection rate as an acid HX . The disinfection rates of acid-salt mixtures with different contents in salt are approximately the same as those of the salts having the corresponding concentration. The temperature-coefficients of the disinfection rates were also determined. S. B. S.

Catalase of Moulds. ARTHUR W. DOX (*J. Amer. Chem. Soc.*, 1910, 32, 1357—1361).—A study of various species of *Penicillium* and *Aspergillus* has shown that these moulds contain catalase. When the mycelium first appears on the surface of the culture-medium, it contains a very active catalase, but, after about fifteen days, the quantity of this enzyme in the cells of the fungus gradually decreases, whilst that in the medium steadily increases. The means by which this passage of the catalase from the mould into the medium is effected cannot at present be explained, but it seems probable that some of the cells of the fungus undergo disintegration or suffer a loss of vitality, thus allowing the enzyme to diffuse or to be mechanically discharged into the medium. E. G.

Formation of Hydrogen Cyanide in the Germination of Seeds. CIRO RAVENNA and M. ZAMORANI (*Atti R. Accad. Lincei*, 1910, [v], 19, ii, 356—361).—Although the seeds of *Sorghum vulgare* do not contain hydrogen cyanide, yet the distillate from them when germinating always yields that substance. This is the case whether germination takes place in the dark or in light, and the amount found increases to a certain limit (0.08% of the weight of the seeds), then decreases. The seeds of *Linum usitatissimum*, which contain hydrogen cyanide (0.027%), behave similarly, but the maximum amount is greater (0.5%). It is suggested that carbon dioxide or carbohydrates are concerned in the formation of the acid. Less was produced (in some experiments) in the absence of carbon dioxide,

whilst seedlings grown in the dark and supplied with dextrose produced more than similar etiolated plants not so treated.

R. V. S.

The Elective Rôle of the Root in the Absorption of Salts. JEAN DE RUFZ DE LAVISON (*Compt. rend.*, 1910, 151, 675—677).—The rate of absorption of sodium, potassium, and calcium chloride from aqueous solutions by the cut stems and roots of plants has been determined. It was found in the case of the haricot that sodium chloride was not absorbed by the roots, whilst considerable quantities passed into the stem. The latter absorbed all the salts presented to it with equal facility, whilst the roots showed a marked selective action.

W. O. W.

Cryoscopic Determination of the Osmotic Pressures of Some Plant Organs. W. R. GELSTON ATKINS (*Sci. Proc. Roy. Dubl. Soc.*, 1910, 12, 463—469).—Records are given of measurements of the osmotic pressure of the juices extracted from over fifty fruits, leaves, stems, etc., of plants. In the case of fruits the pressures varied from 5.94 atm. for a specimen of *Lycopersicon esculentum* to 28.27 to 29.53 atm. for *Prunus communis*, the high numbers in the latter case being due probably to the sugars. *Citrus Limonum* gives larger variations, 10.46 to 12.21 atm. for samples obtained in August, and 12.05 to 14.06 atm. for those obtained in February. The pressure in the rind is somewhat lower. The red stems of *Rheum officinale* gave 6.52 atm., this low number being associated with the relatively low molecular weight of oxalic acid, the chief constituent of the juice.

The pressure in the underground organs studied ranged from 6.5 atm. in the tubers of *Solanum tuberosum* to 18.7 atm. in the tubers of *Helianthus tuberosus*.

Calculations of the mean molecular weight showed that the red stem of *Rheum officinale* gave the lowest value, 76, and the tubers of *Helianthus tuberosus* the highest value, 394. The fruits gave values varying from 110 to 231.

The author concludes that similar plant organs of the same species have approximately equal osmotic pressures, but this deduction does not apply to leaves.

E. J. R.

Hydrocarbons of Vegetable Origin. TIMOTHÉE KLOBB, JULES GARNIER, and R. EHRWEIN (*Bull. Soc. chim.*, 1910, [iv], 7, 940—950). Compare Klobb and Fandre, *Abstr.*, 1907, ii, 123).—Methods for the isolation of hydrocarbons occurring in plants are described, and a number of the hydrocarbons are characterised. Many similar saturated hydrocarbons of vegetable origin have been described by Power and his collaborators.

The plant material, usually flowers, is extracted with either cold or warm light petroleum, and the soft extract left on removal of most of the solvent is dissolved as far as possible in boiling acetone. From the filtered hot acetone solution the hydrocarbon separates on cooling, and may be purified if necessary by boiling with potassium hydroxide

in alcohol and subsequent recrystallisation from ether or acetone. An alternative process consists in treating a concentrated alcoholic extract of the flowers with aqueous ammonia solution (15–20%) for several days to remove tannins, etc., and then extracting with ether. The residue left on distilling off the ether is treated with potassium hydroxide in alcohol, the solvent distilled off, and the residue poured into water and extracted with ether. The residue from the last solvent is extracted with boiling alcohol, which, on cooling, deposits the hydrocarbon in crystalline form. These hydrocarbons dissolve in warm light petroleum, chloroform, or carbon disulphide, and can be obtained in microscopic crystals from boiling acetone or alcohol, but they assume a more definitely crystalline form if left in contact with acetone during one or two days, or if obtained by slow evaporation from dilute solutions in ether. The melting point varies from 53° to 65° (Maqacune block). They are unaffected by bromine or potassium permanganate.

The flowers of *Arnica montana* yield, in addition to arnidiol (Abstr., 1904, i, 410; 1905, i, 594), a mixture of hydrocarbons, from which one having the formula $C_{30}H_{62}$, m. p. 62°, has been isolated in a pure state (compare Börner, *Inaug. Diss.*, Erlangen, 1892). *Matricaria chamomilla* flowers, treated by the second general process, furnish a hydrocarbon, $C_{29}H_{60}$, m. p. 52–54°, which crystallises in colourless lamellae. The hydrocarbon, $C_{25}H_{50}$, from *Antennaria dioica*, m. p. 64–66°, crystallises in nacreous lamellae from acetone. Worm seeds (flowers of *Artemisia maritima*) yield a hydrocarbon, $C_{32}H_{66}$, m. p. 55–58°, which crystallises in colourless lamellae, and even after purification evolves hydrogen bromide with bromine in carbon tetrachloride. The hydrocarbon, $C_{27}H_{56}$, from *Fussilago fufura* flowers, m. p. 57–59°, forms nacreous, hexagonal lamellae. The flowers of *Tilia europaea* yield a hydrocarbon, $C_{28}H_{58}$, m. p. 54–56°. The hydrocarbon isolated by Naudin from chamomile flowers (Abstr., 1884, 391) is shown to have the formula $C_{30}H_{62}$; it melts at 64°, and crystallises slowly from ether in colourless lamellae.

The formulae assigned to the various hydrocarbons have been controlled in most cases by cryoscopic determinations in naphthalene.

T. A. II.

Formation and Distribution of Certain Alkaloids in *Papaver somniferum*. M. KERDOSCH (*Pharm. Weekblad*, 1910, 47, 1062–1074, 1081–1094, 1106–1119).—An investigation of the formation and distribution of the alkaloids of *Papaver somniferum* in the different parts of the plant at various stages of its growth. The seed contains a trace of narcotine and amorphous alkaloids. After three days' germination, the seeds have developed an appreciable quantity of narcotine, and the alkaloids make their appearance in the plant in the order: narcotine, codeine, morphine, papaverine, narcaine, and thebaine. When the plants are 5–7 cm. high they contain the four alkaloids first named, and they are present in all the organs of the plant from the time of flowering until it reaches maturity, when all the organs contain narcotine, codeine, and morphine. The composition of the sap differs in different parts of the plant. Germina-

tion of the seeds in an atmosphere free from nitrogen also produces narcotine, its formation being occasioned by the decomposition of proteins. The proportion of narcotine in the buds is much greater than in the unripe seed husks.

With a solution of cadmium iodide (1.8 gram) and caesium iodide (5 gram) in 100 c.c. of water, papaverine, codeine and morphine yield additive products readily identified by their crystalline form. On addition of the reagent, each of the six alkaloids gives an amorphous precipitate; on warming, the additive products of those named dissolve, and crystallise on cooling, whilst those of the others remain amorphous.

A. J. W.

Chemical Examination of the Bark of a Species of *Prunus*. HORACE FINNEMORE (*Pharm. Journ.*, 1910, [iv], 31, 604—607).—A spurious substitute for *Prunus serotina* bark, which is very similar to the bark of *P. emarginata*, has been examined and found to differ from the true bark in containing no cyanogenetic glucoside yielding benzaldehyde on hydrolysis (Power and Moore, *Trans.*, 1909, 95, 243). It contains quercimeritrin (Perkin, *Trans.*, 1909, 95, 2181), a new colouring matter glucoside (prunitrin), and a phytosterol as its principal constituents.

A concentrated alcoholic extract of the bark was dissolved in water and extracted with ether, which caused the precipitation of some impure prunetin (see below), but dissolved a mixture of (1) an acid substance, m. p. 121° , crystallising in plates, and giving a reddish-purple coloration with ferric chloride solution; (2) a phytosterol, m. p. 137° , which furnished an acetyl derivative, $C_{27}H_{43}OAc$, m. p. 121° , crystallising in lustrous plates; (3) fatty matter furnishing the same phytosterol and formic, butyric, and palmitic acids on hydrolysis; (4) prunetin, $C_{16}H_{12}O_5$, m. p. 242° (corr.), which crystallises in colourless needles, dissolves in alkalis with a yellow colour, but is sparingly soluble in organic solvents. It furnishes a monoacetyl derivative, m. p. 190° , a diacetyl derivative, m. p. $221-226^{\circ}$ (corr.), and a dibenzoyl derivative, m. p. 215° , all of which crystallise well. On treatment with methyl iodide and sodium methoxide it yields a monomethyl ether, m. p. 145° , crystallising in flat, lustrous needles, and this in turn gives a monoacetyl derivative, m. p. 202° , crystallising in colourless prisms. When heated with hydriodic acid, prunetin furnishes 1 mol. of methyl iodide, and prunetol,

m. p. 290° , which crystallises in colourless needles, yields a triacetyl derivative, m. p. 205° , and on methylation furnishes a mixture of prunetin methyl ether (see above), and a second product, which is insoluble in ether and furnishes a crystalline acetyl derivative, m. p. 186° . Both prunetin and prunetol, on solution in boiling acetic acid and addition of sulphuric acid, furnish unstable sulphates of the type described by Perkin and Pate (*Trans.*, 1895, 67, 644). On fusion with potassium hydroxide, prunetin yields *p*-hydroxyphenylacetic acid and a substance which gives the reactions of phloroglucinol, and furnishes methyl iodide on treatment with hydriodic acid. It is considered that

prunetin is closely related to scutellarein (Molisch and Goldschmiedt, Abstr., 1902, i, 48) in constitution, and may have the formula

The aqueous solution, after extraction with ether, deposited on standing crystals of quercimeritrin (Perkin, Trans., 1909, 95, 2181).

The aqueous extract on defaecation with lead acetate and subsequent extraction with ethyl acetate furnished a new glucoside, *prunitrin*, $\text{C}_{20}\text{H}_{24}\text{O}_{11}$, crystallising from hot water in slender needles. This, on hydrolysis with hydrochloric acid, yielded prunetin and dextrose, and is probably the source of prunetin in the bark. Yellow colouring matters also occur in *Prunus cerasus* and *P. avium* barks.

T. A. H.

The Resistibility of Wheat and Barley to Poisons and its Importance for Sterilisation. HEINRICH SCHROEDER (*Centr. Bakt. Par.*, 1910, ii, 28, 492—505).—The following method was found to be suitable for sterilising wheat and barley grains. The seeds are first well washed in running water, and then immersed in 5% silver nitrate solution for eighteen to twenty-four hours. They are then washed with water, and allowed to swell in a dilute solution of sodium chloride.

The method would presumably be suitable for other seeds, such as rice and oats, which are protected similarly to wheat, but it does not seem suitable for sterilising leguminous seeds.

Only undamaged seeds can be sterilised with silver nitrate.

N. H. J. M.

Influence of Some Artificial Oxydases and of Some Metallic Compounds on the Growth of Wheat. V. NASARI (*Atti R. Acad. Lincei*, 1910, [v], 19, ii, 361—367).—From experiments on the germination of wheat in the laboratory and also its growth under agricultural conditions, the authors find that compounds of manganese (dioxide, sulphate, carbonate) exert a favourable influence on the result obtained. The manganese compounds were supplied to the plant in three ways: (1) as a component of an artificial oxydase, with which the seeds were enveloped; (2) as a component of a paste containing starch and nitrogenous organic matter, with which the seeds were covered; (3) as a fertiliser. Ferric oxide may also have a beneficial effect, but ferrous sulphate only prevents mildew. Copper and aluminium sulphates affected growth unfavourably.

R. V. S.

Putrefaction Bases from the Decomposition of Soy Beans (*Glycine hispida*). KIYOHISA YOSHIMURA (*Biochem. Zeitsch.*, 1910, 28, 16—22. Compare Abstr., 1909, ii, 928).—The following bases can be isolated from the products formed when soy beans are boiled with water, the moist beans rubbed in a mortar until the whole has a pasty consistency, and left for some four months at the ordinary temperature: β -amino-4-ethylglyoxaline (β -iminoazolyethylamine: Ackermann, this vol., i, 419), 0.18; tetramethylenediamine, 0.25;

pentamethylenediamine, 0.53; trimethylamine, 0.23; ammonia, 4.69. The numbers refer to grams per kilo. of air-dried material.

Histidine, arginine, and lysine could not be detected. J. J. S.

Harmlessness of Sulphurous Acid in Wines. P. CARLES (*Ann. Chim. anal.*, 1910, 15, 419—421; *Bull. Soc. chim.*, 1910, [iv], 7, 998—1001).—The author emphasises the non-injurious effects of sulphurous acid, points out the necessity of using this acid in the manufacture of certain classes of wines, and draws attention to a report recently issued (this vol., ii, 734) which deals with this subject. W. P. S.

Importance of Osmotic Pressure and of Electrolytic Conductivity in Judging Soils. JOSEF KÖNIG, JULIUS HASENBAUMER, and H. MEYERING (*Landw. Versuchs-Stat.*, 1910, 74, 1—56).—The estimation of the osmotic power of taking up water yields good results when a constant temperature (18—20°) is maintained. The process can also be employed for the estimation of the mol.-wt. of substances not, or only slightly, subject to diosmosis.

Estimation of electrolytic conductivity of soils generally yields values closely related to the osmotic power of taking up water. Both are considerably increased by the usual manures, and diminished by the growth of plants, so that both give expression to the degree of solubility of plant nutrients in the soil. Electrolytic conductivity is more readily estimated than the osmotic taking up of water; the latter seems, however, to furnish the more trustworthy results.

As electrolytic conductivity increases as the size of soil particles diminishes, a constant degree of fineness, not exceeding 1 mm., should be employed.

The potassium and phosphoric acid of dipotassium phosphate are completely absorbed up to a certain point; sulphates are partly absorbed, whilst nitrates and chlorides are not absorbed at all.

Increased yields are obtained by treating exhausted soils containing complex humates or humus colloids with hydrogen peroxide.

Growth of clover resulted in increased amounts of soluble nutrients in the soil. N. H. J. M.

The Ammonia in Soils. EDWARD J. RUSSELL (*J. Agric. Sci.*, 1910, 3, 233—245).—Soil contains a number of nitrogenous compounds that readily evolve ammonia on treatment with alkalis. In order to discriminate between these and the true ammonium compounds present, the author investigated the relationship between the concentration of alkali and evolution of ammonia when soil was distilled with alkalis under diminished pressure. The resulting curves show that two stages exist; in the first, the ammonium compounds are decomposed; in the second, other nitrogen compounds break down. The two stages are very marked when either magnesium oxide or alcoholic potash is used as the alkali, and therefore the author uses either of these in determining the ammonia free or combined in soils.

A number of determinations show that ammonia is present only in minute amounts in normal soils, although when nitrification was

stopped, marked accumulations occurred. It follows that the rate of nitrification must be greater than that of ammonia production, and in normal conditions is limited by this rate. In the light of this observation, it is shown that the various methods in vogue for studying the rate of nitrification in soil really deal with three separate things: the rate of ammonia production in soils, the rate of nitrate production in soils, and the rate of nitrification in a culture solution; the discordance of the results is therefore explained.

When ammonium salts are added to soil a certain proportion enters into a stable combination that is not decomposed on distillation with alcoholic potash or magnesia, and is therefore not an ammonium compound. Its constitution, however, has not been determined.

E. J. R.

Biochemical Resolution of Phosphoric Acid in Soils. RENATO PEROTTI (*Biol. Zentr.*, 1910, 39, 717—718; from *Staz. sper. agrar. ital.*, 1909, 42, 537—538).—The solution of phosphoric acid in ordinary soils depends on the action of acids producing bacteria, and is increased by the presence of carbohydrates, especially disaccharides, and of ammonium sulphate. Ammonium tartrate is indifferent, whilst ammonium nitrate gives sometimes positive and sometimes negative results. Calcium and magnesium carbonates retard the action of the bacteria, whilst alumina is more indifferent, and ferric oxide is somewhat favourable.

N. H. J. M.

Suitability of the Calcium of Calcium Silicate for the Nutrition of Plants. HANS MIETH (*Landw. Versuchs-Stat.*, 1910, 74, 81—120).—Calcium in the form of silicates is readily utilised by plants, and far more silica is taken up than calcium. The silicates are decomposed by plants with production of free silicic acid and calcium carbonate.

In estimating the available calcium in soils, it is necessary to include silicates as well as carbonate.

N. H. J. M.

Analytical Chemistry.

New Normal Solution and Reagent Bottle. FRANK M. DAVIS (*J. Amer. Chem. Soc.*, 1910, 32, 1277—1279).—The normal solution bottle described consists of a long, narrow bottle provided with a ground glass cap, furnished with a groove to admit air when desired. The bottle has two side-tubes, one near the top, and the other near the bottom. To these is fused a wider tube, graduated like a burette, and having a delivery tube at the lower end. This delivery tube is provided with a glass stopcock, and another stopcock is placed in the lower of the two tubes connecting the burette with the bottle.

The apparatus is supported in a light wooden frame suspended by trunnions between two triangular racks.

On opening the stopcock between the burette and bottle, adjusting the cap of the bottle so that air can enter, and tilting the apparatus forward if needful, the solution flows from the bottle into the burette. The stopcock is then closed, and the bottle replaced in an upright position. The liquid can now be drawn off from the burette as required.

The reagent bottle is of similar construction, but the burette is set into the wall of the bottle, so that the apparatus can be held in the hand, and a support is not necessary.

The advantages of these forms of apparatus are that measured quantities of the reagent can be withdrawn from the bottle without recourse to measuring cylinders or pipettes, and that the risk of extraneous matter being admitted into the reagent is obviated.

E. G.

A Very Sensitive Indicator. JULIUS F. SACHS (*Chem. Zeit.*, 1910, 34, 1192).—Radish skins are extracted for a few hours with their own weight of 96% alcohol, and should the liquid show any acidity to litmus paper, it is carefully neutralised with $N/100$ potassium hydroxide. This solution, 2 c.c. of which are added to 50 c.c. of the liquid to be tested, makes an excellent indicator for both acid and alkalis, turning intensely red with the former, and green with the latter. It is more delicate than methyl-orange or phenolphthalein, but, like the latter, it is affected by carbon dioxide.

L. DE K.

Rupp and Loose's Indicator. IWAN I. VON OSTROMISLZENSKY and I. S. BABADSCIAN (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 609–611. Compare Abstr., 1908, ii, 90).—Rupp and Loose's methyl-red is a very delicate indicator for alkali hydroxides, but the authors were unable to isolate it by the method described by Rupp and Loose. By employing the theoretical quantity of dimethylaniline, extracting the products of reaction with ether or chloroform, and evaporating the latter, the substance was isolated, but it could not be purified by recrystallisation.

Z. K.

A Delicate Reaction for Hydrogen. CONSTANTIN ZENGELS (*Zeitsch. anal. Chem.*, 1910, 49, 729–732).—The process is based on the fact that platinum and palladium absorb hydrogen, and then exercise a reducing action when heated with molybdenum solution. This is made by dissolving 1 gram of molybdenum trioxide in dilute sodium hydroxide, acidifying the liquid with hydrochloric acid, and diluting to 200 c.c.

The gas to be tested is first passed through a wash-bottle containing aqueous sodium hydroxide. The end of the delivery tube dipping into a test-tube containing a few c.c. of the reagent is tied over with platinum gauze, and if hydrogen is present in not too minute a quantity, the solution will turn blue.

A still more delicate test is to allow the gas to come in contact with spongy palladium heated at 80–120° in an atmosphere of carbon dioxide. A convenient apparatus is described for this purpose. The

palladium is then warmed with molybdenum solution to see if there is any reduction.

L. DE K.

Electrolytic Estimation of Chlorine in Hydrochloric Acid with the Use of a Silver Anode and a Mercury Cathode. JACOB S. GOLDBAUM and EDGAR F. SMITH (*J. Amer. Chem. Soc.*, 1910, 32, 1468—1471).—As a result of criticism of the electrolytic method (*Abstr.*, 1907, ii, 574, 988; 1908, ii, 1072) for the estimation of chlorine when applied to solutions containing free hydrochloric acid, the authors have made further experiments. It is shown that satisfactory results can be obtained if certain precautions are taken. Silver is deposited on the platinum gauze anode by electrolysis of a cyanide solution, and the electrode is then dipped in dilute hydrochloric acid, washed thoroughly with distilled water, and ignited to incipient redness in a Bunsen flame. By this means any admixed cyanide is completely removed.

To obviate the disturbing effect of the formation of oxide on the anode, the latter is placed for ten to fifteen minutes in an electric oven heated to 300°, when the silver oxide is completely decomposed.

Experimental data are recorded which show that the estimation of chlorine in hydrochloric acid can be effected without appreciable error if the above precautions are observed. Similar data are given for the electrolytic estimation of bromine and hydrobromic acid, but the results appear to be rather low.

H. M. D.

Catalytic Action of Silver Salts [on Chlorates in Presence of Aniline Hydrochloride]. JUAN PAGES VIRGILI (*Anal. Fis. Quim.*, 1910, 8, 222—226).—Traces of silver very much intensify the colour produced by the action of a chlorate on the solution of aniline hydrochloride employed in the author's method of estimating chlorates colorimetrically (*Abstr.*, 1909, ii, 179). It is therefore necessary if silver nitrate has been used as a means of removing other substances present (for example, ferri-cyanides) to ensure that any excess of silver is eliminated by the addition of sodium chloride before proceeding to estimate chlorates. The manner in which the silver acts is uncertain, but possibly it exerts a catalytic action, by which the velocity of the change producing the coloration is accelerated. The sensitiveness of the method formerly described can be much increased by adding one or two drops of a 1% solution of silver nitrate before adding the aniline reagent; in presence of silver, traces of chlorate, which ordinarily cannot be detected or estimated, give a distinct coloration. Thus 2 grams of sodium nitrate containing 0.00005 gram of chlorate usually gives a coloration only after several minutes; in presence of silver, 0.2 gram of the nitrate produces far more coloration after a few seconds. This simplifies the examination of refined nitrates containing less than 0.0001 gram of chlorate.

Traces of copper and of chloroplatinic acid exercise a similar action to silver in increasing the colour, but, unlike silver, they appear to retard its production.

W. A. D.

Weselszky's Method for Estimating Bromine and Iodine. JOSÉ CASARES GIL (*Anal. Fis. Quim.*, 1910, 8, 33—40).—Tests made

of the accuracy of Weszelszky's method (Abstr., 1900, ii, 436, f.), estimating the amount of iodine in known weights of dissolved iodide showed that heavy loss of iodine occurs if attempts are made to remove by direct evaporation the excess of chlorine used in oxidising the iodide to iodate. If, however, the excess of chlorine is eliminated by aspirating a rapid current of air through the hot acid solution, accurate results are obtained.

Contrary to Weszelszky's statement, potassium chlorate liberates traces of iodine from potassium iodine in presence of hydrochloric acid under the conditions used in the method; on adding 0.029 gram of potassium chlorate dissolved in 125 c.c. of distilled water to 5 c.c. of 10% potassium iodide and 5 c.c. of hydrochloric acid, 3 drops of $N/10$ sodium thiosulphate are required to destroy the iodine, using starch as indicator in the usual way. If the chlorate is dissolved in only 15 c.c. of water, 5 drops of $N/10$ thiosulphate are required. To convert the sodium hypochlorite formed during the oxidation of bromides in Weszelszky's method by chlorine in alkaline solution entirely into chlorate, it is absolutely necessary to evaporate to dryness and heat the residue for some time on the water-bath. Control analyses made with pure potassium bromide show that Weszelszky's method gives fairly accurate results.

W. A. D.

Precipitation of Sulphate Ions as Barium Sulphate. EXSR RUPPIN (*Chem. Zeit.*, 1910, 34, 1201).—The following method is recommended. The solution (250 c.c., furnishing about 1.5 grams of barium sulphate) is slightly acidified with hydrochloric acid and heated to boiling. Boiling solution of barium chloride (200 grams per litre) is then added all at once in excess of about 50%, and the whole set aside until the following day. The mother liquor is decanted through a filter, and the precipitate digested with 125 c.c. of very dilute nitric acid during fifteen minutes, the clear liquid being decanted through the same filter, and the filtrate and washings collected and concentrated to 200 c.c. To this, 2 c.c. of saturated barium nitrate solution are added, and after thirty minutes the precipitate is filtered off and washed. The main precipitate is then collected on a filter and dried at 100°. The two filter papers are burnt and their ash added to the precipitate, and the whole ignited and weighed with the usual precautions.

A less accurate, but quicker, method consists in precipitating the sulphate by the use of a 20% solution of barium chloride in an excess of about 33%, filtering after about thirty minutes, washing the precipitate with about 100 c.c. of boiling water by decantation, and continuing the washing on the filter paper until the wash-water is free from chlorides.

T. A. H.

Estimation of Organic Matters in Spent Sulphuric Acids. RUD. MICHEL (*Chem. Zeit.*, 1910, 34, 1210—1211).—The apparatus consists of a round-bottomed flask fitted with a stopcock funnel, and connected by means of a bent capillary tube to the three-way tap of an ordinary gas burette filled with water. Into the flask are introduced 20 c.c. of a saturated solution of potassium permanganate, and into

the funnel is placed a known volume of the acid to be tested. The tap at the lower end of the burette being opened, the acid is admitted slowly into the flask, when carbon dioxide is evolved and enters the burette. The remaining gas is expelled from the flask by introducing water through the funnel until the liquid reaches the three-way tap. The burette is now closed, and the volume of gas read off with the usual precautions. The exact volume of carbon dioxide is then found by absorption with aqueous potassium hydroxide in the usual manner.

The carbon dioxide is calculated to its weight of carbon; 75 parts of the latter average 100 parts of (resinous) organic matter.

L. DE K.

Use of Nitron in the Analysis of Nitrates. ALEXIS M. VASILIEFF (*J. Russ. Phys. Chem. Soc.*, 1910, 42, 567—570. Compare Gutbier, Abstr., 1905, ii, 418).—A somewhat modified form of Busch's gravimetric estimation of nitric acid in nitrates by means of nitron.

The weighed substance is dissolved in 100 c.c. of water and boiled, after which 10—12 drops of dilute sulphuric acid are added for every 0.1 gram of NO_3 , and 10 c.c. of a 10% solution of nitron in 5% acetic acid. After cooling, the beaker is surrounded by ice for five to eight hours, at the end of which time the solution is filtered through a Gooch crucible containing Swedish filter paper instead of asbestos. The precipitate is washed five to seven times with 3—5 c.c. of a saturated solution of nitron nitrate cooled to 0° , and finally once with 3—5 c.c. of water at 0° . It was then dried at 105° — 110° . The method gives good results, and is evidently independent of the nature of the metal.

Z. K.

Detection and Estimation of Arsenic Acid in Presence of Arsenious Acid by means of Magnesia Mixture. JOHANNES C. BRUNNICH and F. SMITH (*Zeitsch. anorg. Chem.*, 1910, 68, 292—296).—The experiments of Lutz and Swinne (Abstr., 1909, ii, 1052) have been repeated, using weaker arsenite solutions, such as are employed for agricultural analyses. The best results are obtained by using a magnesia mixture containing 5.5% magnesium chloride, 10.5% ammonium chloride, and only 1.4% ammonia. With such a solution a distinct crystalline precipitate is obtained in ten minutes from a solution containing only 0.0002 gram As_2O_3 , alone or in the presence of 0.025 gram As_2O_3 . The addition of ammonia, although generally recommended, is disadvantageous.

The separation is quantitative if the quantity of arsenite present does not much exceed 0.5% As_2O_3 . The quantity of alkali salts present should not exceed an original content corresponding with 1% NaOH . Citrates completely prevent the precipitation of arsenates.

C. H. D.

Apparatus for the Estimation of Carbon, Arsenic, and Sulphur in Iron and Steel. GEORG PREUSS (*Zeitsch. angew. Chem.*, 1910, 23, 1980—1981).—The apparatus is essentially the same as that described and figured previously (this vol., ii, 893). It consists of

employed. Further work on this subject has now been carried out. The alkaline-earth metals were used, and the acetate, formate, and lactate electrolytes described by Davison (*Abstr.*, 1905, ii, 854). Corresponding separations were made with low currents (0.3 ampere) and with high currents (5 amperes).

The results show that low currents are preferable for the deposition of cadmium when organic electrolytes are used. It was observed that each electrolyte exerts a marked influence on the character of the deposit. The best deposits were obtained in presence of a mixture of ions, and especially in presence of the sulphate ion. * The formate ion exercises a good influence on the character of the deposit, cadmium acetate solution with the formate electrolyte, and cadmium formate solution with the lactate electrolyte, giving satisfactory results, even in presence of the alkaline-earth metals. The acetate and lactate electrolytes when used alone were not so successful.

E. G.

Colorimetric Estimation of Lead in Potable Water. K. SCHERINGA (*Pharm. Weekblad*, 1910, 47, 1212—1213. Compare Egeling, *Abstr.*, 1907, ii, 398).—From the results of experiments, the author concludes that Egeling's colorimetric method for the estimation of lead in potable water is untrustworthy.

A. J. W.

Electrolytic Separations. IRVING H. BUCKMINSTER and EDGAR F. SMITH (*J. Amer. Chem. Soc.*, 1910, 32, 1471—1477).—The results of a large number of experiments relating to the separation of pairs of metals by electrolysis are communicated. The conditions under which the following separations were effected are briefly described: Mercury and bismuth from nickel in presence of sulphuric acid; copper, mercury, and lead from nickel in presence of nitric acid; zinc from nickel in an alkaline tartrate solution; copper from nickel in presence of free phosphoric acid. Silver also can be separated from nickel in presence of free nitric acid if a little alcohol is added to the solution. In the separation of nickel from aluminium in an ammoniacal ammonium sulphate solution, the deposited nickel is contaminated with aluminium hydroxide; if, however, a little sodium hydroxide is added, the hydroxide is dissolved, and good results are obtained. Nickel can also be separated from magnesium, and the alkaline-earth metals in an ammoniacal ammonium salt solution. From this solution nickel is not deposited if chromium or cobalt salts are present, and it has been found that cobalt-ammonia compounds are formed in the latter case.

Other experiments have reference to the deposition of zinc from a cyanide solution, the separation of silver and mercury from bismuth in nitric acid solution, of uranium from zinc, and of cobalt and nickel from uranium.

H. M. D.

Conditions Affecting the Electrolytic Estimation of Copper. WALTER C. BLASDALE and W. CRUES (*J. Amer. Chem. Soc.*, 1910, 32, 1264—1277).—The difficulties encountered in the application of the

electrolytic method to the analysis of pyritiferous ores are enumerated, and means are indicated for overcoming them.

When 1 gram samples of such ores are used, the resulting solution may possibly contain 0.2 gram of copper, 0.4 gram of iron, and variable quantities of zinc, arsenic, and lead. If arsenic is absent, the copper can be completely separated within ninety minutes by the use of the Winkler electrode and a current of 0.75 ampere, provided that the volume does not exceed 100 c.c. and the solution does not contain any nitric acid or more than 5 c.c. of concentrated sulphuric acid. If arsenic is present, the solution should be electrolysed under the conditions already specified, and the deposit dissolved in nitric acid and again electrolysed; or, if the amount of arsenic is small, good results can be obtained by a single precipitation if 1–2 c.c. of nitric acid and 5 grams of carbamide are added to the solution. E. G.

Collection of Colloidal Precipitates. MORTON LIEBSCHUTZ (*Chem. News*, 1910, 102, 213).—In the analysis of bronzes, the tendency of metastannic acid to pass through the filter may be overcome by heating it with a dilute solution of albumin, which coagulates the colloidal precipitate. The latter has afterwards to be boiled with dilute nitric acid to remove adsorbed copper.

In separating zinc and copper by the cyanide method, the copper cyanide is removed by decantation, and to the solution containing the zinc sulphide in suspension, a little lead acetate is added. The zinc and lead sulphides can then readily be collected; the former is dissolved by boiling with dilute hydrochloric acid, and titrated with potassium ferrocyanide. G. S.

Estimation of "Carborundum" in Fragments of Coke Crucibles. HENRYK WDOWISZEWSKI (*Chem. Zeit.*, 1910, 34, 1200–1210).—One gram of the finely-powdered material is ignited to burn the coke, and the weighed residue is analysed as usual for silica and bases. If carborundum is present, it is obvious that the sum total of the various constituents must exceed 100%; by multiplying the excess by two, the amount of carborundum is obtained.

The accuracy of the result, of course, depends on the care bestowed on the analytical operations. L. DE K.

Assay of Aluminium Ores. JUAN CALAFAT Y LEÓN (*Anal. Fis. Quim.*, 1910, 8, 281–286).—To ascertain whether a mineral is suitable as a source of aluminium, roughly 0.5 gram of the finely powdered substance is intimately mixed with an equal volume of powdered anhydrous sodium carbonate and heated on charcoal in an oxidising flame during several minutes. The product is extracted with water, the solution filtered, and carbon dioxide passed through the filtrate. If the ore is of any value as a source of aluminium, the carbon dioxide will precipitate aluminium hydroxide from the solution of aluminate. The method can be made roughly quantitative by comparing the height of the precipitate obtained after settling in a tube of fixed diameter with that obtained from 0.5 gram of bauxite under similar conditions. The method is very rapid, and is useful when a large number of

minerals have to be examined to ascertain their fitness as ores of aluminium. Ordinary clay, kaolin, and other forms of aluminium silicate do not indicate the presence of alumina in this test.

W. A. D.

Detection and Estimation of Manganese in Wine. DUMITRESCU and (Mlle.) E. NICOLAU (*Ann. Falsif.*, 1910, 3, 407—410).—When the ash of a wine containing manganese is heated with ammonium persulphate solution in the presence of a trace of cobalt nitrate, the pink permanganate coloration obtained is not proportional to the amount of manganese present, as the latter is partly precipitated as its hydroxide. It is therefore recommended that the heating be prolonged for thirty minutes, and that the cobalt nitrate be omitted when it is desired to estimate the quantity of manganese present. Under these conditions the whole of the manganese is precipitated, and may be collected and weighed. The authors have estimated the quantity of manganese in 52 samples of various white and red wines, the quantities found varying from 1.8 to 27 mg. per litre.

W. P. S.

Electrolytic Separation of Nickel and Cobalt. PIERRE BRUYLANTS (*Bull. Soc. chim. Belg.*, 1910, 24, 367—372).—The description given by Piñera Alvarez of his method for the electrolytic separation of nickel and cobalt is not detailed enough, and the author has not been able to obtain satisfactory results. Both the metal deposited and the solution remaining after electrolysis contained nickel and cobalt, and the results are not even approximately accurate.

The following method is suggested: To a solution containing the sulphates of nickel and cobalt is added potassium cyanide until the precipitate first formed just redissolves. The solution is then oxidised with bromine water and acid added. The nickel ions thus produced form nickel cobalticyanide, which is insoluble in acids, but soluble in ammonium hydroxide, giving a solution containing the ions $\text{Ni}(\text{NH}_4)_4^{++}$ and $\text{Co}(\text{CN})_6^{--}$. Electrolysis of the resulting solution, using Sand's apparatus and a graded potential, leads to the deposition of nickel, but in all the experiments so far carried out the nickel has contained 2—4% of cobalt.

T. S. P.

Estimation of the Amount of Molybdenum in Calcium Molybdate. WOLDEMAR TRAUTMANN (*Zeitsch. angew. Chem.*, 1910, 23, 1981).—0.5 Gram of the finely-powdered compound is boiled with 20 c.c. of strong hydrochloric acid and 1—2 c.c. of strong nitric acid. The solution is diluted to 150 c.c., and, without filtering, poured into an excess of ammonia, to which a few c.c. of yellow ammonium sulphide have been added. After heating for a few minutes on the water-bath, the solution is filtered, and the undissolved matter is washed with dilute ammonia containing a little ammonium sulphide. From the filtrate the molybdenum trisulphide is recovered by adding dilute hydrochloric acid, and it is then converted in the usual way either into molybdenum disulphide or trioxide.

L. DE K.

Estimation of Tin in White Metals by Electrolysis.
E. SCHÜRMANN (*Chem. Zeit.*, 1910, 34, 1117—1118).—One gram of the alloy is covered with 10—15 c.c. of 50% solution of tartaric acid, and nitric acid, D 1.4, is then gradually added until the metal is dissolved. The solution is then diluted to 300 c.c., heated to boiling, and the tin precipitated by adding 10 c.c. of a 25% solution of sodium hydrogen phosphate in weak nitric acid. After diluting to about 600 c.c. with boiling water, the tin phosphate is allowed to settle, the liquid is siphoned off, and the precipitate washed by decantation with 300 c.c. of a 1% solution of potassium nitrate acidified with nitric acid. The washings are heated on the water-bath, when a further deposit is obtained, which is collected on a filter, and the main precipitate is then added. When drained, the precipitate is transferred to the beaker, in which the precipitation took place, and the little remaining in the filter is dissolved by means of 25 c.c. of hot *N*-potassium hydroxide. The alkaline liquid is then poured into the beaker, and, on warming, the tin phosphate soon dissolves. The solution is now neutralised with oxalic acid solution, and another 5 grams of the solid acid are added. Into the solution, occupying about 300 c.c., is passed, at boiling heat, a rapid current of hydrogen sulphide to remove any traces of antimony and copper. The filtrate is concentrated to 150 c.c., and neutralised with 80% aqueous potassium hydroxide; another 5 c.c. of the same are then added. The solution is then submitted to electrolysis, by preference in a Frary apparatus, using a current of 6—8 amperes and 4—5 volts; the operation is ended in two to two and a-half hours.

The process is also applicable to electrolytic tin. It does not give a clear solution with the tartaric-nitric acid mixture, but this makes no difference, as the separated stannic acid is dissolved afterwards by the potassium hydroxide. L. DE K.

Estimation of Gold by means of Hydrogen Peroxide.
L. RÜSSLER (*Zeitsch. anal. Chem.*, 1910, 49, 739—740).—Gold may be estimated by reduction with hydrogen peroxide in presence of sodium hydroxide. The author states that the addition of alkali is not strictly necessary, as the reduction also takes place in acid solution, but, owing to the fact that the operation takes a great many hours, the process is not of any practical value.

In presence of lithium or, preferably, potassium carbonate, the reduction is soon completed, and this fact may be utilised for gravimetric estimations of gold. L. DE K.

Detection of Ethyl Alcohol in Presence of Methyl Alcohol.
GEORGES DENIGES (*Bull. Soc. chim.*, 1910, [iv], 7, 951—952. Compare this vol., ii, 357, 461).—The process depends on the fact that whilst bromine water has but little oxidising action on warm methyl alcohol, it converts ethyl alcohol on warming into acetaldehyde. The latter is detected by its power of restoring the colour to a solution of magenta decolorised by sodium hydrogen sulphite and hydrochloric acid. It is always advantageous to have a little methyl alcohol present, since this reacts with acetaldehyde to form dimethylacetal,

thus avoiding possible loss of the aldehyde. Details of the method of applying the test are given. T. A. H.

Estimation of Ethyl Ether and Benzene in Alcohol. HANS WOLFF (*Chem. Zeit.*, 1910, 34, 1193).—The process is similar to the one recommended by Holde and Winterfeld (*Abstr.*, 1908, ii, 435). One hundred c.c. of the spirit to be tested are diluted to D 0.96, and then submitted to distillation, the distillate being collected in a graduated cylinder. When 20 c.c. have passed over, 80 c.c. of brine are added, and the whole is thoroughly shaken. The volume of ether or benzene is then read off. The results are satisfactory, although a trifle too low, particularly in the case of ether. L. DE K.

Estimation of Phenol in the Urine of Oxen. CARL NEUBERG and A. HILDESHEIMER (*Biochem. Zeitsch.*, 1910, 28, 523—528).—Mooser's statement (this vol., ii, 1039) that phosphoric acid may be used for the direct iodometric estimation of phenol and cresol in herbivorous urine is incorrect. The older modifications of the Kessler-Penny process must be employed both for diabetic urines and the urine of herbivora (on account of the glycuronic acid, pentoses, etc., in it). W. D. H.

Analysis of Cellulose Nitrates, Glycerol Nitrates, and Other Compounds from which Nitric Acid is Liberated by Concentrated Sulphuric Acid. EMILE BRONNERT (*Bull. Soc. ind. Mulhouse*, 1910, 80, 251—259).—Stannous sulphate or stannous potassium sulphate is dissolved in 50 vol. % sulphuric acid, and a little hydrochloric acid is added to obtain a clear solution. This is then standardised as follows: 0.15 gram of pure potassium nitrate is dissolved in a few drops of water, and 50 c.c. of sulphuric acid and one drop of solution of diphenylamine are added. The tin solution is then run in from a burette until the bluish-violet colour has completely disappeared. The tin solution is then diluted with 50 vol. % sulphuric acid until it is of $N/10$ -strength.

By means of this solution, commercial nitrates, spent acids, and also nitro-compounds, such as cellulose nitrates, which liberate nitric acid when dissolved in sulphuric acid, may be readily assayed. Attention is called to the uneven composition of some samples of commercial nitro-cellulose. L. DE K.

Estimation of Sugar by Reduction of Colouring Matters. NEUMANN WENDER (*Biochem. Zeitsch.*, 1910, 28, 523—524).—A question of priority. The method described by Hasselbalch and Lindhard (this vol., ii, 905) as new, has been in use for many years (Crismer, 1888; Wender, 1890). W. D. H.

A Simple Method for the Estimation of Sugar in the Blood. II. The Sugar in the Blood. K. MÖCKEL and E. FRANK (*Zeitsch. physiol. Chem.*, 1910, 69, 85—88. Compare this vol., ii, 554).—By care in one or two points of detail, the method previously described can be utilised for the correct estimation of sugar in the blood, as well as in serum. W. D. H.

The Reducing Substances of Urine. CASIMIR FUNK (*Zeitsch. physiol. Chem.*, 1910, 69, 72—75. Compare Abstr., 1909, ii, 902).—When known weights of dextrose are added to urine and the mixture titrated by Bertrand's method (Abstr., 1907, ii, 136), the amounts of dextrose found agree extremely well with the amounts added. When blood charcoal is used as a clarifying material before the estimation, the results are apt to come low. The addition of concentrated solutions of uric acid, creatinine, or urochrome to solutions of dextrose does not interfere with the estimation of the sugar; the reduction is the sum of the reductions of the dextrose and of the nitrogen compound. A loss is found, however, in working with dilute solutions, and this loss increases with the dilution. This is attributed to the diminution of the reduction of uric acid, urochrome, and especially of creatinine with an increase in dilution. This accounts for the fact that these substances possess no reducing properties in urine. The author suggests that the amount of creatinine present in normal urine is less than that usually accepted (0.6–2.1 grams per day), as normal urine shows no reducing action, whereas a solution containing this amount of creatinine is strongly reducing. J. J. S.

Reactions of Carbohydrates. I. Sucrose. C. REICHARD (*Pharm. Zentr.-h.*, 1910, 51, 979–986).—A detailed description is given of the colour and other changes which take place when various reagents are allowed to react with solid sucrose.

Sulphuric, nitric, or hydrochloric acid, in the cold, converts sugar into a sticky mass, which does not dry on exposure to air. Sulphuric acid does not cause the separation of carbonaceous matter unless the preparation is heated. The green mixture of cupric sulphate and hydrochloric acid remains bright green much longer when sucrose is present. Sucrose inhibits to some extent the precipitation of mercurous chloride when hydrochloric acid is added to mercurous nitrate. A mixture of sodium arsenate with hydrochloric acid and sucrose gives a stable rose-red coloration. In presence of hydrochloric acid, sucrose gives a dark green coloration with potassium dichromate, blue with ammonium molybdate, and brown, changing to violet, with ammonium vanadate, but no coloration with sodium tungstate or with titanous acid in presence of sulphuric acid. A number of colour reactions with organic substances are also described, the most interesting of these are the red coloration given with tannic acid in presence of hydrochloric acid, and the gooseberry-red tint obtained with resorcinol and hydrochloric acid. The last two reactions and that with arsenic acid may be suitable for the detection of sucrose.

T. A. H.

Detection of Dextrin by means of its Coloration by Iodine. GEORGES RIVAT (*Chem. Zeit.*, 1910, 34, 1141).—Whilst a 1% iodine solution in water gives blue colorations of equal intensity with pure starch or with a mixture of starch and dextrin, a solution of 0.00012 gram of iodine in 1 c.c. of water gives a blue coloration at once with pure starch, but not with a mixture of starch and dextrin. In

the latter case the quantity of iodine that must be added before a blue tint is developed seems to vary with the amount of dextrin present. The observation may prove on further investigation to be the basis of a method of examining mixtures of starch with dextrins.

T. A. H.

Modification of the Phenylhydrazine Reaction. JACOB BÖESEKEN (*Chem. Weekblad*, 1910, 7, 934).—As a substitute for phenylhydrazine, the author employs a solution of the base in sulphurous acid, which will dissolve up to 10%. This solution contains compounds of the formulae $C_6H_5N_2H_3SO_2$ and $(C_6H_5N_2H_3)_2SO_2$, and is prepared by passing washed sulphur dioxide through a mixture of phenylhydrazine and the requisite quantity of water until solution is complete. At first a crystalline compound separates, but on further passage of the gas, it re-dissolves. Impurities are then filtered off. The reagent reacts at once with soluble aldehydes and ketones, and, on warming, with insoluble carbonyl compounds, the hydrazones being obtained in the pure state. Its efficacy has been tested with formaldehyde, acetaldehyde, acetone, benzaldehyde, *m*-nitrobenzaldehyde, acetophenone, cuminaldehyde, furfuraldehyde, *p*-chloroacetophenone, levulinic acid, acetylacetone, acetonylacetone, and ethyl acetoacetate.

When warmed with monoses at 80°, the reagent yields pure osazones. It has been tested with dextrose, levulose, *d*-galactose, *d*-mannose, *l*-xylose, and rhamnose.

A. J. W.

New Method for Estimating Volatile Fatty Acids. ERNST WELDE (*Biochem. Zeitsch.*, 1910, 28, 501—522).—This is a method of steam distillation in a vacuum. The distillation lasts two hours; the temperature is 60°; proteins, fats, and carbohydrates remain unaltered, and bacterial action is inhibited. If acid is not added, the distillate contains the free volatile acids; if phosphoric acid is added, the total volatile acids are obtained. Illustrative experiments with milk, and contents of stomach and intestine are appended.

W. D. H.

Estimation of Formic Acid [in Formates]. ALFRED F. JOSEPH (*J. Soc. Chem. Ind.*, 1910, 29, 1189—1190).—The process is based on the oxidation of formic acid by bromine water and the formation of free hydrobromic acid.

A few grams of the formate are dissolved to 200 c.c. of water, and, if necessary, made exactly neutral. Ten c.c. of the liquid are heated to boiling, and bromine water is added until the colour no longer disappears. The excess of bromine is then expelled by boiling, and the liquid titrated as usual with standard alkali. In the case of sodium formate, 1 mol. of hydrogen bromide = 1 mol. of formic acid. A correction should be made for any acidity present in the bromine water employed.

In the presence of acetic acid, the titration process cannot be employed, but the formic acid may be calculated from the amount of total bromine left after boiling; this is best estimated by Volhard's thiocyanate method. In the case of sodium formate, 2 atms. of bromine = 1 mol. of formic acid.

L. DE K.

Fission of Chloroform and Carbon Dioxide from Trichloroacetic Acid. ROBERT STOLLÉ (*Ber. Deut. pharm. Ges.*, 1910, 20, 371—372).—When trichloroacetic acid is heated in the presence of water and antipyrine, carbon dioxide and chloroform are evolved, and the latter substance may be detected by its odour. As a test for trichloroacetic acid, the author considers the use of antipyrine to be preferable to potassium hydroxide, as prescribed by the German Pharmacopœia, or to aniline (*Abstr.*, 1906, i, 159); boiling with an excess of potassium hydroxide would not distinguish between trichloroacetic acid and chloral hydrate, whilst aniline has an odour which might mask that of the liberated chloroform. The author has prepared antipyrine trichloroacetate, m. p. 75°; it is a crystalline substance and is unstable. W. P. S.

A Reaction of Nopio Acid. ODDULIO FERNÁNDEZ (*Anal. Fis. Quim.*, 1910, 8, 328—331).—To the solution of sodium nopate in a porcelain dish, 0.1 gram of resorcinol is added, and then 10—15 grams of concentrated sulphuric acid are poured gently on to the mixture. On gently warming for a few minutes, a violet coloration appears at the zone of contact of the two liquids, which changes first to intense blue and then to green, which persists. The above colour indication is given only by resorcinol, not by the isomeric dihydroxybenzenes, or by ordinary phenol, thymol, the naphthols, etc. The trihydroxybenzenes also fail to give a coloration, with the exception of p-borogluic acid, which produces an intensely yellow coloration. The blue substance produced by sodium nopate in this test is insoluble in ether, is destroyed by water, and turns yellowish-red in presence of amyl alcohol. Some suggestions are given as to its possible nature. W. A. D.

Colorimetric Estimation of Hydrogen Cyanide. A. CHASTON CHAPMAN (*Analyst*, 1910, 35, 469—475).—The author shows that when a cyanide is treated with alkaline picrate solution, the product of the reaction may be either potassium isopurpurate or alkali salts of nitroamino-phenols; the isopurpurate is formed only when the cyanide is in excess, whilst an excess of picrate results in the formation of the nitroamino-phenols. In testing for cyanides, the picrate is usually in excess, and isopurpurate is not formed. The production of the nitroamino-phenols is the result of the reducing action of the cyanide, but other substances, such as acetone, aldehyde, hydrogen sulphide, etc., are also capable of reducing the picrate. If the reaction be employed for the colorimetric estimation of hydrogen cyanide, steps must be taken to prove that the coloration obtained is due to the presence of this substance alone. Small quantities of hydrogen cyanide may, however, be estimated by the process, provided that certain definite conditions prescribed by the author be observed, but the test has, for the reasons mentioned, a very limited sphere of usefulness.

W. P. S.

Volumetric Estimation of Hydrogen Cyanide, Especially in and with Benzaldehydecyanohydrin. LEOPOLD ROSENTHALER (*Arch. Pharm.*, 1910, 248, 529—533).—The process is a modification

of Andrews' method (Abstr., 1903, ii, 695). The indicator, iodo eosin and ether, is not affected by hydrogen cyanide, but is changed by the hydrochloric acid liberated in accordance with the equation:

The solution under examination, containing not more than 1% of hydrogen cyanide, is treated with *N*/10-sulphuric acid or potassium hydroxide in the presence of the indicator until the aqueous liquid is just rose-coloured. A solution of mercuric chloride (27.1 grams of mercuric chloride and 11.7 grams of sodium chloride in 500 grams of water), neutral to the indicator, is added, and the mixture is at once titrated, with shaking, with *N*/10-potassium hydroxide until the rose tint is restored in the aqueous liquid.

The total hydrogen cyanide in a solution containing benzaldehyde-cyanohydrin and free hydrogen cyanide is estimated as follows. The solution is first made neutral to the indicator. Then such an excess of *N*/10-potassium hydroxide is added that after shaking vigorously for a minute adding the mercuric chloride solution, and again shaking for a minute, the aqueous liquid is coloured strongly red; *N*/10 acid is added until the colour has disappeared, and the end-point is finally obtained by titrating back with *N*/10-alkali. The changes are shown by the equations: (i) $\text{HCN} + \text{KOH} = \text{KCN} + \text{H}_2\text{O}$; (ii) $\text{KOH} + \text{CHPh}(\text{OH})\cdot\text{CN} = \text{KCN} + \text{Ph}\cdot\text{CHO} + \text{H}_2\text{O}$; (iii) $2\text{KCN} + \text{HgCl}_2 = \text{Hg}(\text{CN})_2 + 2\text{KCl}$.

The estimation of the free hydrogen cyanide in a solution containing hydrogen cyanide and benzaldehyde-cyanohydrin is performed as follows. Ten c.c. of the solution are run into a separating funnel containing about 20 c.c. of a neutralised, saturated solution of sodium sulphate (in which benzaldehyde-cyanohydrin is practically insoluble), 50 c.c. of ether and 10 drops of the 0.2% alcoholic iodo eosin are added, and the mixture is rendered neutral. After adding the mercuric chloride solution, the mixture is shaken thoroughly, and the aqueous layer is run into a vessel containing neutralised distilled water; the separating funnel is rinsed with a little sodium sulphate, and its contents are again shaken with 20 c.c. of the same solution. The aqueous liquid is run off, and, after again rinsing the funnel, the combined aqueous extracts, which contain an amount of hydrochloric acid equivalent to the free hydrogen cyanide in the original solution, are titrated with *N*/10-alkali as in the first case above. C. S.

Estimation of Citric Acid in Lemon Juice and Commercial Citrates. MATTEO SPICA (*Chem. Zeit.*, 1910, 34, 1141—1143).—The method depends on the measurement of the volume of carbon monoxide produced when citric acid is heated with sulphuric acid, and a special apparatus for the purpose is described.

An Erlenmeyer flask is closed by a hollow glass stopper forming part of the continuation of an open cylindrical dropping funnel, provided with a three-way cock, and passing through this a glass tube prolonged into the flask, whereby a stream of carbon dioxide can be introduced and passed through the flask. The terminal opening of the three-way cock is connected to a nitrometer. For each estimation, 2 grams of the citrate are placed in the flask, a little water added, and then carbon

dioxide is passed through until all air is expelled, as shown by complete absorption of the issuing gas in potassium hydroxide solution. Sulphuric acid (25 c.c.) is then run in from the dropping funnel, and carefully mixed with the citrate by shaking. The mixture is heated at from 80° to 100° and shaken continuously, the current of carbon dioxide being still maintained, and the issuing gas collected and measured with the usual precautions in the nitrometer filled with potassium hydroxide solution. One c.c. of carbon monoxide at 0°/760 mm. is equivalent to 0.009407 gram of citric acid. Carbonates may be estimated in commercial citrate by placing the weighed citrate in the flask, connecting up to a nitrometer filled with water, adding 25 c.c. of hydrochloric acid, and collecting and measuring the displaced air, which, after deducting 25 c.c. for the acid added, gives the volume of carbon dioxide formed.

T. A. H.

Characterisation of Glycuronic Acid in Urine. R. BERNIER (*J. Pharm. Chim.*, 1910, [vii], 2, 401—406).—Directions are given for the detection of glycuronic acid in urine by means of Tollens and Rorive's naphtharesorcinol reaction (*Abstr.*, 1908, ii, 638; compare Mandel and Neuberg, *ibid.*, ii, 993), and by means of phenylhydrazine (Grimbert and Bernier, this vol., ii, 163, and Grimbert and Turpaud, *ibid.*, ii, 979).

Tollens and Rorive's reaction may be vitiated by the presence of indoxyl, and to avoid this difficulty the urine should first be defaecated with mercuric acetate. All the urines tested gave positive results with this reaction, thus affording a further proof that glycuronic acid is a normal constituent.

T. A. H.

Detection of Benzoic Acid in Meats and Fats. KARL FISCHER and O. GUENERT (*Zeitsch. Nahr. Genussm.*, 1910, 20, 580—583).—The following process for separating benzoic acid from a sample of meat or fat is described as being more useful and trustworthy than that described previously by the authors (*Abstr.*, 1909, ii, 708); it is a modification of the process recommended by von der Heide and Jakob (this vol., ii, 359). Fifty grams of the material are heated with 150 c.c. of a 1% sodium hydrogen carbonate solution, the aqueous layer is then separated, neutralised with sulphuric acid, and treated with copper sulphate and sodium hydroxide. The mixture is then rendered slightly acid, filtered, the filtrate is acidified with sulphuric acid, and extracted with ether. The ethereal extract is now evaporated, and the residue obtained is tested for the presence of benzoic acid. For this purpose the test proposed by Jonescu (this vol., ii, 527) is the most trustworthy; it will detect the presence of 0.006% of benzoic acid in butter. Care must, however, be taken that only 1 mg. or so of the acid be employed in the test, and that a minimum quantity of hydrogen peroxide be used. The authors find that Robin's modification of Halphen's test is not suitable for identifying the benzoic acid extracted from fats, although it is capable of detecting very small quantities of pure benzoic acid.

W. P. S.

Absorption Spectrum of Oils. RÉNE MARCILLE (*Ann. Falsif.*, 910, 3, 423—425).—The absorption spectrum of certain oils is due to

the presence of chlorophyll or its derivatives, the bands observed corresponding with the spectrum exhibited by this substance. Olive oil shows three bands, the principal one being at λ 665, whilst cotton-seed oil and sesamé oils show feeble absorption bands. Other oils, as a rule, do not exhibit absorption spectra unless they contain chlorophyll; this is sometimes the case with commercial linseed oil and castor oil. When the oils are heated with water, the position of the absorption bands is altered slightly.

W. P. S.

Primary and Secondary Bromine Numbers of Oils. WILHELM VAUBEL (*Zeitsch. angew. Chem.*, 1910, 23, 2077—2078).—When a drying oil is dissolved in a suitable solvent and the solution treated with successive small quantities of bromine, the latter is absorbed until a point is reached where a trace of free bromine remains in the solution; the quantity of bromine thus absorbed constitutes the primary bromine number of the oil. A considerable excess of bromine must then be added in order that the oil may absorb a quantity of bromine corresponding with complete saturation of the oil. The following results were obtained with various oils: linseed oil, primary bromine number, 75.7; secondary number, 107.7; wood oil, primary number, 57.0; secondary number, 94.6; earthnut oil, primary number, 52.0; secondary number, 57.6. Non-drying oils do not give a primary bromine number. When calculated into iodine, the secondary or total bromine number of drying oils corresponds closely with the iodine number as estimated directly. The author discusses the relation of the primary and secondary bromine numbers to the composition of the oils.

W. P. S.

Substitution of the Iodine Numbers of Fats by the Bromine Numbers. WILHELM VAUBEL (*Zeitsch. angew. Chem.*, 1910, 23, 2078—2080).—The author recommends that the bromine numbers of fats and oils be estimated in place of the usual iodine numbers, as the former number is more quickly obtained, and the results are trustworthy. The fat or oil should be dissolved in a somewhat large quantity of carbon tetrachloride, potassium bromide solution and water are then added, the mixture is acidified with hydrochloric acid, and, after the addition of a small crystal of potassium iodide, an excess of potassium bromate solution is introduced. The whole is well shaken in a stoppered flask for one minute, and the excess of bromine is titrated with sodium sulphite solution. The trace of iodine added as iodide serves as the indicator in the titration.

W. P. S.

Analysis of Oils. RENÉ MARCILLE (*Ann. Faleif*, 1910, 3, 417—423).—The author recommends the Wys method for obtaining the iodine numbers of oils in preference to the Hübl method; the results yielded by the latter process vary according to the age of the reagent, the temperature at which the experiment is made, etc. Directions are given for preparing the Wys reagent and for estimating the iodine numbers of oils; the separation of the fluid fatty acids from an oil and the determination of the Tortelli number are also described.

W. P. S.

Halphen's Reaction [for Cottonseed Oil]. LEOPOLD ROSENTHALER (*Zeitsch. Nahr. Genussm.*, 1910, 20, 453—454).—The amyl alcohol used in this test may be replaced by either methyl, ethyl, propyl, isobutyl, benzyl, or allyl alcohols, amylene hydrate (tertiary amyl alcohol), or santalol, but not by aldehydes, ethyl acetate, phytosterol, benzene, phenol, nitrobenzene, aniline, or acetic acid. When cottonseed oil is heated with a solution of sulphur in carbon disulphide, but without the addition of any alcohol, the characteristic coloration is not obtained; if the mixture is heated for a considerable length of time, a faint coloration may be obtained, but this is probably due to partial hydrolysis of the fat with the liberation of glycerol, which latter substance itself, when used in place of amyl alcohol, causes a coloration to be produced after thirty minutes' heating. A faint coloration also develops when ethylene glycol is employed. The solution of sulphur in carbon disulphide cannot be replaced by other sulphur compounds, such as allylthiocarbimide, potassium xanthate, disulphones, etc.

W. P. S.

The Kumawaga-Suto Method of Estimating Fats. YOSHITAKA SHIMIDZU (*Biochem. Zeitsch.*, 1910, 28, 237—273).—The process of drying material which contains water leads to a loss of fat (10% or more), doubtless due to oxidation. The material should therefore be directly saponified by the Kumawaga-Suto method. Illustrative experiments with muscle, liver, blood, etc., are given.

W. D. H.

Method for the Analysis of Fats by the Separation of the Solid Fatty Acids from the Liquid Acids. DAVID (*Compt. rend.*, 1910, 151, 756—757).—The method is based on the observation that the ammonium salts of the solid fatty acids are quite insoluble in large excess of aqueous ammonia at 14—15°, whilst the ammonium salts of the liquid acids are soluble.

A mixture of solid and liquid acids can be separated by dissolving 2 grams in 5 c.c. of warm 95% alcohol; 50 c.c. of pure ammonia are added, and the solution warmed until bubbles of gas begin to be evolved. After remaining several hours at a temperature not exceeding 15°, the liquid is filtered, the ammonium stearate or palmitate washed with ammonia until the filtrate gives no turbidity with barium hydroxide, and then treated on the filter with hydrochloric acid diluted with its own volume of water at 22°. The fatty acids are washed with hydrochloric acid, and finally with water, dried at 100°, and weighed. The experimental error does not exceed 0.2—0.3%.

The process is applicable to mixtures containing other solid acids, such as hydroxystearic, isoleic, lauric, and arachidic acids, and is believed to be of general application.

The Electrical Conductivity of Milk, and the Use of this Constant for the Detection of Watering and Addition of Electrolytes. RINALDO BINAGHI (*Biochem. Zeitsch.*, 1910, 29, 60—78).—The electrical conductivity of fresh unadulterated milk is approximately a constant for each species. For milk of sheep, $K_{25}(\text{mean}) = 50.40 \times 10^{-4}$; for that of goat, 49.00×10^{-4} ; for cow's milk, 48.70×10^{-4} . The

conductivity diminishes in proportion to the water added. Electrolytes which are added for preservative purposes (borates, etc.) increase the conductivity. The measurement of this constant is recommended for detecting adulteration and addition of preservatives. S. B. S.

The Tests for Purity of Quinine Salts. FRANK TUTIN (*Pharm. Journ.*, 1909, [iv], 29, 600—603).—The methods adopted by the various national pharmacopœias for the detection of impurities in quinine salts are of two kinds: (1) the ammonia test, and (2) specific tests for certain impurities. The author has investigated the effects of various conditions on the results obtained by the application of these two kinds of tests, more particularly as regards the former, and finds that the best method of carrying out the ammonia test is that prescribed in the French Codex, which, however, is only applicable to quinine sulphate. The ammonia test being of limited applicability, the test for cinchonine and cinchonidine prescribed by the British Pharmacopœia is preferable, since it can be used for any quinine salt. The following general conclusions are drawn.

The minimum amount of 10% ammonia solution which will yield a clear solution at 15° with 5 c.c. of a solution of quinine sulphate saturated at 15° is 4.4 c.c., so that it is impossible to meet the requirements of the German Pharmacopœia, which stipulates 4 c.c. of ammonia solution. A reasonable requirement for commercial quinine sulphate would be 6.0 c.c. The quantity of ammonia needed is affected by the alkalinity or acidity of the quinine sulphate used, so that it is not a trustworthy indication of the presence of other alkaloids. In this connexion it is pointed out that solutions of commercial quinine sulphate in water are usually slightly alkaline, and become more so on heating, reverting to their original slight alkalinity on cooling. In applying the ammonia test to quinine salts other than the sulphate, it is usual to convert them into the sulphate in such a way that the test is made in presence of an inorganic salt. The presence of the latter profoundly influences the quantity of ammonia needed, so that the test becomes untrustworthy. For this reason the specific test for cinchonine and cinchonidine prescribed by the British Pharmacopœia is more satisfactory, but in applying it "Aether purificatus," not "Aether," of the Pharmacopœia should be used. The ammonia test is, however, the only one available for the detection of hydroquinine, but it is not yet certain that minute quantities of hydroquinine sulphate are objectionable in quinine sulphate. The specific rotations quoted in the French Codex for several quinine salts are not in harmony with each other, and could not be confirmed.

The following new salts were prepared: Quinine d-camphor-sulphonate, m. p. 191°, colourless needles from water or dilute alcohol. Quinine d-bromocamphorsulphonate, m. p. 260° (decomp.), crystalline from dilute alcohol, but is insoluble in water. Hydroquinine d-camphor-sulphonate, m. p. 217—218°, and d-bromocamphorsulphonate, m. p. 266°, are both crystalline. T. A. H.

INDEX OF AUTHORS' NAMES.

INDEX OF SUBJECTS.

TRANSACTIONS, PROCEEDINGS, AND ABSTRACTS.

1910.

(Marked T, P., and A., i and A., ii respectively.)

- A.**
- Abietic acid**, *tetrahydroxy-*, and its silver and barium salts (LEVY), A., i, 11.
- Absorption and digestion** (LONDON; LONDON and RABINOWITZ; LONDON and DORROWOLSKAJA; LONDON and SAGELMANN; LONDON and RIVOSCH-SANDBERG; LONDON and DMITRIEW), A., ii, 422; (LONDON and SCHWARZ; LONDON and GOLDBERG; LONDON and KORCHOW), A., ii, 972.
- apparatus** (BERL), A., ii, 588.
- Absorption spectra**. See under Photochemistry.
- Acapnia and shock** (HENDERSON), A., ii, 137, 227, 1093; (HENDERSON and McRAE), A., ii, 622.
- α - and β -Acetacopalonic acids** (KAHAN), A., i, 690.
- Acetacopalic acid** (KAHAN), A., i, 690.
- Acetacopalinic acid** (KAHAN), A., i, 690.
- α - and β -Acetacopalic acids** (KAHAN), A., i, 690.
- α -, β -, and γ -Acetacopalorazines** (KAHAN), A., i, 690.
- Accumulator**. See under Electrochemistry.
- Acenaphthaphenazineazine** (ULLMANN and CASSIRER), A., i, 202.
- Acenaphthene**, 4-iodo- (SACHS and MOSEBACH), A., i, 726.
- and its picrate (CROMPTON and HARRISON), T., 226.
- Acenaphthanthraquinone**, derivatives of (KALE & Co.), A., i, 751; (ZUFFA), A., i, 861.
- Acetal**, chloroacetyl-amino- and glycyloamino- (HARRIES and PETERSEN), A., i, 228.
- Acetaldehyde**, formation of, in wine (TRILLAT), A., ii, 232; (TRILLAT and SAUTON), A., ii, 438.
- action of the electric discharge on, in the presence of hydrogen (BESSON and FOURNIER), A., i, 461.
- and ethyl alcohol, the system (SMITS and DE LEEUW), A., i, 816.
- paracetaldehyde and metacetaldehyde, the system (SMITS and DE LEEUW), A., i, 815.
- oxidation of, by lower vegetation (FERRIER), A., ii, 799.
- detection of formaldehyde in the presence of (DENIGES), A., ii, 357.
- Acetaldehyde**, glycyloamino-, synthesis of (HARRIES and PETERSEN), A., i, 228.
- tri-chloro-*. See Chloral.
- Acetamida**, derivatives of, influence of negative atoms and groups in (STEINKOPF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 305.
- Acetamidophosphoric acid**, chlorobromo-, diethyl ester (STEINKOPF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 308.
- Acetamido-phosphoryl**, *di*-bromonitro-, and *tri*-bromo-, *di*-chlorides, *di*- and *tri*-chloro-, *di*-chlorides, dianilides, esters and bisphenylhydrazides, *di*-chlorobromo-, and *di*-chloronitro-, *di*-chlorides and esters (STEINKOPF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 308.
- Aceto-pyridine-iron base**, salts of (WEINLAND and GUSSMAN), A., i, 635.
- Acetylpiperidylloxime** (RUSSSELL), T., 956.

- Acetic acid**, formation of, by hydrolysis of lignin (CROSS), A., i, 457.
 heat of liquefaction of (MEYER), A., ii, 182.
 ammonium salt, hydrolysis of (NOYES, KATO, and SOSMAN), A., ii, 257.
 cadmium salt, ionisation in aqueous solutions of (JACQUES), A., ii, 357.
 ethyl ester, preparation of (BOGOW-JAWLENSKI and NARRUTT), A., i, 355.
 reactions of salts in (NAUMANN, HAMERS, and HENNINGER), A., ii, 211.
o-, *m*-, and *p*-chlorophenyl and *o*-, *m*-, and *p*-bromophenyl and *p*-iodophenyl esters of (WOHLEREN), A., i, 27.
Acetic acid, bromo-, interaction of, and its sodium salt with silver salts in aqueous solution (SESTER, T., 346; P., 23).
 allyl, benzyl, *n*-butyl, and *tert*-butyl esters of (CLARKE), T., 428.
 chloro-, as a cryoscopic solvent (MAMELI), A., ii, 182.
 dichloro-, formation of, from trichloroacetaldehyde (KÖTZ), A., i, 151.
 action of, on aniline and its homologues (HELLER and ASCHKENAST), A., i, 738.
 trichloro-, reactions of (STOLLE), A., ii, 1119.
 nitro-, dipotassium salt of (STEINKOFF, BOHRMANN, GRÜNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 307.
 thiocyno-, and its ethyl ester action of hydrazines on (FRIEDRICH and FÖRSTER), A., i, 190.
 dithio-, methyl ester (Houben and SCHULTZE), A., i, 711.
Acetic anhydride, rate of hydration of (RIVETT and SIDGWICK), T., 732; P., 66.
 and its homologues, action of, on magnesium organic compounds (FOURNIER), A., i, 652.
 compounds of, with sodium salts of the fatty acids (TSAKALOTOS), A., i, 458.
Acetiminomethyl ether (MATSUI), A., i, 698.
 trichloro- (STEINKOFF, BOHRMANN, GRÜNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 306.
Acetin, α -bromo- (ALPERN and WEIZMANN), P., 345.
Aceto-. See also Acetyl, and under the parent substance.
Acetoacetic acid, formation in the liver (EMDEN and WIRTH; GRISBACH), A., ii, 789.
Acetoacetic acid, decomposition of, by enzymes of the liver (WAKEMAN and DAKIN), A., ii, 977.
 semicarbazone-semicarbazide of (CHICK and WILMORE), T., 1991; P., 217.
 ethyl ester, equilibrium isomerism of, and the isorropesis of its salt (HANTZSCH), A., i, 511.
 condensation of α - and β -naphthols with (BACOVESCU), A., i, 465.
 action of sodium alkyl oxides on (KOMNENOS), A., i, 708.
o-carboxyphenylhydrazone of (MICHAELIS, KRUG, LEO, and ZIESEL), A., i, 513.
 4-carboxyphenylhydrazone of (MICHAELIS and HORN), A., i, 517.
Acetoacetic acid, chlorocyno-, ethyl ester, sulphur derivatives (BENARY, A., i, 578).
 α -cyano- γ -thiocyno-, ethyl ester (BENARY), A., i, 581.
Acetoacetin, $\alpha\beta$ -dichloro- (ALPERN and WEIZMANN), P., 345.
Aceto-*p*-aminophenylethylamide (JOHNSON and GUEST), A., i, 319.
Acetocatechol, amino-, and its hydrochloride (FARBENFABRIKEN VON F. BAYER & CO.), A., i, 313.
Acetocellobiose, bromo-, and iodo- (FISCHER and ZEMPLEN), A., i, 713.
Acetodextrose, β -idolo- (FISCHER and FISCHER), A., i, 717.
Acetoheptadecylanilide (LE SUEUR), T., 2437.
Acetone, action of sunlight on (BAIK, A., i, 543).
 action of, on sodium phenyl carbonate (FRANCHIMONT), A., i, 4; (MOLL VAN CHARANTE and MONTAGNE), A., i, 311.
 benzoylamino- (GARRIEL), A., i, 481.
 detection of (FRITSCH), A., ii, 165; (ROSENTHALER), A., ii, 455.
 in urine, test for (BARDAUT), A., ii, 358.
 iodometric estimation of (KRAUS), A., ii, 465.
Acetone substances, influence of the diet of the food and of muscular work on the excretion of (FORSNER), A., ii, 1092.
Acetoncyanohydrin, action of hydrogen chloride on (ULFKE), A., i, 14.
Acetoneduplo-*m*-xylenesemercaptal (AUTENRIETH and BEUTTEL), A., i, 61.
Acetone-semicarbazone, oximino-, and its acetyl derivative (RIPE and KESSLER), A., i, 93.

- Acetone azo-tricarboxylic acid, methyl ester and phenylhydrazone (KOMNENOS), A., i, 541.
- Acetone *p*-tolylmercaptal (FROMM and RAIZISS), A., i, 555.
- Acetonitrile, derivatives of, influence of negative atoms and groups in (STEINKOFF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENDER), A., i, 305.
- nitro-, ammonium salt, *di*bromonitro-, and *di*chloronitro- (STEINKOFF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENDER), A., i, 307.
- Acetonitriles, arylsulphonated, condensation of aromatic aldehydes with (TRÖGER and BREMER), A., i, 113.
- o*- and *p*-Acetonitrophenylethylamide and hydrochloride of the latter (JOHNSON and GUEST), A., i, 310.
- Aceto-2,4-dinitrophenylethylamide (JOHNSON and GUEST), A., i, 310.
- Acetopentadecylanilide (LE SUEUR), T., 2459.
- Acetophenone, action of carbon disulphide and potassium hydroxide on (KELBER), A., i, 390.
- electrolytic reduction of (MÜLLER and KOPPE), A., ii, 387.
- Acetophenone, α -acetyl-amino-, and its derivatives (GABRIEL), A., i, 431.
- p*-amino-, semicarbazone, phenylhydrazone and hydrochloride, α -bromo-, and α -chloro-, semicarbazones (KNÖFFER), A., i, 433.
- ω -amino-*o*-hydroxy-, hydriodide (TUTIN), T., 2518; P., 245.
- ω -amino-*p*-hydroxy-, hydriodide (TUTIN), T., 2520.
- ω -amino-*op*-*di*hydroxy-, and its hydriodide, and other salts (TUTIN), T., 2513; P., 245.
- ω -amino-*mp*-*di*hydroxy-, hydriodide (TUTIN), T., 2520; P., 244.
- ω -benzoylamino-*op*-*di*hydroxy- (TUTIN), T., 2516.
- ω -chloro-*o*-hydroxy- (TUTIN), T., 2504.
- ω -formylamino- (PICTET and GAMS), A., i, 774.
- 3,4-*o*-*tr*hydroxy- (VOSWINCKEL), A., i, 43.
- acetophenylamidine, *trichloro*-, and its hydrochloride (STEINKOFF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENDER), A., i, 306.
- acetophenylhydrazidine hydrochloride (DIMROTH and MERZBACHER), A., i, 897.
- Aceto-*o*-toluidide, 5:6-*di*chloro-, and 6-chloro-5-bromo- (BADISCHE ANILIN- & SODA FABRIK), A., i, 271.
- Aceto-*m*-toluidide, 2:6-*di*-iodo- (WHEELER and BRAUTERCHT), A., i, 663.
- Aceto-*p*-toluidide, 3-iodo-5(?) nitro- (WHEELER and LIDDIE), A., i, 18.
- Acetotridecylanilide (LE SUEUR), T., 2440.
- Acetoveratrone, oxime, semicarbazone and pinacone of (MANNICH and NEUMANN), A., i, 412.
- α -Acetoxyacrylonitrile (DEAKIN and WILSMORE), T., 1969; P., 216.
- o*-, *m*-, and *p*-Acetoxy- ϕ -allyltoluene (GUILLAUMIN), A., i, 477.
- α -Acetoxybenzoic acid, ω -trichloro-, preparation of (CHEMISCHE FABRIK VON HEYDEN), A., i, 37.
- ω -iodo- (CHEMISCHE FABRIK VON HEYDEN), A., i, 485.
- 5-iodo- (HAASE), A., i, 710.
- p*-Acetoxybenzoic acid (RIEDEL), A., i, 765.
- α -Acetoxybenzoic anhydride (EINHORN), A., i, 741.
- p*-Acetoxybenzoyl chloride (RIEDEL), A., i, 765.
- α -Acetoxybenzoylcarboxylic acid, ethyl ester (EINHORN), A., i, 741.
- p*-Acetoxybenzoylmorphine and its methochloride (RIEDEL), A., i, 765.
- 2- α -Acetoxybenzoyloxybenzoic acid, (*acetylalicycloalicyclic acid*) (BOEHMINGER & SÖHNE), A., i, 386.
- 1- α -Acetoxybenzyl 2 naphthol-3 carboxylic acid, methyl ester of (FRIEDL), A., i, 742.
- α -Acetoxycinamic acid (DIECKMANN), A., i, 384.
- 2 Acetoxycoumaran, 4:6-*di*bromo- (FRIES and MO-KOPP), A., i, 332.
- α -Acetoxyethylbenzene, β : β :3:5-*tetra*bromo-2-hydroxy- (FRIES and MOSKOPF), A., i, 332.
- α -Acetoxymercuri- β -ethoxy- β -phenyl-propionic acid, methyl ester and derivatives of (SCHRAUTH, SCHOELLER, and STRUENSEE), A., i, 343.
- α -Acetoxymercuri- β -methoxy- β -phenyl-propionic acid, its methyl ester and halogen and veronal derivatives (SCHRAUTH, SCHOELLER, and STRUENSEE), A., i, 347.
- 3-Acetoxy-4-methoxy-(α)-benzoylimino-cinnamic anhydride (MATTHNER), A., i, 115.
- β -Acetoxy α -methylbutyric acid, derivatives of (BLAISE and HERMAN), A., i, 534.
- 4-Acetoxy-1-methylcyclohexyl methyl ketone, oxime of (WALLACE), A., i, 569.

- 1-Acetoxy-5-methyl-2-methylene coumaran, 1:4:6-tribromo- (FRIES and VOLK), A., i, 333.
- β-Acetoxy-α-methylpropyl ethyl ketone (BLAIR and HERMAN), A., i, 534.
- 9-Acetoxyphenanthrene (SCHMIDT and SPOUN), A., i, 553.
- 10-Acetoxyphenanthrene, 3:9-dibromo-, and 3:9-dinitro- (SCHMIDT and SPOUN), A., i, 553.
- 3-Acetoxy-9-phenylflorone (POPE and HOWARD), T., 1027.
- 9-β-Acetoxyphenylflorone (BISTRZYCKI and v. WEBER), A., i, 743.
- α-Acetoxyphenylthiolacetic acid, ethyl ester (FUMMERER), A., i, 463.
- Acetyl. See also Aceto-, and under the parent substance.
- Acetyl halides, action of, on unsaturated hydrocarbons, in the presence of aluminium halides (KRAPIWIN), A., i, 349.
- Acetyl chloride, chloro-, preparation of (CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE), A., i, 650.
- Acetylacetonecarbamide. See 4:8-Dimethyl-2-pyrimidone.
- Acetylacetonephenylmethylhydrazone (v. BRAUN), A., i, 524.
- γ-Acetylalanine, behaviour of, towards dehydrating agents (ZINCKE), A., i, 557.
- Acetyl-*d*-alanyl-*l*-leucyl-*d*-isoleucine chloro- (ABDERHALDEN and HIRSCH), A., i, 720.
- Acetylalylamine, chloro- (HARRIES and PETERSEN), A., i, 228.
- Acetylamine. See under the parent substance.
- p*-Acetylanisole semicarbazone (SCHOLTZ and MEYER), A., i, 562.
- Acetylanthranil, 4- and 5-acetylamino- (BOGERT, AMEND, and CHAMBERS), A., i, 894.
- 3:5-dibromo- (WHEELER and OATES), A., i, 431.
- Acetylanthranilic acid, lactone of (MOHR and KÖHLER), A., i, 116.
- 3:5-dibromo-, and its silver salt and ethyl ester (WHEELER and OATES), A., i, 431.
- Acetylanthranoylanthranillo acid. See Benzoylanthranilic acid, acetylaminobenzoylanthranilic acid, acetylaminobenzoylanthranilic acid, acetylaminobenzoylanthranilic acid, acetylaminobenzoylanthranilic acid.
- Acetyl-*l*-aspartic acid, chloro- (FISCHER and FIEDLER), A., i, 658.
- Acetyl-*l*-aspartylglycine, chloro-, and its ethyl ester (FISCHER and FIEDLER), A., i, 657.
- Acetylbenzanilide, hydroxy- (MUMM and HESSE), A., i, 311.
- Acetylbenzidine, 2:2'- and 3:3'-dichloro- (CAIN and MAY), T., 723.
- 2-nitro- (CAIN and MAY), T., 725.
- Acetylbenz-*p*-nitroanilide (MUMM and HESSE), A., i, 311.
- 1-Acetyl-1-bromoacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 1-Acetyl-2-bromoacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 1-Acetyl-6-bromoacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 5-Acetylallocaffuric acid (DILTZ), A., i, 523.
- d*-α-Acetylcamphor-*m*-hydroxyanil (BOESCHE, SCHMIDT, TIRUTKE, and ROTTMEIER), A., i, 882.
- Acetylcarbamic acid, allyl ester and halogen-substituted propyl and isopropyl esters (JOHNSON and GREST), A., i, 886.
- 1-Acetyl-1-chloroacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 1-Acetyl-2-chloroacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 1-Acetyl-6-chloroacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 1-Acetyl-1-chlorobromoacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- 1-Acetyl-6-chlorobromoacetyl-6-methyltetrahydroquinoline (KUNCKELL), A., i, 636.
- Acetyl-*p*-cresol, 3-chloro-, anisoyl derivative of (AUWERS), A., i, 630.
- Acetyldianisidine (CAIN and MAY), T., 723.
- 2-Acetyl-5:6-dimethoxyphenoxycetic acid (v. GRAFFENRIED and v. KETANECKI), A., i, 631.
- 4-Acetyl-1:1-*d*-methyl-3-*γ*-*γ*-hexanone, and its semicarbazone (LESER), A., i, 43.
- Acetylene, critical constants of (CALDOSE and BÄRME), A., i, 603.
- adsorption of, by palladium (PANI and HÖHNESCH), A., i, 806, 807.
- lamp (TECLC), A., ii, 705.
- chloro- and bromo-mercury derivatives of (HOFMANN and KIRCHHEIMER), A., i, 16.
- Acetylenedureine, action of hypochlorous acid and its sodium salt on (DILTZ and BEHRENS), A., i, 529.
- Acetylenic compounds, hydrogenation of (LESPIEAU), A., i, 535.
- 4'-Acetyl-3-ethoxybenzidine (CAIN and MAY), T., 725.
- 2-Acetyl-4-ethoxyphenoxycetic acid (v. GRAFFENRIED and v. KETANECKI), A., i, 631.
- α-Acetylglutamic acid, ethyl ester (SIMONSEN), T., 1914.

- 2-Acetyl-1:1:3-trimethylcyclohexan-3-ol**, (LESER), A., i, 48.
- Acetylisonvanillic acid**, 2:6-dinitro- (WEGSCHEIDER and KLEMENC), A., i, 671.
- Acid**, free, of oils and fats, estimation of (MARX), A., ii, 380; (MAYER), A., ii, 361.
- $C_6H_5O_2N_2S$, from 3-amino-2-imino-4-ketotetrahydrothiophen and nitrous acid, and its lead salt (BENARY), A., i, 580.
- $C_6H_{10}O_7$, from the oxidation of dextrose, and its barium salt (NEUBERG), A., i, 711.
- $C_8H_{12}O_3$, and its ethyl ester, from polymers of crotonaldehyde (DELEFINE), A., i, 219.
- $C_8H_5O_4N$, from the oxidation of galipine (TRÖGER and MÜLLER), A., i, 415.
- $C_8H_{15}O_4Br$, derivative of crotonaldehyde polymeride (DELEFINE), A., i, 219.
- $C_8H_{11}O_4$, from 2-acetyl-1:1-dimethyl-3-cyclohexanone (LESER), A., i, 48.
- $C_8H_7O_4$, from the sodio-derivative of dimethyl α -thujadicarboxylate, and its silver salt (THOMSON), T., 1515; P., 178.
- $C_{10}H_{15}O_2$, from Manila copal (RICHMOND), A., i, 691.
- $C_{11}H_{19}O_2$, and its amide and esters, from the sodium derivative of butyrolin and of isobutyrolin (BOUVEAULT and LOCQUIN), A., i, 93.
- $C_{10}H_{14}O_4$, from the terpene from *l*-pinocampheol (GILDEMEISTER and KÖHLER), A., i, 181.
- $C_{10}H_{14}O_2$, from the action of light on camphor (CIAMICIAN and SILBER), A., i, 496.
- $C_{12}H_{17}O_8$, and its silver salt, from α -picrotinic acid (ANGELICO), A., i, 404.
- $C_{13}H_{17}O_7$, and its silver salt, from α -picrotinic acid (ANGELICO), A., i, 405.
- $C_{13}H_{19}O_2N$, from dimethylketenopyridine (STAUDINGER, KLEVER, and KOBER), A., i, 587.
- $C_{14}H_{19}O_6$, from the action of water on $C_{14}H_{13}O_5$ (FRIST and REUTER), A., i, 10.
- $C_{14}H_{21}O_2$, two isomerides, from caryophyllene glycol (HAARMANN), A., i, 496.
- $C_{15}H_{19}O_8$, from α -picrotinic acid (ANGELICO), A., i, 404.
- $C_{15}H_{19}O_4$, and its silver salt (ANGELICO), A., i, 404.
- Acid**, $C_{16}H_{17}O_4$, from ethyl benzylidene-dioxyphenylpropionate (HITTMANN), A., i, 585.
- $C_{16}H_{17}O_2N_2$, from indirubin and sodium hydroxide, and its sodium salt (FRIEDLÄNDER and SCHWENK), A., i, 592.
- $C_{16}H_{25}O_3N$, from 2:4-diketo-6-phenyl-1:3:3:5:5-pentamethylpiperidine, and its methyl ester (STAUDINGER, KLEVER, and KOBER), A., i, 588.
- $C_{17}H_{21}O_2N$, from dimethylketenquinoline (STAUDINGER, KLEVER, and KOBER), A., i, 587.
- $C_{17}H_{21}O_2N$, from dimethylketenquinoline (STAUDINGER, KLEVER, and KOBER), A., i, 587.
- $C_{17}H_{25}O_2N_2P$, from Michler's ketone and hypophosphorous acid (FOSSE), A., i, 292.
- $C_{18}H_{17}O_2N$, from oxidation of corycavinmethine (GAEBEL), A., i, 592.
- $C_{20}H_{29}O_{12}$, from ethyl-2:4-dicarboxy-dicyclo-0:1:1-butane-1:3-dimalonate, and its sodium derivative (GUTZEIT and HARTMANN), A., i, 389.
- $C_{20}H_{21}O_2N_2$, from new alkaloid of *Pseudocinchona africana*, and its silver salt (FOURNEAU), A., i, 501.
- $C_{21}H_{25}O_2N$, from dimethylketen- β -naphthaquinoline (STAUDINGER, KLEVER, and KOBER), A., i, 587.
- $C_{22}H_{25}O_4$, from Manila copal (RICHMOND), A., i, 691.
- $C_{24}H_{34}O_{10}$, and its copper and barium salts and sodium derivative (GUTZEIT and HARTMANN), A., i, 387.
- $C_{25}H_{37}O_3$, from pumpkin seed, and its ethyl ester (POWER and SALWAY), A., ii, 339.
- $C_{22}H_{35}O_4$, from Manila copal (RICHMOND), A., i, 691.
- $C_{30}H_{41}O_3$, from leaves of *Betula alba* (GRASSER and PURBERT), A., ii, 440.
- $C_{41}H_{67}O_7$, from leaves of *Betula alba*, and its potassium salt (GRASSER and PURBERT), A., ii, 440.
- Acids**, preparation of, from phenylalkyl ketones (WILLGERODT and HARRERT), A., i, 117.
- by the action of ammonium sulphide on aliphatic aromatic ketones (WILLGERODT and SCHOLTZ), A., i, 392.
- the capillary rise of (SEKAUF, KRATZ, and v. BIEHLER), A., ii, 934.
- activity of, as catalysts (DAWSON), P., 326.
- hydrolytic activities of (WORLEY), P., 298; (ARMSTRONG and WHEELER), P., 299.

- Acids**, hydrolytic activities of, depression of the, by paraffinoid alcohols and acids (ARMSTRONG and WORLEY), P., 298.
- chemical constitution and physiological action of (LOEB), A., ii, 147.
- additive compounds of ketones and quinones with (MEYER), A., i, 179.
- of the stearolic series, reduction of, and isomerism of their hydriodic derivatives (ARNAUD and POSTERNAK), A., i, 356.
- decomposition of, by ultra-violet light (BERTHELOT and GAUDECHON), A., ii, 814.
- externally compensated, resolution of (POPE and READ), T., 987; P., 118.
- and bases, the relation between the strength of, and the quantitative distribution of affinity in the molecule (FLÜRSCHIMM), T., 84.
- physiological degradation of, in animals (KNOOP), A., ii, 880.
- acetylenic, action of hydrazic acid on (OLIVERI-MANDALÀ and COPPOLA), A., i, 594.
- aromatic, catalysis of (SENDERENS), A., i, 318.
- monobasic aliphatic, action of esters of, on the sodium derivative of phenylacetonitrile (BODROUX), A., i, 623.
- polybasic, a reaction of (PICCARD), A., i, 87.
- fatty, preparation of anhydrides of, from their salts (GOLDSCHMIDT), A., i, 650.
- oxidation of phenyl derivatives of, in the animal organism (DAKIN), A., ii, 795.
- in cod-liver oil (HEIDUSCHKA and RHEINBERGER), A., i, 297.
- degradation of, in the organism (BLUM), A., ii, 520.
- metabolism of, in the liver (MOTTRAM), A., ii, 525.
- fatty, apparatus for the distillation of (BROWN and THOMAS), P., 149.
- separation of (FACHIN and DORTA), A., i, 707.
- estimation of, in faeces (FOLIN and WENTWORTH), A., ii, 757.
- estimation of, in fats (BRUNO), A., ii, 757.
- insoluble, of butter, refraction of (DUMITRESCU and POPESCU), A., ii, 566.
- fatty bromo-substituted, interaction of esters of, with silver nitrate (SENER), P., 344.
- phenylated, synthesis of (MAUTHNER), A., i, 115.
- Acids**, fatty unsaturated, conductivity measurements with (FICHTER and PROBST), A., i, 217.
- saturated fatty, general reaction for conversion of, into ketones (DAKIN), A., i, 557.
- monobasic saturated fatty, solidification of binary mixtures of, and water (BALLO), A., i, 355.
- higher fatty, carbohydrate esters of (BLOOR), A., i, 538.
- heterohydroxylic, synthesis of (BÜLOW and HAAS), A., i, 595.
- inorganic complex (MOLATI), A., ii, 309.
- isomerisable unsaturated, and their salts, molecular refraction of (HANTZSCH and MEISENBURG), A., ii, 169.
- organic, effect of temperature and dilution on, in aqueous solution (WHITE and JONES), A., ii, 13.
- velocity of electrolytic oxidation of (AGENO and DONINI), A., i, 357.
- conductivity and dissociation of (WHITE and JONES), A., ii, 821.
- behaviour of salts of, on melting (VORLANDER), A., ii, 1046.
- interchange of alkyl groups in esters of (FRANKE), A., i, 480.
- and bases, solubility of, in solutions of their salts (SINGWICK), P., 60.
- pharmacopoeial, and their salts, solubilities of (SEIDELL), A., i, 803.
- unsaturated, action of ammonia on (STADNIKOFF), A., i, 825.
- di-basic, growth of moulds in solutions of (DOX), A., ii, 994.
- hydroaromatic unsaturated (AUWERS and PETERS), A., i, 841.
- systematic detection of (MILOBENDSKI), A., ii, 154.
- volatile, estimation of, in wines (ROETIGEN), A., ii, 661.
- in fermentation products of bacteria, determination of (SELIBER), A., ii, 642.
- fatty, estimation of (WELDE), A., ii, 1118.
- See also Amino-acids, Carboxylic-acids, Hydroxy-acids, Ketonic-acids.
- Acid anhydrides**. See Anhydrides.
- Acid chlorides**, action of heat on higher fatty (BISTRZYCKI and LANDTWIN), A., i, 87.
- Acid hydrazides**, aromatic, action of alkalis on (CERTUS, MELSBECH, and RISSOM), A., i, 508.
- Aconitine**, action of, on the mammalian heart (CUSHNY), A., ii, 224.

- Acetaldehyde**, formation of, in bitter wines (VOISENET), A., ii, 733, 909.
 preparation of (SENDERENS), A., i, 651.
- Acridine perchlorate** (HOFMANN, METZLER, and HÖBOLD), A., i, 370.
- Acridonim salts**, structure of (HEWITT and THOLE), P., 225.
- Actinium** in the atmosphere (KURZ), A., ii, 476.
 ionisation of gases, by the β -rays of (KLEEMAN), A., ii, 474.
 constituents of the induced activity of (BLANQUIES), A., ii, 763.
 emanation, α particles expelled from the (GEIGER and MARSDEN), A., ii, 92.
- Acylaminophenylsulfonamido acids**, preparation of (WIEL and WEISSE), A., i, 469.
- Acylazoaryl compounds**, isomerism of (PONZIO), A., i, 192.
- Acylins**. See Hydroxy-ketones.
- Adamite** from Thasos, Turkey (ROSIČKÝ), A., ii, 309.
- Addison's disease**, metabolism in (BEUTENMÜLLER and STOLTZENBERG), A., ii, 982.
- Addition theory** (MICHAEL), A., i, 235.
- Additivity and residual affinity** (PETERS), A., ii, 114.
- Addres**, presidential (DIXON), T., 661.
- Adenase**, and its relationship to hypoxanthine in the organism (VÖGTLIN and JONES), A., ii, 631.
- Adenine**, preparation of, from beet sugar residues (ANDERLIK), A., ii, 742.
- Adeninum Hongkel poison**, from the French Soudan (PÉREOT and LEPRINCE), A., ii, 151.
- Adipic acid**, ethyl hydrogen ester and derivatives (KLATSE and KÖHLER), A., i, 297.
- Adrenalectomy and glycosuria** (McGUIGAN), A., ii, 630.
- Adrenaline** (*suprarenine*, *epinephrine*), formation of, from tyrosine (EWINS and LAIDLAW), A., i, 411.
 antagonism between the chlorides of the alkaline earths or of potassium and (FRANKL), A., ii, 59.
 influence of, on the electro-cardiogram (STRAUB), A., ii, 434.
 increase of susceptibility to, produced by cocaine (FRÖHLICH and LOEWI), A., ii, 228.
 the iodine reaction of (KRAUSS), A., ii, 82.
 inurement to (POLLAK), A., ii, 881.
 and allied bases, colour reactions of (EWINS), A., ii, 557.
 colorimetric estimation of (ZANFRONZINI), A., ii, 467.
- Adrenaline** (*suprarenine*, *epinephrine*), estimation of, in blood (TRENDELENBURG), A., ii, 971.
- Adrenaline dimethyl ether**, trimethyl ether, and its hydrochloride and hydriodide (MANNICH and NERBERG), A., i, 412.
 methylene ether, and its methyl ether (MANNICH and JACOBSON), A., i, 413.
- d-Adrenaline** (*d-suprarenine*) (WATERMAN), A., ii, 69.
- isoAdrenaline dimethyl ether**, and its hydrochloride (MANNICH and NERBERG), A., i, 412.
 methylene ether, and its hydrochloride (MANNICH and JACOBSON), A., i, 413.
- Adrenaline-mydrasia**, observations of (ZAK), A., ii, 529.
- Adrenaline series**, syntheses in the (TUTIN), T., 2495; P., 244; (MANNICH), A., i, 411.
- Adsorption**, nature of (MOORE and BILLAND), A., ii, 318.
 anomalous (BILTZ and STEINER), A., ii, 830.
 influence of chemical affinity on (VIGNON), A., ii, 1040.
 by clay (ROHLAND), A., ii, 104.
 influence of the reaction of the medium on (MICHAELIS and RONA), A., ii, 591.
 of dissolved substances (HAGLUND), A., ii, 396.
 and colloidal precipitation (MORAWITZ), A., ii, 591; (FRETCHER), A., ii, 692.
- Aesculase** (SIGMUND), A., ii, 885.
- Aesculus hippocastanum**, enzymes from (SIGMUND), A., ii, 885.
- AFFINITY, CHEMICAL:—**
- Affinity**, quantitative distribution of, in the molecule, and the relation between the strength of acids and bases (FLIESCHEIN), T., 84.
 distribution of, in unsaturated organic compounds (BORSNER), A., i, 830.
 method of measuring, between solvent and solute (v. WEIMAR), A., ii, 1045.
 chemical (BRÖNSTED), A., ii, 112.
 influence of, on adsorption (VIGNON), A., ii, 1040.
 residual, and additivity (PETERS), A., ii, 114.
- Affinity relations** of cupric oxide and cupric hydroxide (ALLMAND), T., 603; P., 55.
- Solution affinity** of sodium phosphate and water (MÜLLER), A., ii, 112.

AFFINITY, CHEMICAL:—
 Solution affinity of sulphuric acid and water (BRÖNSTED), A., ii, 112.
 Dynamic isomerism (BRITISH ASSOCIATION REPORTS), A., ii, 672.
 studies of (LOWRY, DESCH, and SOUTHGATE), T., 899; P., 68; (LOWRY and SOUTHGATE), T., 905; P., 68; (LOWRY and JOHNS), T., 2634; P., 162; (GLOVER and LOWRY), P., 162.
 Chemical dynamics of the decomposition of persulphuric acid and its salts in aqueous solution (GREEN and MASSON), T., 2083; P., 231.
 Chemical equilibrium, influence of the medium on (BUGARSKY), A., ii, 221.
 influence of centrifugal force on (DUMANSKY), A., ii, 112.
 influence of insoluble salts in (PISSARJEWSKY), A., ii, 595.
 between serum proteins and acids and alkalis (MOORE and BIGLAND), A., ii, 318.
 in the reaction between alcohol and sulphuric acid (KREMAN), A., ii, 700.
 $KHg_{2n} + Na \rightleftharpoons K + NaHg_n + (m-n)Hg$ (SMITS), A., ii, 401.
 of potassium chloride and sodium nitrate (UYEDA), A., ii, 336.
 $Ag + Ag^+ \rightleftharpoons Ag_2$ (JELLINEK), A., ii, 279.
 in the system, lead, cadmium and mercury (JÄNECKE), A., ii, 699.
 in the system, lead carbonate, potassium chromate, lead chromate, and potassium carbonate (GOLBLUM and STOFFELLA), A., ii, 698.
 of carbon monoxide with carbon dioxide and oxygen, effect of temperature on the (RHEAD and WHEELER), T., 2178; P., 220.
 Kinetics, chemical (SACKUR), A., ii, 113.
 of toxic action of dissolved substances (PAUL, BIRSTEIN, and REUSS), A., ii, 1098, 1099.
 of the formation of ethyl ether (KREMAN), A., ii, 945.
 of the reaction between bromine and formic acid in aqueous solution (BOGNAR), A., ii, 252.
 of the decomposition of quaternary ammonium salts in chloroform solution (WEDEKIND and PASCHKE), A., ii, 597.
 of the reaction between silver salts and aliphatic iodides (DONNAN and PORTS), T., 1882; P., 212.

AFFINITY, CHEMICAL:—
 Kinetics, of the killing of bacteria in oxygen (PAUL, BIRSTEIN, and REUSS), A., ii, 642.
 Reactivity and chemical constitution of halogen compounds, the relation between (CLARKE), T., 416; P., 26.
 Chemical action and ionisation (REBOUL), A., ii, 822.
 in mixtures of water with non-electrolytes, free energy of (PISSARJEWSKY and ZEMBISKY), A., ii, 595.
 in mixtures of glycerol and alcohols, free energy of (PISSARJEWSKY and TRACHONOTOWSKY), A., ii, 402.
 apparent, at a distance (LIESERMAN), A., ii, 703.
 Chemical reactions, organic, application of physico-chemical methods to determine the mechanism of (MICHAEL), A., i, 341.
 Equilibrium constant, influence of the solvent on the (PISSARJEWSKY and BREKOWSKY), A., ii, 595.
 Catalysis (HÖSEKEN), A., i, 152.
 by acids (DAWSON), P., 323.
 stereochemistry of (FAJANS), A., ii, 599.
 in heterogeneous systems (DENHAM), A., ii, 598.
 of aromatic acids (SENDERENS), A., i, 318.
 Catalytic action of weak acids in ester formation (GOLDSCHMIDT and UDRY), A., ii, 283.
 Catalytic hydrogenation of unsaturated organic compounds (FOURNIER), A., i, 92.
 of aromatic and quinoline bases (HARZEN), A., i, 63.
 Catalytic phenomena, theory of (ZAVRIEFF), A., ii, 284.
 Catalytic reactions in the wet way (SENDERENS), A., i, 649.
 by means of metallic oxides (MAILHE), A., i, 807.
 Catalytic reduction of the nitro-group by hydrogen sulphide (GOLDSCHMIDT and LARSEN), A., ii, 282.
 Dissociation, relation between band spectra and (KÖNIGSBERGER and KUPFERER), A., ii, 670.
 and density of aqueous salt solutions, relation between (TERESCHIN), A., ii, 190.
 Dissociation equilibria, heterogeneous, is mercurous chloride an exception to the theory of? (SMITH), A., ii, 272.

AFFINITY, CHEMICAL:—

Dissociating binary compound, heat and volume changes when the components of, are transferred separately into the gas space (RUEB), A., ii, 266.

Energy theory of isomerism (QUARTAROLI), A., ii, 491.

of the elements, and the part remaining in combinations (QUARTAROLI), A., ii, 491.

Enzyme action, kinetics of (HEDIN), A., i, 290.

Deviation of, from the unimolecular law (PIERCE), A., i, 907.

reversibility of (KOHLE; TAYLOR), A., i, 82.

Hydrolysis and reaction velocity in mixtures of alcohol and water (EULER and AFUGGLAS), A., ii, 25.

of salts of amphoteric electrolytes (BEVERIDGE), A., ii, 25.

of esters of halogen-substituted acids (DRUSHEL and HILL), A., ii, 702.

Velocity of addition of bromine to unsaturated compounds (SUNBOROVICH and THOMAS), T., 715.

Velocity of crystallisation, diminution of, by addition of foreign substances (KREINDLICH), A., ii, 1045.

Velocity of dissolution of salts (WAGNER), A., ii, 275.

Velocity of hydration of acid anhydrides (RIVETT and SIGGWICK), T., 1677; P., 200.

of acetic anhydride (RIVETT and SIGGWICK), T., 732; P., 66.

Velocity of hydrolysis of neutral salts (SENTER), A., ii, 276.

Velocity of chemical reaction, temperature-coefficient of (TRAUTZ), A., ii, 24, 114, 1051.

Velocity of reaction, influence of the medium on the (BIGARSKY), A., ii, 251; (SCHLOFF and FUDOKIN), A., ii, 402.

in a heterogeneous system (ESPIL), A., ii, 402.

calculation of, from current potential curves (EUCKEN), A., ii, 279.

measurement of, by means of viscosity (DUNSTAN), P., 226.

and admixture, new method of measurement of (BENEDICKS), A., ii, 280.

and Hydrolysis in mixtures of alcohol and water (EULER and AFUGGLAS), A., ii, 25.

of metals and dissolved halogens (VAN NAME and EDGAR), A., ii, 280.

AFFINITY, CHEMICAL:—

Velocity of reaction of ketones with iodine (DAWSON and WHEATLEY), T., 2048; P., 233.

Velocity of electrolytic oxidation, of organic acids (AGENO and DOKINI), A., i, 357.

Velocity of transformation of osmium bases, colour bases and cyanides into carbinol bases and leucocyanides (MÜLLER), A., i, 869.

Rate of extraction of plant nutrients from the phosphates of calcium and from loam soil (BELL), A., ii, 745.

Periodic reactions, theory of (LOIKA), A., ii, 401.

Agar-agar, crystallisation of (v. WELMAR), A., ii, 1046.

assimilation of nitrogen with, as source of energy (FRINGSHEIM and FRINGSHEIM), A., ii, 230.

Agglutinins, influence of temperature on the decomposition of (MADSEN and STRENG), A., ii, 319.

Agmatine (KOSSEL), A., i, 500, 635.

Air. See Atmospheric air.

Anga Ica (PONTI), A., ii, 63.

Alanyl-leucinamide hydrobromide (BERGELL and v. WÜLFING), A., i, 945.

d-Alanyl l-leucyl-l-isoleucine, and its copper salt (ARDERHALDEN and HIRSCH), A., i, 720.

l-Alanyls erine and its anhydride (FUCHER and ROESNER), A., i, 668.

Albumin from the blood-serum of the horse (MAXIMOWITSCH), A., i, 343.

action of organic bases and amphoteric electrolytes on (HINDOVSCH), A., i, 646.

denatured, coagulation of (MICHAELIS and RONA), A., i, 646.

solutions, the internal friction of (MICHAELIS and MOSTYSER), A., ii, 532; (PAULI and WAGNER), A., ii, 830; (MICHAELIS), A., ii, 1040.

detection and estimation of, in urine (OGREO), A., ii, 560; (ATRECHET), A., ii, 560, 663.

Alcaptonuria (RAVOLD and WARREN), A., ii, 733.

p-aminophenylalanine in (BLUM), A., ii, 733.

Alcohol. See Ethyl alcohol.

Alcohol, $C_6H_{13}O_6$ from the action of acetone on magnesium amalgam (RICHARD and LANGLANS), A., i, 439.

$C_6H_9O_6$ and its semicarbazone and benzoate (ZINCKE and ZAHN), A., i, 317.

$C_{10}H_{16}O$, from pinene hydrochloride (CHEMISCHE FABRIK AUF AEUßER VORM. E. SCHEERING), A., i, 369.

- Alcohol, $C_{10}H_{18}O_2$, and its monoacetyl derivative (DELFINE), A., i, 219.
- $C_{11}H_{18}O_8$, from methyl *o*-methoxytoluate and magnesium methyl iodide (GUILLAUMIN), A., i, 375.
- $C_{11}H_{18}O_8$, from 3-methoxymethyl-*p*-toluic acid and magnesium methyl iodide (GUILLAUMIN), A., i, 375.
- $C_{11}H_{18}O_8$, from 1-methyl-4-isopropyl-3-allylcyclohexan-3-ol (RYSCHENKO), A., i, 181.
- $C_8H_2O_4$, from rhizome of *Cimicifuga racemosa* (FINNEMORE), A., ii, 801.
- $C_{22}H_{32}O_{12}N$, from the aldehydic ester $C_{22}H_{32}O_{12}N$ (LEUCHS and THEODOR-ESCU), A., i, 396.
- Alcohols**, chemical constitution and physiological action of (LORR), A., ii, 147.
- specific inductivity capacity of (BRILLARD), A., ii, 680.
- decomposition of, by ultra-violet light (BERTHELOT and GAUDECHON), A., ii, 814.
- action of metallic oxides on (SABATIER and MAILHE), A., i, 294.
- preparation of thiols from, by catalysis (SABATIER and MAILHE), A., i, 456.
- mixture of glycerol and free energy of chemical action in (PISSARJEVSKY and TRACHONOTOWSKY), A., ii, 402.
- aliphatic, relation between the structure of, and the rate of esterification (MICHAEL), A., ii, 195.
- aminoaryl (EMDE and RUNNE), A., i, 479.
- aromatic, action of hypophosphorous acid on (FOSSE), A., i, 292.
- aromatic, preparation of, and their acetates (WOHL and BERTHOLD), A., i, 619.
- hydroaromatic, conversion of, into the corresponding phenols (BRUNEL), A., i, 479.
- polyhydric, phosphoric acid esters of (CONARD), A., i, 609.
- primary, action of metallic oxides on (SABATIER and MAILHE), A., i, 608.
- secondary, condensation of, with their sodium derivatives (GUERRET), A., i, 454.
- secondary, of the fatty series, rotations of (PICKARD and KENYON), P., 336.
- detection of traces of (DE STOECKLIN), A., ii, 162.
- See also Amino-alcohols.
- alcoholic liquids, estimation of butyl and amyl alcohols in (LASSERRE), A., i, 1005.
- Alcoholometry**, reduced (DE SAPORTA), A., ii, 356.
- Alcohol-oxydase** (BATELLI and STERN), A., ii, 980.
- Aldazines**, interaction of magnesium alkyl halides and (BUSCH and FLEISCHMANN), A., i, 282.
- Aldebaranium**, arc spectrum of (EDER and VALENTA), A., ii, 561.
- Aldehydease** in animal tissues (BATELLI and STERN), A., ii, 1085.
- Aldehyde**, $C_{11}H_{14}O_8$, from 2-methoxy-1-methyl-3-*p*-allylbenzene (GUILLAUMIN), A., i, 478.
- C_2H_5ON , and its oxime and phenylhydrazones (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 428.
- C_3H_7ON (thure) (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 428.
- Aldehydes**, action of, on hydrocarbons under the influence of sunlight (PATERNÒ and CHIEFFI), A., i, 41.
- decomposition of, by ultra-violet light (BERTHELOT and GAUDECHON), A., ii, 814.
- addition of anhydrides to (WENSCHEIDER and SPATH), A., i, 155.
- condensation of, with ketones, and formation of pyridine derivatives from the condensation products (SCHOLTZ and MEYER), A., i, 561.
- transformation of, Camizzaro's acceleration of, by enzymes (PARNAS), A., ii, 980.
- carbon monoxide from (BISTRZYCKI and FELLMANN), A., i, 321.
- diacetates of, influence of orthosubstituents on the formation of (SPATH), A., i, 488.
- aromatic, condensation of arylsulphonated acetonitriles with (TRÖGER and BREMER), A., i, 113.
- condensation of *m*-aminodimethyl- and diethylaniline with (MOORE), A., i, 280.
- racemic. See Racemic aldehydes.
- and ketones, Bittor's reaction for (REITZENSTEIN and STAMM), A., ii, 358.
- determination of, in distilled liquors (VIVENCIO DEL ROSARIO), A., ii, 760.
- estimation of, in alcohol (RONNET), A., ii, 663.
- Aldehyde-cyanohydrins**, preparation of acyl derivatives of (DAVIS), T., 949; P., 89.
- Aldehydemutase** (PARNAS), A., ii, 980.
- Aldehyde resins**, production of, by the carbonisation of wood (DUCHEMIN), A., i, 462.

- o*-Aldehydobenzyl-1-hydrindone**, 2-*o*-hydroxy- (THIELE and WANSCHEIDT), A., i, 831.
- p*-Aldehydo-*o*-cresotic acid** (FARBEN-FABRIKEN VORM. F. BAYER & CO.), A., i, 321.
- o*-Aldehydo-*p*-cresotic acid** (FARBEN-FABRIKEN VORM. F. BAYER & CO.), A., i, 321.
- 4-Aldehydophenyl sulphide**, 2-nitro- (nitrobenzaldehyde sulphide) (KRÄNZLEIN), A., i, 390.
- 2-*o*-Aldehydophenyl-3-indone**, and its dibromide (THIELE and WEITZ), A., i, 855.
- o*-Aldehydosalicylic acid**, *p*-chloro- (FARBENFABRIKEN VORM. F. BAYER & CO.), A., i, 321.
- 3-Aldehydotriphenylacetic acid**, 4-hydroxy- (BISTRZYCKI and FELLMANN), A., i, 321.
- 3-Aldehydotriphenylcarbinol**, 4-hydroxy- (BISTRZYCKI and FELLMANN), A., i, 321.
- Aldoses** distinguished from ketoses by means of bromine water (VOTOČEK and NEMČEK), A., ii, 463.
- Alexandrite**, colour of (HAUSER), A., ii, 873.
- Algae**, action of arsenates on the growth of (COMÈRE), A., ii, 437.
- Aliphatic compounds**, new synthesis of aromatic compounds from (KOMNENOS), A., i, 362.
- Alkali bromides**, electrolysis of, and retardation of the anodic separation of the halogens (FOERSTER and YAMASAKI), A., ii, 576.
- halogen salts**, conversion of halogen into (MESCHORER), A., ii, 410.
- hydrogen carbonates** (DE FORCRAND), A., ii, 124.
- chlorides**, alloys of the (SCHEMTSCHEUSCHNY and RANBACH), A., ii, 204.
- formates**, reducing action of (VOURNASOS), A., ii, 549.
- hydroxides**, equilibrium curves of binary systems of the (v. HEVENY), A., ii, 835.
- metals**, photoelectric behaviour of, in polarised light (POHL), A., ii, 90.
- photoelectric sensitiveness of the** (POHL and PRINGSHEIM), A., ii, 379, 472.
- absorption spectra of vapours of** (BEVAN), A., ii, 370.
- electrical resistance of the** (HACKSPILL), A., ii, 821.
- production of negative electrons during the reaction of gases on** (HABER and JUST), A., ii, 572.
- Alkali**, emission of electric charges by (DUNOTER), A., ii, 253.
- the colour films formed on the by electric discharges** (ELSTER and GEITEL), A., ii, 1031.
- mercury alloys with** (SMITH and BENNETT), A., ii, 500.
- coloured hydrides of, and their photoelectric sensitiveness** (ELSTER and GEITEL), A., ii, 379.
- manganil-manganates of the** (ATCHEL), A., ii, 298.
- nitrites**, action of, on the insoluble carbonates (OECHSNER DE CONINCK), A., ii, 411.
- sulphates**, solubility of, in alkaline solutions (D'ANS and SCHREINER), A., ii, 848.
- sulphates and calcium sulphate**, binary systems formed from the (MILLER), A., ii, 776.
- Alkalies**, spectra of the (HICKS), A., ii, 88.
- estimation of, in silicates** (DÖRNER), A., ii, 348.
- removal of ammonium salts in estimation of the** (JAMNOR), A., ii, 1111.
- Alkali content of potable and mineral waters**, estimation of the (COMAN-DUCCI), A., ii, 1111.
- Alkaline earth carbonates**, action of ammonium salts on (SELVAKU), A., ii, 209.
- iodides dissolved in pyridine**, electrolysis of (v. HEVENY), A., ii, 928.
- metals**, mercury alloys with (SMITH and BENNETT), A., ii, 500.
- estimation and separation of** (DETTON and MOROIT), A., ii, 843.
- the use of phenol in the estimation of** (LINDER and BRASARY), A., ii, 548.
- Alkaline earths**, restoration of phosphorescence to sulphides of the (GERNET), A., ii, 173.
- Alkaloid**, $C_{22}H_{33}O_3N$, from *Corydalis cora*, and its hydrobromide (GIESSEL), A., i, 501.
- Alkaloid, or Alkaloids**, from angustura See Angostura.
- from cinchona**. See Cinchona.
- corydalis**. See also Corydalis.
- from curare**, halogen derivatives of (BTRACZEWSKI and ZUBJEWSKI), A., i, 872.
- from Duboisia hopwoodii** (BOZGA), A., ii, 993.
- from ergot** (BARGER and EWING), I, 284; P., 2.
- from seeds of *Lunarca hirs.*** (HAIRS), A., ii, 234.
- formation and distribution of, in *Papaver somniferum*** (KREBS), A., ii, 1101.

- Alkaloid, or Alkaloids, from the bark of**
Pseudorinchona africana, hydrolysis of (FOURNEAU), A., i, 501.
 from the *Pukatea* (ASTON), T., 1381; P., 11.
 from roots of *Sanguinaria canadensis* (FÖRSTENSKI), A., i, 874.
 from *Solanacea*, influence of cultivation on (CHEVALIER), A., ii, 285.
 from strychnos. See Strychnos.
 constitution of (PERKIN and ROBINSON), T., 365; P., 24.
 action of chlorine on (BURACZEWSKI and ZHURAWSKI), A., ii, 873.
 migration of, in grafting (JAVILLIER), A., ii, 646.
 and their salts, specific rotatory power of (CARR and REYNOLDS), T., 1328; P., 180.
 aromatic nitro-derivatives as precipitants for (ROSENTHALER and GÖRNEU), A., ii, 557.
 reactions of, with hydrogen peroxide (SHAER), A., ii, 910.
 estimation of, by titration of salts of, with alkalis (RUNNE), A., ii, 362.
 by the Volhard method (ELVOVE), A., ii, 361.
aryl sodium carbonates (FRANCHIMONT), A., i, 4.
xylamines as products in the Kjeldahl digestion (REDMANS), A., ii, 1018.
xyaminotoluole acids, synthesis of (HÖRNER, SCHOTTMÜLLER, and FREUND), A., i, 84.
aryl groups, interchange of, in acid esters (KOMNENOS), A., i, 361, 541; (FRANGL), A., i, 480.
 displacement of, under the influence of aluminium chloride (DUVAL), A., i, 684.
ylene group, relative addition in the Baeyer and Probeck), A., i, 805.
xylinitroamines (FRANCHIMONT), A., 618.
xylyphenazothionium, derivatives of (BARNETT and SMILES), T., 980; A., 92.
xylypyrrolidines, new preparation of (GÖFFLER), A., i, 632.
antoin, the occurrence and importance of, in human urine (SCHITTENHELM and WIENER), A., ii, 52.
 essence of, in the seeds of *Datura Metel* (DE PLATO), A., ii, 742.
 ethylation and constitution of (BIELTZ), A., i, 594.
 chemical activity of (MENDEL and MAKIN), A., i, 286.
 influence of, on the nitrogen metabolism of rabbits (SCHITTENHELM and SEISSER), A., ii, 423.
- Allantoin**, excretion of, influence of ingestion of nucleic acid on the (HIROKAWA), A., ii, 787.
 recognition and stability of, and its content in human urine (WIECHOWSKI), A., ii, 634.
 presence and detection of, in human urine (ASCHER), A., ii, 793.
 estimation of, in urine (LANDSAY), A., ii, 83.
 imino-, physiological behaviour of (SAIKI), A., ii, 432.
Allenecarboxylic acids, substituted, experiments on (LAPWORTH and WECHSLER), T., 38.
Alliin (SCHIMMEL & Co.), A., i, 757.
Allisin (SCHIMMEL & Co.), A., i, 757.
Allophane, action of acetic acid on (VAN DER LEEDE), A., ii, 621.
Allotropic modifications, atomic volume of (COHEN and OLIE), A., ii, 102.
Allotropy and internal equilibrium (SMITS), A., ii, 195, 400.
Alloxan, instability of (WHEELER; ROBERT), A., i, 468.
 condensation products of (KÄPPLING), A., i, 780.
Alloys, formation of, by pressure (SPRING), A., ii, 126.
 solubility of gases in (SIEVERTS and KREMEHAAR), A., ii, 410.
 magnetisation of, as a function of the composition and the temperature (HONDA), A., ii, 686.
 thermoelectricity of (REDOLEI), A., ii, 575.
 electrical conductivity of, and their temperature coefficients (GUERTLER), A., ii, 570.
 and metals, contraction of, during cooling (WÜST), A., ii, 260.
 liquid, electrical conductivity of (BORNMANN and MÜLLER), A., ii, 924.
 metallic, specific heat of (SAPOSHNIKOFF), A., ii, 182.
 variation of the physical properties of (PANNAIN), A., ii, 829.
 thermoelectric properties of (HAKEN), A., ii, 367.
Allylembinol, ethyl ether and its dibromo-derivative and diphenylurethane (PARISELLE), A., i, 353.
Allyldihydroisindole, and its picrate (v. BRAUN), A., i, 506.
N-Allylglycine, ethylester (ALPERN and WEIZMANN), P., 345.
o- and p-Allyloxybenzoic acid, menthyl esters of (COHEN and DUDLEY), T., 1745.
Allylthiocarbamic acid, methyl and bornyl esters (ROCHDESTVENSKY), A., i, 107.

- Allylthiocarbamide**, oxidation of (BARNETT), T., 65.
- ψ -**Allyl-m** and *p*-**tolylxyacetic acid** (GUILLAUMIN), A., i, 477.
- Allylurethane** and its nitroso-derivative (NIRDLINGER, ACKER, and HEAPS), A., i, 342.
- Aloin** (OESTERLE and RIAT), A., i, 274.
- Aloinose**, from aloin (LEGER), A., i, 463.
- identity of, with *d*-arabinose (LEGER), A., i, 543.
- Alstonite** (KREUTZ), A., ii, 306; (SPENCER), A., ii, 307.
- Alum**, formation of basic aluminium sulphate when zinc sulphate is boiled with (SCHWEISSINGER), A., ii, 615.
- storage of, in zinc vessels (LANGKOPF), A., ii, 507.
- Alumina**. See Aluminium oxide.
- Aluminium**, preparation of, from aluminium silicate (GRÖPFEL), A., ii, 289.
- as a laboratory experiment (NEUMANN and OLSEN), A., ii, 412.
- band spectrum of (LENOX DE BOIS-BAUDMAN), A., ii, 3.
- ultra-red line spectrum of (PASCHEN), A., ii, 1014.
- action of heat on, in a vacuum (KOH-ABREST), A., ii, 212.
- action of mercuric chloride on (KOH-ABREST), A., ii, 506.
- cation, hydrolysis of salts of the (POVARIN), A., ii, 412.
- dishes and other appliances in electrolytic analysis (FORMANEK and PEČ), A., ii, 67.
- Aluminium alloys** with copper, electrical properties of (BRONIEWSKI), A., ii, 128.
- with mercury, oxidation of (JOURDAIN), A., ii, 715.
- with silver, electrical properties of (BRONIEWSKI), A., ii, 715.
- Aluminium salts**, formulæ of, and of corresponding compounds of other metals (COOPS), A., ii, 506; (OLIVIER), A., ii, 507.
- influence of, on the colour of flowers (VOCK), A., ii, 62.
- volumetric estimation of (TELLE), A., ii, 457.
- Aluminium sodium carbonate**, dawsonite, an (GRAMAM), A., ii, 136.
- chloride, compounds of, with nitro-compounds of benzene hydrocarbons (MENSCHUTKIN), A., i, 234.
- nitride, preparation and fusion of (WOLKE), A., ii, 854.
- nitrides (KOH-ABREST), A., ii, 506.
- Aluminium nitrides and oxides**, from heating the metal in air (SERPEL), A., ii, 615; (KOH-ABREST), A., i, 715.
- oxide (*alumina*), thermic reduction of (ASKENASY and LEBEDEF, A., ii, 780).
- from oxidation of aluminium amalgam in air (JOURDAIN), A., ii, 297.
- adsorption of metals and metallic oxides by (KLEINSTUCK), A., ii, 715.
- oxides (KOH-ABREST), A., ii, 506.
- phosphate, positive electrification due to heating (GARRETT), A., ii, 923.
- silicate, preparation of metallic aluminium from (GRÖPFEL), A., ii, 289.
- silicates, isomerism in the group of (VERNADESKY), A., ii, 136.
- sulphate, use of, in catalytic reactions (SENDERENS), A., i, 649.
- Aluminium organic compounds**, preparation of (SCHLIEMANN'S EXPORT-CEKRESIN-FABRIK), A., i, 651.
- Aluminium**, estimation of, in its ores (CALAFAT Y LEÓN), A., ii, 1113.
- determination of, in inorganic plant constituents (HARR), A., ii, 1001.
- Alums**, diffusion of the (PARSONS and EVANS), A., ii, 1069.
- Amalgams**. See Mercury alloys.
- Amblygonite**, analysis of (COMTE-BOUFF), A., ii, 897.
- Amide**, $C_9H_9O_2NBr$, from aminodimethylcarbinol and bromoacetyl chloride (FOURNEAU), A., i, 829.
- $C_{22}H_{13}O_3NS$, from 1-aminoanthraquinone and anthraquinone-2-sulphonyl chloride (SEER and WEITZENBÖCK), A., i, 571.
- $C_{22}H_{13}O_3N$, from 2-aminoanthraquinone (SEER and WEITZENBÖCK), A., i, 570.
- $C_{42}H_{22}O_{10}N_2S_2$, from 1:5-diaminoanthraquinone and anthraquinone-2-sulphonyl chloride (SEER and WEITZENBÖCK), A., i, 571.
- Amides**, preparation of, by the action of ammonium sulphide on aliphatic aromatic ketones (WILLEBRODT and SCHOLTZ), A., i, 392.
- from phenyl alkyl ketones (WILGERODT and HAMBRECHT), A., i, 117.
- viscosity of (DUNSTAN and MURRELL), T., 1935; P., 201.
- molecular complexity of, in various solvents (MELDRUM and TINSLEY), T., 1905; P., 211, 213.

- Amides**, the molecular complexity of, in the liquid state (TURNER and MERRY), P., 128.
 of amino-acids (BERGELL and v. WELFING), A., i, 304.
 of sulphuric acid (EPHRAIM and GUREWITSCH), A., ii, 198.
Amidines, constitution of the (COHEN and MARSHALL), T., 328; P., 24.
Amido-oximes (RUSSELL), T., 953; P., 89.
Amines (JOHNSON and GUEST), A., i, 310, 470.
 structure and sympathomimetic action of (BARGER and DALE), A., ii, 981.
 molecular complexity of, in the liquid state (TURNER and MERRY), P., 128.
 action of, on phthalic acid (TINGLE and BRENTON), A., i, 263; (TINGLE and BATES), A., i, 849.
 condensation of, with aromatic ketones (REDDELLEN), A., i, 746.
 aromatic, coloured additive products of (WIELAND and WECKER), A., i, 242.
 additive compounds of, with phenols (DOLLINGER), A., i, 700.
 action of, on ethyl malonate (CHARTAWAY and OLMSTED), T., 938; P., 69.
 primary aromatic, condensation of, with chloralaniline (JORDAN), A., i, 664.
 mercuriated, action of dinitrophenyl-pyridinium chloride on (REITZENSTEIN and STAMM), A., i, 348.
 primary, action of, on glyoximeperoxides (BÖSEKEN), A., i, 648.
 primary and secondary, new method of preparation of, from ketones (LÖFFLER), A., i, 611.
 and ammonia, separation of (BERTHEAUME), A., ii, 663, 808.
 salts of, reaction with rongalite (BINZ and MARX), A., i, 723.
 secondary, preparation of, from carb-oxylic acids (LE SUEUR), T., 2433; P., 290.
 condensation of, with ethyl- γ -bromo- α -dimethylacetoacetate (GAULT and THIRODE), A., i, 356.
Amino-acids, production of sugar from (RINGER and LUSK), A., ii, 227.
 quantity of, yielded by acid hydrolysis of proteins (OSBORNE and BREESE), A., i, 447.
 catalytic action of (DAKIN), A., i, 101.
 degradation of, by bacteria (BRASCH), A., ii, 60.
Amino-acids, utilisation of, by the tubercle bacillus (KOELKER and HAMMER), A., ii, 737.
 fate of, in the organism (LUSK), A., ii, 520.
 katabolism of (FLATOW), A., ii, 321.
 insoluble lead salts of (LEVEENE and VAN SLUYKE), A., i, 719.
 derivatives of (ABDERHALDEN and GUGGENHEIM; ABDERHALDEN and FENK), A., i, 226; (ABDERHALDEN and KAUTZSCH), A., i, 253; (ABDERHALDEN and BLUMBERG), A., i, 371.
 compounds of, with ammonia (BERGELL and v. WELFING), A., i, 365; (BERGELL and BRÜGGSCH), A., i, 546.
 attempts to prepare glycerides of (ALPERN and WEIZMANN), P., 345.
 methylation of (ENGELAND), A., i, 843.
 amides of (BERGELL and v. WELFING), A., i, 304.
 esters of, compounds of quinones with (FISCHER and SCHRADER), A., i, 270.
 action of *p*-benzoquinone on (SIEGMUND), A., i, 749.
 halogen (WHEELER and JOHNS), A., i, 114.
 aromatic, synthesis of (HOUBEN, SCHOTTMÜLLER and FREUND), A., i, 34; (HOFREX and FREUND), A., i, 110.
 alkylation of (WHEELER and JOHNS), A., i, 381, 842; (WHEELER and HOFFMAN), A., i, 666.
 racemic, hydrolysis of, by fungi (PRINGSHEIM), A., ii, 437.
 in urine, formaldehyde-titration of (MALFATTI), A., ii, 662.
 estimation of, by the formaldehyde titration (HENRIQUES and SØRENSEN), A., ii, 466; (DE JAGER), A., ii, 467.
 estimation of, by formaldehyde, influence of urea on the (DE JAGER), A., ii, 761.
 estimation of, in urine (LINDSAY), A., ii, 83; (FREY and GIGON; HENRIQUES and SØRENSEN; YOSHIDA), A., ii, 164.
Amino-alcohols, derivatives of (FOURNEAU), A., i, 245, 822.
Amino-aldehydes, preparation of (CHEMISCHE WERKE VORM. HEINRICH BYE), A., i, 322.
Aminoaryl alcohols. See Alcohols, aminoaryl-
Amino-compounds, aliphatic, action of oxygen on, in the presence of copper (TRAUBE), A., i, 294.

- Amino compounds, aromatic, action of sulphites on** (BUCHERER and SONNENBURG), A., i, 144.
- Aminohydroxy-acids, synthesis of** (FISCHER and ZEMPLÉN), A., i, 100.
- Amino-ketones** (GABRIEL), A., i, 229.
- Aminolactones from diacetone alcohol** (KOHN and BUM), A., i, 136.
- p-Aminophenols, action of unsaturated dicarboxylic acids on** (PIUTTI), A., i, 264.
- Ammonio-salts, new series of solid** (POMA), A., ii, 417.
- Ammonia formation in soils** (LIPMAN and BROWN), A., ii, 435.
- gaseous, specific heat and chemical equilibrium of** (NERNST), A., ii, 265.
- combustion of, effect of ultra-violet light on the** (BERTHELOT and GAUDECHON), A., ii, 564.
- the elimination of, following the administration of amino-acids, glycylglycine, and its anhydride** (LEVENE and MEYER), A., ii, 53.
- concentration of, in blood, to produce tetany** (JACOBSON), A., ii, 986.
- solid hydrates of** (RUPERT), A., ii, 505.
- action of, on mercurous chloride** (SAHA and CHONDHURI), A., ii, 712.
- quantitative distillation of, by aeration** (KOEFER), A., ii, 651.
- and amines, separation of** (BERTHELOT), A., ii, 663, 808.
- source of error in the estimation of** (BARRAL), A., ii, 155.
- a new distillation arrangement for estimation of** (BERTHOLD), A., ii, 70.
- estimation of, by Ronchèse's method** (WILKIE), A., ii, 240.
- estimation of very small amounts of, in large quantities of air** (LIECHTI and RITTER), A., ii, 70.
- estimation of, in blood** (WOLF and MARRIOT), A., ii, 762.
- estimation of, in water, in the presence of hydrogen sulphide** (BARTOW and HARRISON), A., ii, 998.
- titration of, in urine** (v. SPINDLER), A., ii, 449; (BJÖRN-ANDERSEN and LAURITZEN), A., ii, 450.
- Ammonium salts of volatile acids, hydrolysis of** (BICH), A., ii, 291.
- quaternary, kinetics of the decomposition of, in chloroform solution** (WEDEKIND and PASCHKE), A., ii, 597.
- quaternary, influence of constitution on the velocity of decomposition of** (WEDEKIND and PASCHKE), A., i, 372.
- Ammonium ferric arsenate** (FERNANDEZ), A., ii, 509.
- antimony tetrabromide and ferric chloride** (EPHRAIM and WEINBERG), A., ii, 41.
- carbonate, electrolytic oxidation of** (FICHTER and KAPPELER), A., ii, 93.
- scandium carbonate** (MEYER, WINTER, and SPETER), A., ii, 854.
- perchlorate as a reagent** (SALVADORI), A., ii, 1002.
- chloride, vapour pressures of** (SMITH and MENZIES), A., ii, 1037.
- reaction of, with potassium dichromate** (FRANKFORTER, ROEBRICH, and MANUEL), A., ii, 292.
- antimony ferric chloride** (EPHRAIM and WEINBERG), A., ii, 41.
- halides, dimorphism of** (WALLACE), A., ii, 208.
- hydrogen fluoride, evaluation of** (DEUSSEX), A., ii, 749.
- zinc iodide** (EPHRAIM and MODEL), A., ii, 851.
- barium arsenosomolybdate** (EPHRAIM and FEIDEL), A., ii, 301.
- cupric arsenosomolybdates** (EPHRAIM and FEIDEL), A., ii, 301.
- phosphomolybdate, precipitation of, in the presence of organic acids** (MADERNA), A., ii, 804.
- silver nitrate** (SCHREINEMAKERS and DE BAAT), A., ii, 489.
- nitrite, preparation of** (NEOGI and ADHICARY), P., 297.
- magnesium phosphate** (BUBE), A., ii, 804.
- oxytriselenophosphate** (EPHRAIM and MAJLER), A., ii, 207.
- sulphate, sulphuric acid and water at 30°, the system** (VAN DOLF), A., ii, 698.
- efficiency of, as a fertiliser** (VASNA), A., ii, 538.
- magnesium sulphate, solubility of** (LOTHIAN), A., ii, 504.
- thiocyanate, cryohydrate of** (VASTLIEFF), A., i, 465.
- Amorphous substances, transformation of, into crystalline** (DOELTER), A., ii, 696, 834.
- Amygdalase, occurrence of, in plants** (ARMSTRONG, ARMSTRONG, and HORTON), P., 334.
- Amygdalin, decomposition of** (FEIST), A., i, 123.
- hydrolysis of, by emulsin** (ROSENTHALER), A., i, 403.
- a biase derived from** (GIAJA), A., i, 800.
- Amyl alcohol, a reaction of** (v. WYSS HERZFELD, and REWINZOFF), A., ii, 462.

- Amyl alcohol**, estimation of, in alcoholic liquids (LASSERRE), A., ii, 1005.
- Amylamine**, ferrichloride (SCHOLTZ), A., i, 96.
- δ -chloro-**, hydrochloride and platinichloride (V. BRAUN), A., i, 820.
- Amylase** (WOHL and GLIMM), A., i, 799, from cereals and malt (CHRSZCZCZ), A., ii, 994.
- Amylases** (KENDALL and SHERMAN), A., i, 799; (SHERMAN, KENDALL, and CLARK), A., ii, 1012.
- Amylbenzene**, ϵ -chloro-, and ϵ -iodo- (V. BRAUN), A., i, 844.
- 6-Amylcarbamino- α -naphthol 3-sulphonic acid**, sodium salt (BADISCHE ANILIN- & SODA-FABRIK), A., i, 667.
- Amylene**, action of aluminium chloride and of heat on (ENGLER and ROUTALA), A., i, 2.
- β -Amylene**, additive power of (BRUNEL and PROBECK), A., i, 805.
- 2-Amylenedihydroisindole**, and its methiodide (SCHOLTZ and WOLFRUM), A., i, 773.
- α , β -**, and *p*-**isoAmyloxybenzoic acid**, methylesters of (COHEN and DUDLEY), T., 1744.
- Aer oxydase** in milk (BORDAS and TOUPLAIN), A., ii, 57; (SANTHOU), A., ii, 57, 226.
- Anæsthetic properties** of magnesium salts (GUTHRIE and RYAN), A., ii, 793.
- Anæsthetics** (BRITISH ASSOCIATION REPORTS), A., ii, 735.
- local, and narcotics (GROS), A., ii, 529, 793.
- and laurel leaves (WALLER), A., ii, 741.
- Analysis**, heat of chemical reactions as a basis for (HOWARD), A., ii, 239.
- spectral quantitative (HEMPEL and VON KLEMPERER), A., ii, 995.
- of anthracene derivatives (HOLDERMAN and SCHOLL), A., i, 285.
- of gases from mineral springs (HINTZ and GRÖNHUT), A., ii, 856, 1111; (HENRICH), A., ii, 1111.
- calorimetric, of hydrated salts (DONNAN and HOPE), A., ii, 392.
- Analysis**, electro- (BRITISH ASSOCIATION REPORTS), A., ii, 754; (BENNER), A., ii, 999; (KOLLOCK and SMITH), A., ii, 1000.
- rapid (PRICE and HUMPHREYS), A., ii, 446.
- rapid, the mercury cathode in (KIMLEY), A., ii, 654.
- of metals (PERKIN and HUGHES), A., ii, 898.
- elementary, of difficultly combustible substances rich in carbon (HOLDERMAN and SCHOLL), A., ii, 353.
- Analysis** by means of a calorimetric bomb (HIGGINS and JOHNSON), A., ii, 460.
- microchemical (EMICH and DONAU), A., ii, 152; (EMICH), A., ii, 237.
- of rare earths (URBAIN), A., ii, 505.
- qualitative, of the filtrate from the hydrogen sulphide group (PETERSEN), A., ii, 654.
- thermal, in metallurgical processes (FRIEDRICH), A., ii, 267.
- of fused mixtures of potassium sulphate and fluoride (KARANDÉEFF), A., ii, 33.
- application of, to binary organic systems (TSAKALOTOS and GUYE), A., ii, 826.
- application of, to organic chemistry (GUYE), A., ii, 470.
- volumetric, estimation of the alkaline-earth metals (DUROU and MOJOIT), A., ii, 343.
- by precipitation and measurement of electrical conductivity (DUROU), A., ii, 342.
- Anaphylaxis** of guinea-pigs, action of atropine on (AUER), A., ii, 985.
- Anglesite**, synthesis of (TIOU), A., ii, 621.
- Angostura alkaloids** (TRÜGER and MÜLLER), A., i, 414.
- Anhydride**, $C_{12}H_{10}O_2S_2$, from disulphide $C_{12}H_{10}O_2S_4$ and potassium cyanide (TSCHUGAEFF), A., i, 862.
- Anhydrides**, addition of, to aldehydes and ketones (WEGSCHEIDER and SPÄTH), A., i, 155.
- action of carbon tetrachloride vapour on (CAMBOLIVES), A., ii, 202.
- acid, rate of hydration of (RIVERT and SIDGWICK), T., 1677; P., 200.
- of monobasic acids, action of ethyl bromoacetate on (LUNIAK), A., i, 90.
- of fatty acids, preparation of, from their salts (GOLDSCHMIDT), A., i, 650.
- Anhydrocotarnineaminophthalide** (HOPE and ROBINSON), P., 230.
- Anhydrocotarnineitrophthalide** (HOPE and ROBINSON), P., 230.
- Anhydrodiresorcinolacacenaphthenone** (ZUFFA), A., i, 862.
- Anhydromethylenecitric acid**, and its sodium salt ("*citarine*") and its hexamethylenetetramine derivative ("*acimitol*"), assay of (HEGLAND), A., ii, 555.
- Anhydro-oxymethylenediphosphoric acid**, synthesis of (CONTARDI), A., i, 157.

- Anhydriporotin**, and its salts (HORMANN), A., i, 577.
- Anhydriporotinic acid** (HORMANN), A., i, 577.
- Anilides** and their chlorides, action of magnesium alkyl halides on (BUSCH and FLEISCHMANN), A., i, 728.
- Anilide-*o*-carboxylic acid**, cyano-, ethyl ester, and its hydrochloride and hydriodide (FINGER and ZEN), A., i, 382.
- Aniline**, and its homologues, absorption spectra of (PURVIS), T., 1546; P., 194.
- electrical conductivity of solutions in (SACHANOFF), A., ii, 1027.
- oxidation of (WILLSTÄTTER and MAJIMA), A., i, 748.
- reduction of nitrobenzene to (OTIN), A., i, 727.
- cause of the red coloration of (GIBBS), A., i, 550.
- existence of compound of phenol and, in the liquid state (KREMANN), A., ii, 581.
- action of dichloroacetic acid on, and its homologues (HELLER and ASCHKENAST), A., i, 738.
- additive compounds of, with bromo-nitrophenols (VAN ERP), A., i, 318.
- Aniline salts**, hydrolysis of, measured colorimetrically (TIZARD), T., 2490; P., 225.
- hydrochloride, molecular weight of (PRZYLUCKA), A., i, 106.
- antimonyl tartrate (YVON), A., i, 163.
- arsenyl tartrate (YVON), A., i, 310.

- Anophorite**, a new hornblende from the Katzenbuckel (FREUDENBERG), A., ii, 721.
- Anoxybiosis**, gaseous metabolism in (LESSER), A., ii, 429.
- Anthracene**, photoelectric experiments with (BYK and BORCK), A., ii, 814; (STUEBING), A., ii, 1021. derivatives, analysis of (HOLDERMANN and SCHOLL), A., i, 285. series, preparation of condensation products in the (BADISCHE ANILIN- & SODA-FABRIK), A., i, 397, 701, 702.
- Anthracene**, *dibromo-*, *tetrabromide*, reaction of, with organic magnesium compounds (NAUMOFF), A., i, 549.
- 1-Anthracenealdehyde**, 2-hydroxy-, and its oxime, phenylhydrazone and aldehyde (BRZDZIK and FRIEDLÄNDER), A., i, 190.
- Anthradipyrimidine** (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 445.
- Anthranil** (BAMBERGER), A., i, 277. and 2-anthranilcarboxylic acid, relation between (BAMBERGER and LINDBERG), A., i, 189.
- 2-Anthranilcarboxylic acid**. See Anthroxanic acid.
- Anthranilic acid** (*o-aminobenzoic acid*), condensation of, with aromatic aldehydes (WOLF), A., i, 735. 5-bromo-, its silver salt and ethyl ester (WHEELER and OATES), A., i, 481. 3:5-*dibromo-*, methyl ester and acetyl derivative (FREUNDLER), A., i, 138. chloro-, esters, condensation of, with nitrosobenzene (FREUNDLER), A., i, 445. 3:4- and 5:6-*dichloro-* (BADISCHE ANILIN- & SODA-FABRIK), A., i, 319. *tetrachloro-*, and its calcium and barium salts (BADISCHE ANILIN- & SODA-FABRIK), A., i, 382.
- Anthranilodiacetic acid** (BADISCHE ANILIN- & SODA-FABRIK), A., i, 318. 5:6-*dichloro-* (BADISCHE ANILIN- & SODA-FABRIK), A., i, 319.
- Anthranilodi- α -acetonitrile**, 5:6-*dichloro-* (BADISCHE ANILIN- & SODA-FABRIK), A., i, 319.
- Anthranol-1:8 disulphonic acid**, potassium salt (LIEBERMANN and ZSUFFA), A., i, 376.
- Anthranolsulphonic acid**, 1:2:6 and 1:2:7-trihydroxy-, sodium and barium salts (LIEBERMANN and ZSUFFA), A., i, 376.
- Anthranol-1-sulphonic acid**, potassium salt (LIEBERMANN and ZSUFFA), A., i, 376.
- Anthranol-3-sulphonic acid**, 1:2-*dihydroxy-* and its sodium salt (LIEBERMANN and ZSUFFA), A., i, 376.
- 1-Anthrapyrimidine**, 4-amino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 445.
- 1-Anthrapyrimidone** (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 445.
- Anthraquinone**, ethyl ether and naphthalene, critical phenomena of the system (PRINS), A., ii, 1050. derivatives, preparation of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 396. colour and affinity for mordants of (HILLER and GRUNTHAL), A., i, 859. preparation of sulphur derivatives of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 325. thioglycine derivatives of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 49.
- Anthraquinone**, amino-, action of benzyl chloride and of monochloroacetic acid on (SEER and WEITZENBACH), A., i, 571. chloro- α - and β -amino-, acetyl derivatives of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 750. 1:4-*dichloro-*, 1:4-*dichloro-5-amino-*, its acetate and acetyl derivative, and 1:4-*dichloro-5-nitro-* (WALSH and WREZMANN), T., 687; P., 61. chloroacetyl-1-amino-, 1-amino-4-hydroxy-, 1:4-diamino-, 1:5-diamino-4:8-dihydroxy-, and their condensation products (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 49. 1:5-, 1:6-, 1:7-, and 1:8- chloronitro- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 49. trichloro-, and dichlorobromo- (BADISCHE ANILIN- & SODA-FABRIK), A., i, 49. 4-amino-1-thiocyano-, and 1:4-*dithiocyano-* (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 333. 2-iodo- (ULLMANN), A., i, 751.
- Anthraquinones**, benzoylamine, preparation of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 751.
- Anthraquinone series** (ULLMANN), A., i, 270.
- Anthraquinoneacridone** (ULLMANN), A., i, 697.
- Anthraquinone 3-carbonamide 3-carboxylic acid** (WILLGERODT and MARFZZOLI), A., i, 678.

- Anthraquinone-2-carboxylic acid**, 3-amino-, and its salts and acetyl derivative, and 3-chloroacetylaminodibromide (WILGERODT and MAFFEZZOLI), A., i, 678.
- Anthraquinone-2:3-dicarboxylimide**, potassium derivative of (WILGERODT and MAFFEZZOLI), A., i, 679.
- Anthraquinonefluorescein**, and its salts and diacetyl derivative, and dibromo-, and tetrabromo- (WILGERODT and MAFFEZZOLI), A., i, 679.
- Anthraquinone-2-sulphonamide** (ULLMANN), A., i, 751.
- Anthraquinone-6-sulphonic acid**, 1:4-dichloro-, sodium salt (WALSH and WEIZMANN), T., 688.
- Anthraquinone-8-sulphonic acid**, bromo-, sodium salt and 1:4-dichloro- (BADISCHE ANILIN- & SODA-FABRIK), A., i, 270.
- Anthraquinonesulphonic acids**, halogen, preparation of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 396.
- 4:8-Anthraquinonylamino-1-N-methyl-anthrapyrimidone** (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 445.
- 8-Anthraquinonylcarbimide** (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 750.
- 1-Anthraquinonylglycine** (SEER and WEIZENBÖCK), A., i, 571.
- Anthraquinonyl-1:2-, 2:1-, and 2:3-quinolines**, nitro- (BADISCHE ANILIN- & SODA-FABRIK), A., i, 130.
- 1:2-Anthraquinonylsulphonamino-anthraquinone** (ULLMANN), A., i, 751.
- 1-Anthrathiazine** (LAUBE and LIRKIND), A., i, 494.
- 1-Anthrathiazole** and 4- and 5-amino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 338.
- 1-Anthrathiazole-4-mercaptan** (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 338.
- 1-Anthrathiazole-8-sulphonic acid**, 4-amino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 338.
- Anthroxanaldehyde**, oxime of (HELLER and TISCHNER), A., i, 65.
- Anthroxanic acid** (2-anthranilcarboxylic acid), relation between anthranil and (BAMBERGER and LINDBERG), A., i, 189.
- 5-bromo-** (HELLER and FRANTZ), A., i, 849.
- Anti-coagulating substance**, secreted by the liver (DOYON), A., ii, 427.
- Antidiastase**, presence of, in malt infusions (VANDEVELDE), A., ii, 645.
- Anti-leucoprotease** (BRADLEY), A., i, 795.
- Antimony**, spectrum of (ROYDS), A., ii, 87.
- Antimony**, influence of, on the system: iron and carbon (GOERKENS and ELLINGEN), A., ii, 298.
- Antimony compounds**, physiological action of (THOMSON and CUSHNY), A., ii, 330.
- Antimony alloys** with bismuth and copper (PARRAVANO and VIVIANI), A., ii, 779, 852.
- with copper and bismuth (PARRAVANO and VIVIANI), A., ii, 956, 1068.
- with tin, analysis of (McCAY), A., ii, 1008.
- Antimony ammonium tetrabromide** and ferric ammonium chloride (EHRHAIM and WEINBERG), A., ii, 41.
- halides, compounds of, with methylamine, ethylamine, and diethylamine (EHRHAIM and WEINBERG), A., ii, 41.
- hydride, estimation of (RECKLIZEN and GÜTICH), A., ii, 352.
- fluorides (EHRHAIM and HEY-MANN), A., ii, 37.
- trisulphide, varieties of (ZANI), A., ii, 219.
- Antimony**, estimation of (SANGER and RIEGEL), A., ii, 181.
- volumetric estimation of (SCHMIDT), A., ii, 551.
- arsenic and tin, estimation of, by means of potassium ferricyanide (PALMER), A., ii, 547.
- and tin, separation of, by distillation (PLATO), A., ii, 903.
- Antimony organic compounds**, aromatic (MAY), T., 1956: P., 142, 218; (MORGAN, MICKLETHWAIT, and WHITEY), T., 34; P., 151.
- Antimony poisoning** in compositors (SCHRIFF and ZABEL), A., ii, 986.
- Antiprotease** of yeast juice (BOCHNER and HAHN), A., i, 648.
- Antipyrine**, influence of, on the proteins of blood-serum (CERVELLO), A., ii, 515.
- detection of in pyrimidine (PRIMOT), A., ii, 83.
- Antithrombin** (HOWELL), A., i, 793.
- Antitrypsin** (COBLINER), A., ii, 623.
- formation of, in the organism (BRAUNSTEIN and KEMINOFF), A., ii, 786.
- and trypsin (MEYER), A., i, 211.
- of the blood and of urine, relation between (HIRATA), A., ii, 971.
- Antlerite**, identity of stelnzerite with (SCHALLER), A., ii, 1076.
- Aorta**, normal and atheromatous, amount of cholesterol and its esters in the (WINDAUS), A., ii, 733.
- Apatite** from Carrock Fell, Cumberland (FINLAYSON), A., ii, 305.

- Apnoea**, fatal, after excessive respiration (HENDERSON), A., ii, 137.
- Apocynum**, action of an active principle from (DALE and LAIDLAW), A., ii, 529.
- Aporrhagma** (ACKERMANN and KUTSCHER; ACKERMANN), A., ii, 1089; (ENGELAND and KUTSCHER), A., ii, 1090.
- Apparatus**, new (GRZESCHLE), A., ii, 893. for laboratories and lecture experiments (SCHOFIELD), A., ii, 1053; (THIELE), A., ii, 1054. for analytical practice (BEGER), A., ii, 747. for decantation (NETTO), A., ii, 540. gas-filling (LENHARD), A., ii, 493. for the distillation of fatty acids (BROWN and THOMAS), P., 149. for the estimation of sulphur and arsenic (KLEINE), A., ii, 719.
- Araconic acid** (BÖDDENER and TOLLENS), A., i, 490.
- Arbutin**, true, preparation of (HARRISSEY), A., i, 692. and methylarbutin, properties, distinction and detection in plants of (BOUQUELOT and FICHTENHOLZ), A., i, 273.
- Arc**. See under Electrochemistry.
- Arginine**, occurrence of, in the bull's testis (TOYANI and KATSUYAMA), A., ii, 825.
- dl-Arginine** (α -amino- δ -guanino- γ -valeric acid), synthesis of, and its benzoyl derivative (SØRENSEN), A., i, 227.
- Argon**, preparation of (FISCHER and HÄHNEL), A., ii, 608; (CLAUDE), A., ii, 1061. preparation and physical constants of (CROMMELIN), A., ii, 709. refraction and dispersion of (CUTHBERTSON and CUTHBERTSON), A., ii, 561. dielectric cohesion of (BOUTY), A., ii, 680. the ionic mobility in (FRANCK), A., ii, 478. experiments on the combining capacity of (FISCHER and SCHÖTER), A., ii, 608. solubility of, in water (v. ANTHOFF), A., ii, 409.
- Argon group**, gases of the, viscosities of (RANKINE), A., ii, 499, 829.
- Aromatic compounds**, new synthesis of, from aliphatic compounds (KOMENOS), A., i, 362. solid, threefold emission spectra of (GOLSTEIN), A., ii, 671.
- Arsanilic acid**. See Phenylarsinic acid, *p* amino.
- Arsenates**. See under Arsenic.
- Arsenic** in the Max spring at Duckheim a.d. Haardt (HINTZ), A., ii, 510. occurrence of, in soils, plants, fruits, and animals (HEADDEN), A., ii, 590. pure colloidal (LECOQ), A., ii, 406. toxicity of (LECOQ), A., ii, 431. phosphorescent oxidation of (BLAU), A., ii, 32. reduction of quinquivalent, by hydrogen bromide (KOHMER), A., ii, 774.
- Arsenious chloride**, reduction of, by hydrogen (BESSON and FORNIER), A., ii, 406.
- Arsenic trihydride**, synthesis of, from its elements (VOURNASOS), A., ii, 951. influence of, on the organism (DRUITZKI), A., ii, 983.
- Arsenious acid**, adsorption of, by ferric hydroxide (BILTZ), A., ii, 106; (REYCHLER), A., ii, 286. application of, in the estimation of dextrose (LITTENSCHIED and BORNEMANN), A., ii, 80.
- Arsenic acid**, action of, on gallic acid (LILIN), A., i, 908. reaction distinguishing the organic derivatives of, from those of arsenious acid (COVELLI), A., ii, 1012. detection of, in the presence of arsenious acid (LUTZ and SVINE), A., ii, 156. detection of, in presence of photophoric acid (MADEIRA), A., ii, 896. precipitation of, by ammonium molybdate (MADEIRA), A., ii, 896. detection and estimation of, in the presence of arsenious acid (BUTSCH and SMITH), A., ii, 1109.
- Arsenates**, action of, on the growth of algae (CONKRE), A., ii, 437.
- Arsenic organic compounds**, behaviour of, in the human body (FISCHER and HOPPE), A., ii, 432.
- Arsenoacetylauranilic acid** (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 84.
- Arseno-albumin**, preparation of (KLOPPER), A., i, 292.
- Arsenocetyl-oxy- and thioacetic acids**, preparation of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 452.
- Arsenobenzene**, *p*-di-iodo (MANEN and PATTA), A., i, 531.
- Arsenocresol**, *di*-amino- (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 804.

Arsenic organic compounds:—

Arsenozandelic acid and its sodium salt (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 452.

p-Arsenophenyl (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 148.

β-Amino-, and **tetra-amino-** (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 804.

Arsenophenylthiolacetic acid and its sodium salt (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 452.

Arsenosomolybdic acid, salts of (EPHRAIM and FRIDEL), A., ii, 301.

p-Arseno-o-tolylglycine (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 81.

Arsenoxidephenylthiolacetic acid (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 452.

Arsenic, detection and separation of (CARLSON), A., ii, 993.

apparatus for estimating (KAAENOWSKI), A., ii, 451; (KLEINE), A., ii, 749; (SWETT), A., ii, 895.

apparatus for estimation of, in iron and steel (PREUSS), A., ii, 1109.

estimation of (HARRIS), A., ii, 451; (JANNASCH and SEIDEL), A., ii, 546.

estimation of, in copper (AZZARELLO), A., ii, 241.

antimony and tin, estimation of, by means of potassium ferricyanide (PALMER), A., ii, 546.

Arsenious acid. See under Arsenic.

Arseno compounds. See under Arsenic.

Artemisia cana, occurrence of *l*-camphor in (WHITTELEY), A., i, 184.

Arterenal trimethyl ether, and its hydrochloride and platinumchloride (MAN-
SICH and NEUMANN), A., i, 413.

Arylalkyl-p-aminophenols, preparation of (CHEMISCHE FABRIK AUF AKTIEN VORM. F. SCHERING), A., i, 28.

Arylamines, additive compounds of *o*-nitrobenzene and (SUDBOROUGH and BEARD), T., 773; P., 71.

secondary, preparation of substituted indoles from (RICHARDS), T., 977; P., 92.

Arylhydrazonemesoxalyl-bis-hydrazone acetosacetic acids, ethyl esters, bisazo compounds of (BÜLOW and BOZENHARDT), A., i, 205.

Asaronic acid, preparation of (LUFF, PERKIN, and ROBINSON), T., 1133; P., 133.

Ascites, chylous and pseudo-chylous (WALLIS and SCHÜLBERG), A., ii, 635.

Asparagine, synthetic production of, in plants (PRIANISCHNIKOFF and SCHULOFF), A., ii, 885.

α-Asparagine, natural occurrence of (FRINGSHEIM), A., i, 303.

Asparagus, constituents of (WICHERS and TOLLENS), A., ii, 885, 886.

Aspartic acid, preparation of calcium and copper salts (ABDERHALDEN and KAUTSCH), A., i, 231.

racemic, behaviour of, on putrefaction (NEUBERG), A., i, 266.

polypeptides from (FISCHER and FIEDLER), A., i, 656.

separation and estimation of, and glutamic acid (OSBORNE and LITTLE), A., ii, 1007.

Asphyxia in the spinal animal (KAYA and STARING), A., ii, 50.

Association and viscosity (THOLE), T., 2596; P., 328.

Asymmetric synthesis, attempts at, by means of circularly-polarised light (PADOA), A., ii, 6.

Atmospheric air, refraction and dispersion of (CUTHERSON and CUTHERBERTSON), A., ii, 85.

radium, thorium, and actinium in (KEEZ), A., ii, 476.

disintegration products of radium and thorium in (PACINI), A., ii, 374.

ionisation of, the effect of dust and smoke on the (EVE), A., ii, 479.

by the carbon monoxide flame and by radium emanation (DE BROGLIE), A., ii, 570.

examination of, at various altitudes, for oxides of nitrogen and ozone (HAYHURST and PRING), T., 868; P., 92.

compressed, physiological effects of (HILL, MACKENZIE, ROWLANDS, TWOOT, and WALKER), A., ii, 1079.

liquid, phenomena observed on mixing, with water (V. WEIMANN), A., ii, 404.

method of demonstrating the properties of (REBENSTORFF), A., ii, 604.

estimation of very small amounts of ammonia in large quantities of (LIECHT and RUTHER), A., ii, 75.

estimation of carbon monoxide in (GOUTAL), A., ii, 157.

Atom, shape of the (KLEEMAN), A., ii, 704.

number of electrons in an (CROWTHER), A., ii, 918.

Atoms, the mechanical vibration of (SUTHERLAND), A., ii, 946.

and molecules, the nature of the force of attraction between (KLEEMAN), A., ii, 492.

- Atomic transpositions**, intramolecular (MONTAGNE and KOOPAL), A., i, 323; (MONTAGNE), A., i, 324.
- Atomic vibration**, fundamental constant of (SUTHERLAND), A., ii, 116.
- Atomic volumes**. See Volumes.
- Atomic weight**, a function of the volution of space-symmetry ratios (HOWARD), A., ii, 490, 600.
- determinations, vacuum correction of weighings applied to (GUYE and ZACHARIADES), A., ii, 116.
- of mercury (EASLEY), A., ii, 957.
- of nitrogen (GUYE and DROUGINIE), A., ii, 1056.
- of phosphorus (BAXTER and JONES), A., ii, 258.
- of platinum (ARCHIBALD), A., ii, 43.
- of silver, lithium, and chlorine (RICHARDS and WILLARD), A., ii, 292.
- of strontium (THORPE and FRANCIS), A., ii, 209.
- of tantalum (BALKE), A., ii, 962.
- of vanadium (PRANDTL and BLEYER), A., ii, 134.
- Atomic weights** of groups of the periodic system, relation between (SCHERINGA), A., ii, 491.
- calculation of (HINRICHS), A., ii, 26, 285.
- as mathematical functions (LORING), A., ii, 26.
- true, according to Stas's determinations (DUBREUIL), A., ii, 31, 290.
- report of the International Committee on, T., 1861; P., 190.
- table of, T., 1865; P., 193.
- Atomic weight values**, repeating figures in (LORING), A., ii, 1053.
- Atoxyl** (*sodium p-aminophenylarsinate*) (BLUMENTHAL), A., ii, 982.
- toxicity of (METO), A., ii, 640.
- reactions of (FIORI), A., ii, 1012.
- Atractylis gummifera*, principles of (ANGELICO), A., i, 403.
- Atropine**, action of, in anaphylaxis of guinea-pigs (AURE), A., ii, 985.
- physiological action of (CRUICK), A., ii, 1095.
- Atropine halogen acetamides** (EINHORN and GÜTTLER), A., i, 131.
- Aucubin**, presence of, in varieties of *Aucuba japonica* (LEBAS), A., ii, 63.
- Augite** from the Rhon basalts (GALKIN), A., ii, 721.
- Aurin perchlorate** (HOFMANN, KIRMREUTHER, and THAL), A., i, 168.
- Aurons** salts. See under Gold.
- Auto-adsorption** (LEWIS), A., ii, 934.
- Autolysis** (LINDEMANN), A., ii, 1054.
- study of, by physicochemical methods (BENSON and WELLS), A., ii, 978.
- action of mercury salts on (THURTELL), A., ii, 142.
- Availability** of hydrogen chloride in alcoholic solution, influence of water on the (LAPWORTH and PARTINGTON), T., 19.
- Avogadro's law**, calculation of the deviations from (GUYE), A., ii, 691.
- and liquid crystals (LEHMANN), A., ii, 193.
- Axinite** from California (SCHALLER), A., ii, 874.
- Azelaic semi-aldehyde** methyl ester and its bisulphite compound (HALLER and BROCHET), A., i, 217.
- Azides**, complex (MELDOLA and KENTZEN), P., 340.
- Azine**, $C_{12}H_{12}O_2N_2$ from polymerise of crotonaldehyde (DELEPINE), A., i, 219.
- Azinsuccinic acid**, methyl ester, unsymmetric (DARAFSKY), A., i, 485; symmetric (DARAFSKY), A., i, 486.
- o*-Azobenzamide (HELLER and WEINER), A., i, 596.
- Azobenzene**, absorption spectrum and colour of (CRYNDEL, STEWART, and WRIGHT), A., ii, 470.
- spontaneous crystallisation and melting- and freezing-point curves of mixtures of, and benzylamine (ISAAC), A., ii, 1034.
- compound of, with trinitrobenzene (HOFMANN and KIRMREUTHER), A., i, 548.
- perchlorate (HOFMANN, METZLER, and HOBOLD), A., i, 370.
- o*-chloro-*p*-hydroxy- (WOHLERSEN), A., i, 27.
- Azobenzenes**, stereomeric (GORTNER and GORTNER), A., i, 790.
- Azo-compounds**, colour and constitution of (HEWITT and THOLE), T., 511; P., 54.
- thermochemical investigations on (SVENSTOLAVSKY), A., ii, 588, 691.
- complex (MELDOLA and KENTZEN), P., 340.
- oxidation of (ANGELI), A., i, 615.
- o*-amino-, action of heat on (VANDER), A., i, 287.
- hydroxy-, salts and hydrate of (HANTZSCH and ROBERTSON), A., i, 203.
- nitrated, relation between absorption spectra and chemical constitution of (BALY, TUCK, and MARSDEN), T., 1494; P., 166.
- Azo-coupling**, influence of hydroxylation on (HELLER and GALLEY), A., i, 267.

- Azomide** (*hydrazoic acid, hydronitric acid*), condensation of, with fulminic acid (PALAZZO), A., i, 342.
 action of, on methylcarbamylamine (OLIVERI-MANDALÀ), A., i, 343.
 triazole and tetrazole from (DINROTH and FESTER), A., i, 645.
- Azomides** of the acetoacetic series (FOSTER and NEWMAN), T., 1360; P., 197.
- Azomidoheptylic acid**, ethyl ester (DINROTH and FESTER), A., i, 904.
- Azotimin**, commercial (SCHEITZ), A., i, 565.
- Azomethineazo-dyes** (GREEN and SEN), T., 2242; P., 243.
- Azomethylenefluorene** (WISNIEWSKI and RUSSE), A., i, 846.
- Azophenols**, chromoisomerism and homochromoisomerism of (HANTZSCH), A., i, 780.
- Azopyrazolones**, decomposition of, with concentrated nitric acid (BELOW, HAAS, and SCHMACHTENBERG), A., i, 902.
- Azotrychninesulphonic acid** (LEUCHS and BOLL), A., i, 766.
- Azotobacter**, influence of the mineral constituents of nutritive solutions on (KREMIENIEWSKA), A., ii, 987.
 fixation of nitrogen by (HOFFMANN and HAMMER), A., ii, 988.
- Azotoluene** (THIELKE), A., i, 890.
- Azotoluenedihydrazinesulphonic acids** and their salts (TRIGER and WESTERKAMP), A., i, 207.
- Azoxybenzamide** (HELLER and WEIDNER), A., i, 596.
- Azoxybenzene-*o*-carboxylic acid** (FREUNDLER), A., i, 138.
- 2:2'-Azoxybenzoic acid**, 3:6:3':6'-tetra-chloro- (BAMBERGER and ELGAR), A., i, 269.
- Azoxycinamic acid** (HELLER and TSCHNER), A., i, 597.
- Azoxy compounds**, preparation of (REITZENSTEIN), A., i, 702.
- 2'-Azoxydiphenylmethane-4,4'-dicarboxylic acid**, ethyl ester (DEVAL), A., i, 580.
- Azoxyphenetole**, absorption of carbon dioxide by, relation between solubility and the physical state of the solvent in the (HOMFRAY), T., 1669; P., 197.
- B.**
- Bacilli**, dysentery, action of, on nitrates and nitrites (LOGIE), A., ii, 988.
 Koch's, preparation of a culture medium from (BAUDRAX), A., ii, 331.
- Bacillus anthracis**, proteolytic power of (BIELECKI), A., ii, 642.
phaenanthracis, fermentation of formic acid by (FRANZEN and GREVE), A., ii, 799.
tuberculosis, utilisation of amino-acids and polypeptides by (KORLKER and HAMMER), A., ii, 737.
- Bacteria**, assimilation of carbon by (LEBEDEFF), A., ii, 229.
 assimilation of nitrogen by (BORTOMLEY), A., ii, 988.
 accumulation of nitrogen in soils by free (KUCH), A., ii, 60.
 enzymes in (ABERHALDEN, FINCUS-SOHN, and WALTHER), A., ii, 989.
 and other micro-organisms, growth of, in atmospheres enriched with oxygen, (MOORE and WILLIAMS), A., ii, 737.
 rate of death of, in oxygen (PAULI, BERNSTEIN, and REUSS), A., ii, 642.
 production of nitrous oxide by (TACKER), A., ii, 231.
 putrefaction of fibrin by (McCREDEN), A., ii, 988.
 decomposition of nitrates by (SEWERIN), A., ii, 148.
 fermentation products of, determination of volatile acids in (SEIBER), A., ii, 642.
 soil, influence of depth of cultivation on (KING and DORYLAND), A., ii, 231.
 See also *Bacillus*, Fermentation, and Yeast.
- Bacterium putidum**, hemolysis of (BURCKHARDT), A., ii, 799.
- Balsam, cubebae** (TSCHIRCH and WERMULLER), A., i, 639.
- Honduras** (TSCHIRCH and WERMULLER), A., i, 638.
- Barbierite** (SCHALLER), A., ii, 1078.
- Barium**, band spectrum of (LECOQ DE ROUSSEAU), A., ii, 3.
 infra-red line spectrum of (RANDALL), A., i, 1014.
 and magnesium, antagonistic action of (JOSEPH and MENTZER), A., ii, 228.
- Barium, ammonium arsenosomolybdate** (EPHRAIM and FEIDEL), A., ii, 301.
 chloride, action of, on the frog's heart (POLLISON), A., ii, 529.
 mercuric chloride (SCHERINEMAKERS), A., ii, 490.
 zinc chloride, and iodide (EPHRAIM and MODEL), A., ii, 851.
 hydroxide and nitrate, solubility of, in the presence of each other (PARSONS and CORSON), A., ii, 1065.

- Barium nitrate and hydroxide, solubility of, in the presence of each other** (PARSONS and CORSON), A., ii, 1065.
- nitride, preparation of** (WOLK), A., ii, 849.
- mercuric nitrite** (RAY), T., 326; P., 7.
- oxytrithiophosphate, dioxydithiophosphate and dioxyselenophosphate** (EPHRAIM and MAJLER), A., ii, 206.
- sulphate** (OECHSNER DE CONINCK), A., ii, 612.
- solubility of, at high temperatures** (MELCHER), A., ii, 293.
- colloidal** (KATO), A., ii, 850.
- adsorption of uranium-X by** (BERRY), T., 196; P., 6.
- and hydrogen sulphate** (ROHLAND), A., ii, 411.
- ethyl sulphate, decomposition of, in acid and alkaline solutions at different temperatures** (KREMANNS), A., ii, 596.
- Barium, estimation of** (HUYBRECHTS), A., ii, 898.
- volumetric estimation of** (SELVATICI), A., ii, 454.
- Barley, sterilisation of** (SCHROEDER), A., ii, 1103.
- influence of copper and manganese sulphates on the growth of** (BRENNER), A., ii, 889.
- "Barytocelestine" from Binneenthal, Switzerland** (ROSICKY), A., ii, 309.
- Basalt, radium content of** (STRITT), A., ii, 1025.
- Base, $C_6H_{12}N$, from isopentane and ammonia** (LOSANITSON), A., i, 543.
- $C_6H_{12}ON_2$, from ether and ammonia** (LOSANITSON), A., i, 543.
- $C_{10}H_{27}O_3N_2$, and its hydrochloride, from α -limonene bisnitrosochloride and hydroxylamine** (CISMANO), A., i, 686.
- $C_{15}H_{21}ON$, from acetylcamphor- m -hydroxyl, and its picrate** (BORSCHKE, SCHMIDT, TIEDTKE, and ROTTSTEFER), A., i, 882.
- $C_{22}H_{45}O_2N$, from reduction of corycavine, and its anilichloride** (GABEL), A., i, 502.
- Bases and acids, relations between the strength of, and the quantitative distribution of affinity in the molecule** (FLIESCHMANN), T., 84.
- externally compensated, resolution of** (POPE and KEAD), T., 987; P., 118.
- action of, on ethnal hydrate** (ENKLAAR), A., i, 299.
- Bases, action of, on the α,α -dibromo-derivatives of dicarboxylic acids** (LE SEUEUR and HAAS), T., 173; P., 4.
- aromatic, additive compounds of, and mercury salts** (STARONKA), A., i, 876.
- organic, and acids, solubility of, in solutions of their salts** (STEWART), P., 60.
- iron double salts of** (SCHOLIZ), A., i, 97.
- compounds of acid dyes with** (RADLBERGER), A., i, 760.
- action of cyanogen bromide and of phosphorus halides on** (V. BRATN), A., i, 189.
- Basic slag.** See Slag, basic.
- Batracholin, a nucleo-protein in frog's eggs** (McCLENDON), A., ii, 54.
- Beckmann rearrangement** (MONTAGNA), A., i, 623.
- Beef, phosphorus in** (FRANCIS and TROWBRIDGE), A., ii, 781, 792.
- nutritive value of fish in comparison with** (SLOWITZOFF), A., ii, 828.
- extracts of, presence of glyceronic derivatives in** (GRIMBERG and TRIPAUD), A., ii, 979.
- Beer, value of, in the organism** (VOLTZ, FERNSTER, and BAUDREUIL), A., ii, 975.
- detection of saponin in, by haemolysis** (RUSCONI), A., ii, 559.
- Beer yeast.** See Yeast.
- Bees, respiration of** (PARSON), A., ii, 513.
- Beet (sugar), composition of** (ASCHBACH, BARTIS, and URBAN), A., ii, 152.
- estimation of sugar in the** (ANDRIK and STANER), A., ii, 463.
- Behenic acid, dibromo-, calcium, strontium, and magnesium salts** (FABER-FABRIKEN VORM. F. BAYER & Co.), A., i, 215.
- Beilstein reaction for halogens** (MURROTH), A., ii, 67.
- Benincopalonic acid** (KAHAN), A., i, 689.
- Benincopallic acid** (KAHAN), A., i, 689.
- α - and β -Benincopalonic acids** (KAHAN), A., i, 689.
- α - and β -Benincopallic acids** (KAHAN), A., i, 689.
- α -, β -, and γ -Benincopaloresins** (KAHAN), A., i, 689.
- Benitoite, paragenesis and occurrence of** (LOUDERBACK and BLASDALE), A., ii, 310.
- Benzaldazine, m -hydroxy-** (NOELING), A., i, 177; (FRANZEN and EICHLER), A., i, 709.
- p -hydroxy-** (FRANZEN and EICHLER), A., i, 709.

- Benzaldehyde**, action of light on, in presence of iodine (MASCARELLI), A., i, 389, 746; (MASCARELLI and BOSINELLI), A., i, 561.
 action of ethyldiazoacetate on (DRECKMANN), A., i, 385.
 condensation of, with guaiacol (MANTROT), A., i, 314.
 condensation of, with 2-naphthol-3-carboxylic acid (FRIEDL), A., i, 741.
 condensation of, with resorcinol (POPE and HOWARD), T., 78.
 action of, on the monosodium derivative of phenylacetone nitrile (BODROUX and TABOURY), A., i, 622.
 dimeric (MASCARELLI), A., i, 389.
 di-*o*-substituted, preparation of triphenylmethane colouring matters from (ANILINFARBEN- & EXTRACT-FABRIKEN FORM. J. R. GEIGY), A., i, 175.
 sulphide. See 4-Aldehydophenyl sulphide.
- Benzaldehyde**, *m*-amino-, preparation of salts of, in the presence of anhydro-*o*-aminobenzaldehyde (FABRIK-FABRIKEN FORM. F. BAYER & Co.), A., i, 390.
 2-chloro-6-bromo-, 2-chloro-4:6-*di*-bromo-5-amino-, 2:4:6-*tri*bromo-5-amino-, and 2-chloro-4:6-*di*bromo-5-hydroxy- (ANILINFARBEN- & EXTRACT-FABRIKEN FORM. J. R. GEIGY), A., i, 175.
 α -cyano-, nitro- and chloro-nitro-phenylhydrazones, and nitrotolylhydrazones (PONZIO and GIOVETTI), A., i, 195.
p-hydroxy-, hydrobromide (GOMBERG and CONE), A., i, 872.
 2:3-dihydroxy-, and its derivatives (PATLY and LOCKEMANN), A., i, 561.
o-nitro-, chemical action of light on (BAMBERGER and ELGAR), A., i, 268.
 2:4:6-*tri*nitro-, diacetate (SPATH), A., i, 488.
- Benzaldehydhenzylhydrazone**, formation of (BUSCH and FLEISCHMANN), A., i, 282.
- Benzaldehyde-*o*-chloro-*p*-nitrophenylhydrazone**, ω -amino-, and its oxalate and hydrochloride (PONZIO), A., i, 444.
- Benzaldehydiisobutylacetal**, *o*-nitro-, (BAMBERGER and ELGAR), A., i, 268.
- Benzaldehydiethylacetal**, *o*-nitro-, (BAMBERGER and ELGAR), A., i, 268.
- Benzaldehydiphenylethylhydrazone** and its hydrochloride (BUSCH and FLEISCHMANN), A., i, 282.
- Benzaldehydipropylacetal**, *o*-nitro-, (BAMBERGER and ELGAR), A., i, 268.
- Benzaldehydiisopropylacetal**, *o*-nitro-, (BAMBERGER and ELGAR), A., i, 268.
- Benzaldehyde-*o*-nitrophenylhydrazone**, ω -amino-, and its hydrochloride and ω -nitro- (PONZIO), A., i, 443.
- Benzaldehyde-*p*-nitrophenylhydrazones**, ω -amino-, and its oxalate and hydrochloride and ω -nitro-, action of ammonia on (PONZIO), A., i, 442.
- Benzaldehyde-*o*-nitro-*p*-tolylhydrazone**, ω -amino-, and its hydrochloride (PONZIO), A., i, 444.
- Benzaldehyde-*p*-nitro-*o*-tolylhydrazone**, ω -amino-, and its oxalate and hydrochloride (PONZIO), A., i, 443.
- Benzaldehydesulphoxylic acid**, sodium, barium, and zinc salts (BAZLEN), A., i, 40.
- Benzaldehyde-*m*-tolylhydrazone** (PADOA and GRAZIANI), A., i, 135.
- Benzaldehyde-*p*-tolylmercaptal** (FROMM and RAIZISS), A., i, 555.
- Benzaldehyde 1:2:4-**, and 1:3:4-, and 1:4:5-xylylhydrazones (PADOA and GRAZIANI), A., i, 509, 778.
- Benzamarone**, α -, β -, and *p*-nitro- (STOBBE and WILSON), A., i, 624.
- Benzamide**, ammonium benzoate and water, the system (LEID), A., ii, 701.
- Benzamide**, α -, β -, and *p*-fluoro- (MEYER and HUB), A., i, 735.
- Benzamide-*o*-azobenzonic acid** (HEILIG and WEIDNER), A., i, 596.
- Benzamidine**, *o*-nitro-, and its platinum-chloride (MATSUI), A., i, 690.
- Benzanilide**, 3:5-*di*-iodo-2-amino- (*meso*-Benzdianthrone, and *tetrabromo-* (SCHOLZ, MANSFIELD, and POTTSCHWALSCHIEG), A., i, 494.
- Benzene**, vapour pressure of (BAKER), A., ii, 185; (SMITH and MENZIES), A., ii, 1047.
 and bromo- and chloro-benzene, expansion of (V. BIRN), A., ii, 393.
 and nitrobenzene, heats of liquefaction of (MEYER), A., ii, 182.
 separation of cyclohexane from mixtures containing (PATTERSON and FLECK), T., 1773; P., 207.
- Benzene derivatives**, absorption spectra and constitution of (WALLACHUKO), A., ii, 1015.
 morphological studies of (ARMSTRONG), T., 1578; P., 139; (COLGATE and ROBB), T., 1585; P., 139.
 isomeric, freezing-mixtures of (BRUNI), A., i, 467.

- Benzene** and its homologues, presence of ethylene linkings in (CHARITSCH-KOFF), A., i, 104.
 synthesis of a polymeride of (LOSA-NITSCH), A., i, 2.
 absorption of, from the air, by men and animals (LEHMANN, GUNDERMANN, STÜHR, and KLEINER), A., ii, 875.
 molecule, space representation of (EARL), A., i, 104.
 nucleus, mechanism of substitution in (WIELAND and WECKER), A., i, 242.
 orientation in the (OBERMILLER), A., i, 826.
Benzene, estimation of, in alcohol (WOLFF), A., ii, 1116.
Benzene, 1:3-dichloro-4-iodo-, and 1:3-dichloro-4-iodoso- (WILGERODT and BÜLLERT), A., i, 827.
 iodoso-, behaviour of, in the animal organism (LUZZATTO and SATTA), A., ii, 433.
 as-, and *s-trichloroiodoso*-, and *as-trichloroiodoxy*-, and their salts (WILGERODT and WILCKE), A., i, 828.
 iodoxy-, behaviour of, in the animal organism (LUZZATTO and SATTA), A., ii, 984.
 nitro-, reduction of, to aniline (OTIN), A., i, 727.
 1-chloro-2:4-dinitro-, action of, on pyridine bases, and platinumchlorides of additive compounds (REITZENSTEIN and STANN), A., i, 283.
 1:3-dichloro-4:6-dinitro-, action of pyridine on (ZINCKE and WEISPFENNING), A., i, 585.
s-trinitro-, additive compounds of, with arylamines (SUDBOROUGH and BEARD), T., 773; P., 71.
 additive compounds with hydrazine, phenylhydrazine and azobenzene (HOFMANN and KIRCHHEIMER), A., i, 548.
 nitroso-, condensation of, with chloranthranilic esters (FREUNDLER), A., i, 445.
Benzeneazooacetohydrazide, and *p*-nitro- (DIMROTH and DE MONTMOLLIN), A., i, 899.
N-**Benzeneazooacetophenylhydrazine** (DIMROTH and MERZBACHER), A., i, 897.
Benzeneazo- α -, - m -, and - p anisoylacetie acid methyl esters (WAHL and SILBERZWEIG), A., i, 263.
Benzeneazobenzenediazonium chloride, dichromate and platinumchloride (HEWITT and THORP), T., 514; P., 54.
5-Benzeneazo-2-benzylglyoxalidone, *p*-nitro- (FINGER and ZEN), A., i, 591.
5-Benzeneazo-1- m -bromophenyl-6-pyridazone-3-carboxylic acid, *m*-bromo-, ethyl ester (HENRICH, REICHENBURG, NACHTIGALL, THOMAS, and BAUM), A., i, 902.
5-Benzeneazo-1- p -chlorophenyl-6-pyridazone-3-carboxylic acid, *p*-chloro-, ethyl ester (HENRICH, REICHENBURG, NACHTIGALL, THOMAS, and BAUM), A., i, 902.
Benzeneazodiacetylhydrazine, *p*-nitro- (DIMROTH and DE MONTMOLLIN), A., i, 899.
Benzeneazodibenzoylhydrazine (DIMROTH and DE MONTMOLLIN), A., i, 899.
Benzeneazodiphenylphenol, *p*-nitro- (FICHTER and WALTER), A., i, 29.
4-Benzeneazo-1:3-diphenyl-5-pyrazolone-2-carboxylic acid (MICHAELIS and LEO), A., i, 516.
4-Benzeneazo-3-furyl-5-pyrazolone (TORREY and ZANETTI), A., i, 893.
7-Benzeneazoglutaconic acid, ethyl ester, phenylhydrazone (HENRICH, REICHENBURG, NACHTIGALL, THOMAS, and BAUM), A., i, 901.
m-bromo-, ethyl ester, *m*-bromophenylhydrazone (HENRICH, REICHENBURG, NACHTIGALL, THOMAS, and BAUM), A., i, 902.
p-chloro-, ethyl ester, *p*-chlorophenylhydrazone (HENRICH, REICHENBURG, NACHTIGALL, THOMAS, and BAUM), A., i, 902.
Benzeneazohydrazinedicarboxylic acid, tribromo-, ethyl ester (DIMROTH and DE MONTMOLLIN), A., i, 899.
5-Benzeneazo-8-hydroxyquinoline, and *p*-acetyl-amino-, *p*-amino-, *p*-bromo-, and *p*-nitro-, and their derivatives (FOX), T., 1339; P., 177.
Benzeneazomethylenefluorene, *p*-bromo-, and its dibromide (WISLIEWSKI and RUSS), A., i, 840.
4-Benzeneazo- α -naphthol, 5-nitro-8-acetyl-amino- (FICHTER and KERN), A., i, 108.
Benzeneazo- α - and - β -naphthylhydrazine sulphonic acids, and their salts (TROGER and WESTERHAMP), A., i, 208.
Benzeneazo- ω -nitrophenylacetonitrile (PONZIO and GIOVETTI), A., i, 195.
4-Benzeneazo-1-nitroso-5-hydroxy-3-methylpyrazole (BELOW, HAAS, and SCHMACHTENBERG), A., i, 903.

- Benzene 1:3:5-trisulphonylter-*p*-amino-benzenazo- β -naphthol** (MORGAN and PICKARD), T., 56.
- Benzene 1:3:5-trisulphonylter-*m*- and *p*-nitroanilines** (MORGAN and PICKARD), T., 54.
- Benzene 1:3:5-trisulphonylter-*p*-phenylenediamine** (MORGAN and PICKARD), T., 55.
- Benzene 1:3:5-trisulphonylter-*p*-phenylenediazoidime** (MORGAN and PICKARD), T., 54.
- Benzenyl-4-amino-3-thiocresol platinichloride** (WHEELER and LIDDLE), A., i, 17.
- Benzhydrol, *di-p*-bromo-** (BILTZ, EDLERSSEN, and SEYDEL), A., i, 570; (BILTZ), A., i, 621.
- 2:4-*di*-hydroxy-, and its dipotassium compound** (POPE and HOWARD), T., 80.
- Benzhydroxamic acid, menthonyl ether of** (CUSMANO), A., i, 51.
- Benzidine formation** (DUVAL), A., i, 559, 583, 618.
- derivatives, acetylation of** (CAIN and MAY), T., 720; P., 71.
- the use of, for the detection of minute traces of blood** (McWEEKEY), A., ii, 84.
- quinonoid-chloroimide** (KROCK), A., i, 325.
- Benzidine reaction, medico-legal aspect of, in examination of blood-stains** (BOURAS), A., ii, 364.
- Benzil and dibenzil, cryoscopic behaviour of** (MASCARELLI and MESSATTY), A., ii, 390.
- Benzil, *di-p*-bromo-, and its oxime and phenylhydrazone** (BILTZ, EDLERSSEN, and SEYDEL), A., i, 570.
- 1:1'-*di*-chloro-, and its hydrazone** (KENNER and WITHAM), T., 1967.
- Benzilic acid, action of thionyl chloride on** (STOLLÉ), A., i, 737.
- Benzilic acid, *di-p*-bromo-** (BILTZ, EDLERSSEN, and SEYDEL), A., i, 570.
- β -Benzil- β -naphthylsazone** (PAIDIA and SANTU), A., i, 779.
- β -Benzil-*o*- and *p*-tolylsazone** (PAIDIA and SANTU), A., i, 779.
- Benziminazole-2-benzoic acid, phenylhydrazide, and salts, methyl and ethyl ester and their methiodides, and nitro-** (RUPE and THIESS), A., i, 72.
- Benziminomethyl ether methyl hydrogen sulphate, and platinichloride** (MATSUI), A., i, 695.
- o*-nitro-, and its derivatives** (MATSUI), A., i, 696.
- Benziminylbenzylglyoxalidone** (FINGER and ZIEH), A., i, 591.
- Benzo-*sec*-butylamide, 2:4-diacyl-amino-** (BOGERT, AMEND, and CHAMBERS), A., i, 896.
- Benzocycloheptadienone and its *delta*-imide** (THIELE and WEITZ), A., i, 554.
- Benzocycloheptanol** (THIELE and WEITZ), A., i, 855.
- Benzoic acid, change of, into salicylic acid in sunlight** (NEUBERG), A., ii, 814.
- esterification of, by mesaptau (REID), A., i, 481.**
- behaviour of, in fowls, in the presence of glycine** (YOSHIKAWA), A., ii, 880.
- detection of, in meat and fat** (FISCHER and GRUENERT), A., ii, 1121.
- estimation of, in foods** (VAN DER LAAN and TYDENS), A., ii, 759.
- Benzoic acid, ammonium salt, benamide and water, the system** (REID), A., ii, 701.
- bismuth salts of** (GODFREIN), A., i, 842.
- sodium salt, existence in solution of compounds of caffeine and** (PELLINI and AMADORI), A., i, 416.
- action of, on the production of gas by bacteria** (HERTER), A., ii, 147.
- late of, in the human organism** (DAKIN), A., ii, 223.
- behaviour of ureides and purine derivatives towards solutions of** (PELLINI and AMADORI), A., i, 525.
- Benzoic acid, *m*-chlorophenyl and *o*-bromophenylesters of** (WOHLERSEN), A., i, 27.
- menthyl ester of** (COHEN and DUDLEY), T., 1750.
- Benzoic acid, *p*-amino-, *n*-propyl ester** (FRITZSCHE & Co.), A., i, 32.
- p*-nitro-, dialkylaminoalkyl esters and their derivatives** (EINHORN and UHLFELDER; EINHORN, FIEDLER, LAMISCH, and UHLFELDER), A., i, 170.
- isobutyl esters** (FARBENFABRIKEN VORM F. BAYER & Co.), A., i, 381.
- o*-acetyl-amino-, piperidino-ethyl ester and its hydrochloride** (EINHORN and UHLFELDER), A., i, 171.
- 2:5-diacylamino-** (BOGERT, AMEND, and CHAMBERS), A., i, 894.
- alkoxy- and alkylamino-, derivatives of, rotation of the menthyl esters of the** (COHEN and DUDLEY), T., 1752; P., 209.
- 3:4-diamino-, esters and alkylamino-esters and their derivatives** (EINHORN and UHLFELDER), A., i, 172.

- Benzoic acid**, 2-chloro-3:5-*d*-nitro-, action of pyridine on (ZINCKE), A., i, 556.
- 5-chloro-2-nitroso-, ammonium salt of (HELLER and FRANTZ), A., i, 849.
- o*-, *m*-, and *p*-fluoro-, methyl esters of (MEYER and HUB), A., i, 735.
- o*-hydroxy-, condensation of formaldehyde with (ERSTEIN), A., i, 117.
- estimation of, as tribromophenol bromide (AUTENRIETH and BEUTTEL), A., ii, 552.
- 2:4-*d*-hydroxy, methyl ester (v. BAEYER, AICKELIN, DIEHL, HALLENBERG, and HESS), A., i, 249.
- 4-iodo-2-amino-, 4-iodo-2-nitro-, and 4:5-*di*-iodo-2-amino-, and ethyl ester of the latter (WHEELER and JOHNS), A., i, 843.
- 2-iodo-3-acetylamino-, 3-iodo-4- and 5-amino-4-acetylamino-, and 5-nitro-, 5-iodo-2-acetylamino-, 3:4- and 3:5-*di*iodo-, 3:5-*d*-iodo-4-amino-, ethyl ester of, and 3:4:5-*tri*iodo- (WHEELER and LIDDLE), A., i, 18.
- 6-iodo-3-acetylamino- (WHEELER and HOFFMAN), A., i, 662.
- 2:5-*d*-iodo-, and its sodium salt and ethyl ester, 3:5-*d*-iodo-2-amino-, and its salts, ethyl ester and amide, and 2:3:5-*tri*iodo-, and its sodium salt (WHEELER and JOHNS), A., i, 381.
- m*-nitro-, *o*-, *m*-, and *p*-chlorophenyl and *p*-iodophenyl esters of (WOHLLEGEN), A., i, 27.
- 3:5-*d*-nitro-4-hydroxy-, coloured compounds of, with hydrocarbons (MORGENSTERN), A., i, 482.
- o*-nitroso-, propyl, isopropyl and isobutyl esters, and 3:6-*d*-chloro-2-nitroso- (RAMBERGER and ELGAR), A., i, 268.
- d*-thio (phenylcarbothionic acid), bismuth and iron salts and methyl and ethyl esters (BLOCH and HÖHN), A., i, 256.
- Benzoic acid**, separation of cinnamic acid and (DE JONG), A., ii, 81.
- detection of, in wine (VON DER HEIDE and JAKOB), A., ii, 359.
- Benzoic acids**, substituted, solubility in water and melting-point curves of (FLASCHNER and RANKIN), A., i, 255.
- d*-chloro- (ULLMANN and WAGNER), A., i, 254.
- benzoic acid cycloid**, *p*-benzoylamino- (HELLER and TISCHNER), A., i, 770.
- Benzoic anhydride**, *p*-diacetylamino- (HELLER and TISCHNER), A., i, 770.
- m*-bromo- (DANAILA), A., i, 381.
- p*-chloro- (LOCKEMANN, LORENSTEIN, EXNE, and HEROLD), A., i, 637.
- o*-Benzoisulphinide ("saccharin"), estimation of, in foods (TESTONI), A., ii, 167.
- detection and estimation of, in foods (TORTELLI and PIAZZA), A., ii, 908.
- estimation of, in urine and feces (BLOOR; WAREMAN), A., ii, 1011.
- Benzoins**, substituted imides from (RICHARDS), T., 977; U., 92.
- 7-Benzoin**, optically active glycols from (MCKENZIE and WREN), T., 473; P., 51.
- Benzoins**, 2:2'-*d*-nitro-, existence of (EKECRANTZ and AHLQVIST), A., i, 859.
- 2 Benzo- α -naphthol**, and its benzoyl derivative, metallic salts and piperidine salt (EDMONSON and HILMUTH), T., 226.
- Benzophenone**, dimorphism of (SCHAUW), A., i, 331.
- action of, on hydrocarbons under the influence of sunlight (PATERNO and CHIEFFI), A., i, 41.
- electrolytic reduction of (MÖLLER and KOPPE), A., ii, 387.
- and diphenylmethane, cryoscopic behaviour of (MASCARELLI and MUSATTI), A., ii, 390.
- Benzophenone**, 2:4:6-*tri*bromo-, action of heat on (MONTAGNE), A., i, 42.
- p*-chloro-, α - and β -chloroimides of (STIEGLITZ and PETERSON), A., i, 323.
- 2:4-*di*hydroxy-, new synthesis of (FISCHER), A., i, 248.
- Benzophenone-3:4'-dicarboxylic acid** (LAVAUZ and LOMBARD), A., i, 718.
- Benzophenoneimine** derivatives, preparation of (MOORE), A., i, 281.
- Benzophenoneoxime**, 2-chloro- (MONTAGNE and KOOPAL), A., i, 323.
- Benzophenonephenylimine**. See Diphenylmethylenedianiline.
- Benzophosphide** (EVANS and TILT), A., i, 968.
- α -Benzopinacolin, chlorine derivatives of (SCHMIDLIN and v. ESCHER), A., i, 369.
- α - and β -Benzopinacolin, decomposition of (DELAURE), A., i, 120.
- isomerisation and constitution of (DELAURE), A., i, 323.
- Benzopinacolin**, α -s:4:4'-*d*-chloro- (MONTAGNE and KOOPAL), A., i, 323.

- α*-Benzopinacolins**, influence of substituents of the phenyl group on the transformation of, into *β*-pinacolins (MONTAGNE and KOOPAL), A., i, 323.
- Benzopinacone**, 4:4'-dibromo- (MONTAGNE), A., i, 324.
- Benzopinacones**, influence of substituents of the phenyl group on the transformation of, into benzopinacolins (MONTAGNE), A., i, 324.
- Benzo-*γ* pyrone**, salts of (GOMBERG and COKE), A., i, 372.
- o*-Benzoquinone**, mechanism of reactions of (MICHAEL), A., i, 743.
- action of hydrogen chloride on (MICHAEL and COKE), A., i, 743.
- action of, on diamines and esters of amino-acids (SIEGMUND), A., i, 749.
- o*-Benzoquinoneoxime**, 4-chloro-6-nitro-3-hydroxy-, and 6-nitro-4-nitroso-amino-3-hydroxy- (HELLER and SOURLIS), A., i, 749.
- p*-Benzoquinone-2:5-diaminobenzoic acid**, methyl ester of (SIEGMUND), A., i, 749.
- o*-Benzoquinoneoxime-4-azo-8-naphthol**, 6-nitro-3-hydroxy- (HELLER and SOURLIS), A., i, 750.
- Benzoyl disulphide**, 3:5-di-iodo-2-amino- (WHEELER and JOHN), A., i, 332.
- Benzoyl acetic acid**, behaviour of, in the animal body (FRIEDMANN), A., ii, 735.
- ethyl ester, *o*-carboxyphenylhydrazone of (MICHAELIS and LEO), A., i, 515.
- γ*-Benzoylalanine**, lactone of, and its use in synthesis of benzoylated dipeptides (MOHR and STROSCHEIN), A., i, 483.
- Benzoylalanyl-*α*-aminoisobutyric acid** and its amide and lactone (MOHR and STROSCHEIN), A., i, 483.
- Benzoylanthranil**, constitution of (MEMM and HESSE), A., i, 770.
- Benzoylanthranilic acid**, acetylaminomethylanthranic acid (acetyl-anthranic acid) lactone and amide of (MOHR and KÖHLER), A., i, 116.
- Benzoylanthraquinone-1-thiol** (SEER and WEITZENBÖCK), A., i, 571.
- Benzoylasparagine** (PAULY and WEIR), A., i, 256.
- Benzoylaspartic acid**, methyl hydrogen and dimethyl esters and derivatives (PAULY and WEIR), A., i, 256.
- Benzoylation**, anomalous products of (HELLER and TISCHNER), A., i, 770.
- o*-Benzoylbenzoic acid**, *p*-bromo- (KOLLER, HERITAGE, and BURNLEY), A., i, 563.
- Benzoyl-*p*-bromoanilino-*αβ*-furodiarole** (BOESEKEN and COUVERT), A., i, 644.
- Benzoyl-*p*-bromobenzylidenehydrazine**, *p*-bromo- (CURTIUS, MELSBACH, and RISSOM), A., i, 509.
- Benzoylcarbamie acid**, halogen-substituted propyl and isopropyl esters of (JOHNSON and GUEST), A., i, 886.
- Benzoylcarthamine** (KAMETAKA and PERKIN), T., 1421; P., 181.
- L*- and *D*-Benzoylcaryoximes**, tetra-bromo- (DEUSSEN and HAHN), A., i, 273.
- Benzoyl-*m*-chlorobenzylidenehydrazine**, *m*-chloro- (CURTIUS, MELSBACH, and RISSOM), A., i, 509.
- Benzoyl-*m*-chlorophenylalanine** (FLATOW), A., i, 321.
- O*- and *N*-Benzoyl-5-chlorosalicylamide** (TITCHELEY and HUGHES), T., 1380; P., 175.
- α*-Benzoyl-*γ*-cinnamoyl-*β*-phenylbutyric acid**, ethyl ester and its *o*-bromide (BORSCHKE), A., i, 633.
- Benzoyldihydromesobenzdianthrone**, *β*-*p*-bromo- (SCHOLL, MANSFELD, and POTTSCHWAUSCHKE), A., i, 495.
- Benzoyldihydrodavanthron**, *p*-bromo- (POTTSCHWAUSCHKE), A., i, 517.
- 2-Benzoyl-3:4-dimethoxybenzoic acid** (FALTS), A., i, 638.
- 2'-Benzoyldiphenylsulphide**, 2:4-dinitro- (MAYER), A., i, 262.
- γ*-Benzoyl-*αβ*-diphenylbutyric acid** and its ethyl ester (BOISSELET), A., i, 25.
- β*-Benzoyl-*α*-diphenylethylhydrazine** (BUSH and FLEISCHMANN), A., i, 282.
- 3-Benzoyl-1:1-diphenyl-2-styryl-4-phenylbutanone** and its bromo-derivative (STAUDINGER and BURCHWITZ), A., i, 47.
- N*-Benzoyldiphenylbiourazole** (BUSH, REINHARDT and LINPACH), A., i, 142.
- Benzoylenebenziminazole**, and its salts, and amino-, and nitro- (RUPPE and THIESS), A., i, 71.
- Benzoylenecarhamide**, synthesis of (FINGER and ZEH), A., i, 332.
- 3-amino-**. See Tetrahydroquinazoline-2:4-dione, 3-amino-.
- Benzoyl ethyl-4-aminonaphthalene-1:4-diazonium salts** (MORGAN and COUZENS), T., 1694.
- αβ*-Benzoyl ethyl-1:4-naphthalenediamine** and its diazo-derivatives (MORGAN and COUZENS), T., 1693; P. 163.
- Benzoyl leuxanthrone** (ZERNER), A., i, 694.
- Benzoylfurylalanine** (FLATOW), A., ii, 322.
- Benzoylhistidine**, *p*-nitro- (PAULY), A., i, 336.

- Benzoylhydrazine, 2:4-diacetylamino- (BOGERT, AMEND, and CHAMBERS), A., i, 395.
- Benzoylhydrazobenzene (RASSOW and BAUMANN), A., i, 79.

- allyl ether (v. BRAUN), A., i, 479.
- propyl ether (ZELTZER and TARASOFF), A., i, 316.

- Benzyl mercaptan**, reactions of (SMYTHE and FORSTER), T., 1195; P., 135.
 sulphide *di*bromide (FROMM and RAIZISS), A., i, 555.
*dis*ulphide (SMYTHE and FORSTER), T., 1196.
*tris*ulphide, and its additive compound with silver nitrate (SMYTHE and FORSTER), T., 1196; P., 135.
*tetr*sulphide (SMYTHE and FORSTER), T., 1198; P., 136.
 α-Benzylacetoacetic acid, *o*-cyano-, ethyl ester (MITCHELL and THORPE), T., 2278.
Benzylamine, absorption spectrum of (CURVIS), T., 1552.
Benzylamineacrylic acid. See Methylcinnamic acid, *ω*-amino-.
 1-Benzylaminoanthraquinone (SEER and WEITZENBÖCK), A., i, 371.
 β-Benzylamino-α-benzylcarbamidopropionic acid (FRANKLAND), T., 1689; P., 203.
 4-Benzylamino-*m*-cresol, and its sodium salt and hydrochloride (CHEMISCHE FABRIK AUF AKTIEN FORM. E. SCHERING), A., i, 28.
 4-Benzylaminophenol, 3-chloro- and its hydrochloride (CHEMISCHE FABRIK AUF AKTIEN FORM. E. SCHERING), A., i, 28.
 β-Benzylamino-8-phenyl-α-dimethylpropionic acid, and its salts, ethyl ester, and lactam (STAUDINGER, KLEVER, and KOBER), A., i, 588.
Benzylammonium iridi-chloride and bromide (GUTBIER and RIESS), A., i, 98.
Benzylaniline, spontaneous crystallisation and melting- and freezing-point curves of mixtures of, and azobenzene (ISAAC), A., ii, 1034.
 β-Benzyl-γ-benzylaminomethylhydantoin and its hydrochloride (FRANKLAND), T., 1689; P., 203.
 5-Benzyl-2-benzylideneglyoxalidone (FINGER and ZEH), A., i, 591.
Benzylbutyramide (STAUDINGER, KLEVER, and KOBER), A., i, 587.
 6-Benzylcarbamino-α-naphthol 3-sulphonic acid, and nitro-, sodium salts (BADISCHE ANILIN- & SODA-FABRIK), A., i, 667.
 9-Benzylcarbazole (CASSELLA & Co.), A., i, 775.
 β-Benzylcinnamic acid (RUHEMANS), T., 450.
 4-Benzylconmaran (MARSHALK), A., i, 55.
Benzyldeoxybenzoin, chloro *o*-, *ac*-, and *p*-nitro- (STOBBE and WILSON), A., i, 624.
Benzylidioxindole (KOHN), A., i, 697.
p-Benzyl-*o*-ethylanisole (MARSHALK), A., i, 500.
Benzylethyleonium ferrichloride (SCHOLTZ), A., i, 97.
 Benzyl-*o*-ethylphenol (MARSHALK), A., i, 500.
iso-Benzylglyoxalidone, and its *acetyl* derivative (FINGER and ZEH), A., i, 591.
Benzylhydantoin, *p*-hydroxy-, Bendermann's, synthesis and formation of (DAKIN), A., ii, 796.
Benzylhydrazine, nitroso-, benzyl- and benzenesulphonyl-derivatives of (THELE), A., i, 889.
Benzylidene *dip*ropionate and *dibenz*oate, and *o*-, *m*-, and *p*-nitro-, *dibenz*oates (WEGSCHEIDER and SCHILL), A., i, 155.
Benzylideneacetone semicarbazone, oximinio- (RUPE and KESSLER), A., i, 94.
Benzylidene-*p*-aminobenzoic acid, and *o*- and *p*-hydroxy-, and their esters (MANCHOT and FUDLONG), A., i, 33.
Benzylidenesaminocinnamic acid, *p*-cyano-, amyl ester, optical investigation of (STUMPF), A., ii, 809.
 4-Benzylidenesamino-*m*-cresol (CHEMISCHE FABRIK AUF AKTIEN FORM. E. SCHERING), A., i, 28.
Benzylidenesamino 1-methyltetrahydroquinazoline-2,4-dione, and *o*-hydroxy- (KUNCKELL), A., i, 439.
 4-Benzylidenesaminophenol, 3-chloro- (CHEMISCHE FABRIK AUF AKTIEN FORM. E. SCHERING), A., i, 28.
 3-Benzylidenesaminotetrahydroquinazoline-2,4-dione, and its potassium salt (KUNCKELL), A., i, 439.
Benzylidenesamidine, 3:1-*d*-hydroxy-, and its dimethyl ether (NORLTING), A., i, 177.
Benzylidenesanthranilic acid, and *o*-, and *p*-hydroxy-, 3:4-*d*-hydroxy-, and *o*-, *m*-, and *p*-nitro- (WOLFF), A., i, 736.
Benzylidenesazine, *p*-bromo- and *p*-chloro- (CURTIUS, MELSCH, and RISSON), A., i, 509.
Benzylidene-*o*-*m*-azotoluene-4-hydrazone, and *o*-hydroxy-, and *p*-nitro- (TROGER and WESTERKAMP), A., i, 207.
syn-Benzylidene-5-bromosalicylamide (HUGHES and TITHERLEY), P., 241.
Benzylidenecamphor, 2, 3, and 4-*iso*- (WOOTTON), T., 411.
syn-Benzylidene-5-chlorosalicylamide (TITHERLEY and HUGHES), T., 196, P., 175.

- Benzylidenecinnamylideneacetone**, hydroxylamine-oxime of (CIUSA and BERNARDI), A., i, 684.
- 5-Benzylidene-3- ψ -cinnylrhodanic acid**, and 5-*m*- and *p*-nitro- (KALUZA), A., i, 130.
- Benzylidenedeoxybenzoic acid**, *o*-, *m*-, and *p*-nitro-, and their isomerides and derivatives (STOBBE and WILSON), A., i, 624.
- Benzylidenedioxyphenylpropionic acid**, ethyl ester, isomeride of (DIECKMANN), A., i, 385.
- 4-Benzylidene-3-furyl-5-pyrazolone** (TORREY and ZANETTI), A., i, 892.
- Benzylidene- $\Delta^{1,8}$ -cyclohexadienol** (KÖTZ and GRETHE), A., i, 24.
- 5-Benzylidene-3-isohexylrhodanic acid**, and 5-*m*- and *p*-nitro-, and 5-*o*-hydroxy- (KALUZA), A., i, 131.
- Benzylidenehydrazine**, *o*-amino-, *m*-, and *p*-hydroxy-, and their derivatives (FRANZEN and EICHLER), A., i, 700.
- α -aminobenzylamino-** (CERTEUS, MELERACH, and RISSOM), A., i, 509.
- Benzylidenemethylhydrazine**, nitroso- (THIELE), A., i, 889.
- 4-Benzylidenemethyl-6-methyl-2-pyrimidone**, *m*-*p*-dihydroxy-, and its salts (STARK and BÖGEMANN), A., i, 437.
- Benzylidene-1-phenyl-3-furyl-5-pyrazolone** (TORREY and ZANETTI), A., i, 893.
- benzylidenepiperonylidene γ -pentanones** (STOBBE and HAERTEL), A., i, 44.
- benzylidenepyruvic acid**, oxime of (CIUSA and BERNARDI), A., i, 684.
- benzylidenerrhodanineglycylglycine** (ANDREASCH), A., i, 695.
- Benzoilidene- α -rhodaninepropionic acid**, and *p*-hydroxy- (ANDREASCH), A., i, 695.
- Benzoilidene-1,2:3,4-tetrahydroacridone**, and its picrate (BOESCHE, SCHMIDT, TIEDTKE, and ROTTSEIFER), A., i, 883.
- benzylidene- α -toluidine**, *p*-hydroxy- (MANCOT and FURLONG), A., i, 31.
- benzylidene di- α -tolyl- α -xylylenediamine** (SCHOLZ and WOLFRUM), A., i, 772.
- benzylmalonic acid**, *o*-cyano-, ethyl ester (MITCHELL and THORPE), T., 2270; P., 249.
- Benzyl-8-methylhydrazine**, dihydrochloride and α -nitroso- (THIELE), A., i, 889, 890.
- Benzyl- α -methylhydrazine**, α -nitroso- (THIELE), A., i, 889.
- Benzyl methyl ketone**, α -cyano- (BOUDROUX), A., i, 623.
- 1-Benzyl-2-naphthol-3-carboxylic acid**, and its methyl ester and acetyl derivative, and α -amino-, α -bromo-, α -chloro-, and α -hydroxy-, methyl esters of (FRIEDL), A., i, 742.
- Benzylnitroamine**, and its mercury derivative (THIELE), A., i, 890.
- Benzylloxamic acid**, ethyl ester (THIELE), A., i, 889.
- Benzylloxamide** (THIELE), A., i, 889.
- α - and *p*-Benzylloxybenzoic acid, methyl esters of (COHEN and DUDLEY), T., 1745.
- o*-Benzylloxybenzoyl chloride (BOEHRINGER & SÖHNE), A., i, 386.
- 2-*o*-Benzylloxybenzylloxybenzoic acid** (*benzylloxybenzylloxybenzoic acid*) (BOEHRINGER & SÖHNE), A., i, 386.
- β -Benzylloxynaphthoic acid**, methyl ester of (COHEN and DUDLEY), T., 1748.
- Benzyl pyrrol ketone**, phenylhydrazone (ODD), A., i, 426.
- Benzylsalicylosalicylic acid**. See 2-*o*-Benzylloxybenzylloxybenzoic acid.
- 2-Benzylthiol 5-methyl 6-pyrimidone** (WHEELER, McFARLAND, and STONEY), A., i, 139.
- 1-Benzyl-1,2:3-triazole-4-carboxylic acid**, 5-hydroxy-, methyl ester, and its diazo-derivative (DUMROTH, AICKELIN, BRAHN, FESTER, and MERCKLE), A., i, 520.
- Berberine**, constitution and derivatives of (FALTIS), A., i, 695.
- and allied alkaloids** (PERRIN and ROBINSON), T., 305; P., 21.
- Berberrubine**, and its hydrochloride and sulphate (FRERICHS), A., i, 500.
- Bergamot oil** (SCHIMMEL & Co.), A., i, 757.
- dihydrocinninyl alcohol**, nerol and terpineol in (ELZE), A., i, 495.
- Beri-beri**, the etiology of (KAGIUDA and ROSENHEIM), A., ii, 635.
- Bertrandite**, from Altai (PILIPENKO), A., ii, 48.
- Beryl**, effect of the presence of alkalis on its optical characters (FORD), A., ii, 873.
- from the pegmatites of Madagascar** (DEPARC, WUNDER, and SABOT), A., ii, 312.
- from Blanchaud (Puy-de-Dôme)**, from Montjeu (Saône-et-Loire), (BARBIER and GONNARD), A., ii, 418.
- Betaine**, $C_{12}H_{21}O_2N$, from pyridine and 2-chloro-3:5-dinitrobenzoic acid (ZINCKE), A., i, 556.
- occurrence of**, in the *Chenopodiaceae* (STANĚK and DOMIN), A., ii, 336.

- Betaine**, from the methiodide of benzimidazole-2-benzoic acid (RUPE and THIESS), A., i, 72.
in the tubers of *Helianthus tuberosus* (SCHULZE), A., ii, 534.
verchloate (HOFMANN, ROTH, HÖROLD, and METZLER), A., i, 819.
estimation of (STANĚK and DOMIN), A., ii, 361.
- Betaines**, occurrence of, in drugs containing caffeine and theobromine (POLSTORFF), A., ii, 234.
in plant tissues (SCHULZE and TRIER), A., ii, 743; (ENGLAND), A., ii, 885.
hydroxy-, syntheses of (ROLLETT), A., i, 658, 824.
- Betula alba*, compounds prepared from leaves of (GRASSER and FÜRKERT), A., ii, 440.
- Bile**, influence of, on fat synthesis due to lipase (HAMNIK), A., ii, 427.
and bile salts, influence of, on the movements of the intestine (D'ERRICO), A., ii, 729.
human, secretion of cholesterol in (BACHMEISTER), A., ii, 792.
of seals. See under Seals.
- Bilanic acid**, distillation products of (v. FÜRTH and LENK), A., i, 696.
- Biliary acids**, constitution of the (FREG), A., i, 321.
detection of, in urine (JOLLES), A., ii, 164; (FETTSCH), A., ii, 165.
- Binary mixtures**, investigation of, with an optically active component (SCHEUER), A., ii, 470.
of liquids, physical properties of (HUBBARD), A., ii, 899.
- Binary systems**, energy changes in (KREMANNS), A., ii, 581.
showing mixed crystals, equilibrium in (KEUVR), A., ii, 837.
formed from the alkali sulphates and calcium sulphate (MÜLLER), A., ii, 776.
of the alkali hydroxides, equilibrium curves of (v. HEVEST), A., ii, 835.
organic, molecular compounds in (WROCZYŃSKI and GUYE), A., ii, 699.
application of thermal analysis to (TSAKALOTOS and GUYE), A., ii, 826.
- Biological fluids**, use of invertase in determining the alkalinity or acidity of (HUDSON and SALANT), A., ii, 764.
- Biotoxin**, action of, on blood (MARINO-ZUCO and GIUGANINO), A., ii, 223.
- Bis-3-amino-4-quinazolinone-2-carboxylic hydrazide** (BOGERT and GÖRTNER), A., i, 285.
- endoBisazo-derivatives**, action of sulphuric acid hydrochloric acids on (DUVAL), A., i, 781.
- Bisbenzeneazo-p-diazoaminobenzene** (ONDRORFF and RAY), A., i, 587.
- Bisbromoisovalerylglycerol** (ANDERHALDEN and GUGGENHEIM), A., i, 226.
- 1:2-Biscoumaran-indigo**. See Orindirubin.
- Biscyanosuccinic acid**, thio-, ethyl ester (BENARY), A., i, 581.
- Bis-*o*-diacetylaminocinnamic anhydride** (HELLER and TISCHNER), A., i, 587.
- 1:3-Bisdi-*p*-dimethylaminophenylmethylbenzene**, 4-amido- (REITZENSTEIN and BREUNING), A., i, 441.
- 2:3-Bis(*p*-dimethylaminoanilo)-*a*-hydri-*indone***, hydrate of (RHEIMANN), T., 1445.
- α :8-Bisdiphenyl- α :8-bisdiphenylene-*ethane***, and its peroxide (SCULENK and HERZENSTEIN), A., i, 238.
- Bis-diphenylenemethylene-*p*-phenylenediamine** (REDDELIEN), A., i, 747.
- Bis-diphenylmethylene-*p*-phenylenediamine** (REDDELIEN), A., i, 747.
- Bis-3:6-disulpho-8-naphtholsulphonatolylacetic acid** (HELLER and ANDERKENAS), A., i, 738.
- Bisdithiourethanes**, and their alkyl and piperidine derivatives (BRAUN), A., i, 18.
- Bishydrazodiphenylmethane-4:4-dicarboxylic acid**, and its tetra-acetyl derivative (DUVAL), A., i, 793.
- Bis-5-hydroxy-4-ketophenanthroindithiophen** (AMITZSCH and KELLER), A., i, 419.
- 1:2'-Bis(5-methylcoumaran)-indigo**. See 5:5'-Dimethyloxindirubin.
- Bismite** (SCHALLER and RANSOME), A., ii, 220.
- Bismuth**, spectrum of (SCHWAB), A., ii, 670.
electrolytic refining of (FOERSTER and SCHWAB), A., ii, 819.
- Bismuth alloys** with antimony (PARAVANO and VIVIANI), A., ii, 779.
with cadmium and lead (BARLOW), A., ii, 1066.
with copper and antimony (PARAVANO and VIVIANI), A., ii, 622, 956, 1068.
with lead, analysis of (LUTHE and CAHEN), A., ii, 755.
with tin and lead, separation of bismuth from (SWETT), A., ii, 1064.
- Bismuth benzoates**, (GODFRIN), A., i, 442.
hydrogen iodide as a precipitant of bases (NEUBERG), A., ii, 447.
subnitrate, commercial, estimation of the acid radicle in (HARRISON), A., ii, 352.

- Bismuth peroxides** (GUTHRIE and BÜNZ), A., ii, 303.
- Bismuth**, estimation of, by electrolytic means (BENNER), A., ii, 499.
- 2,4-Bis- α -naphthaleneazoresorcinol**, and its diacetyl derivative (ORNDORFF and RAY), A., i, 597.
- Bis-3-naphtholazodi- α -tolylacetic acid** (HELLER and ASCHKENAST), A., i, 738.
- Bisoxylthionaphthen**, halogen derivatives of (FARBWERKE VOHM, MEISTER, LUCIUS, & BRÜNING), A., i, 410.
- oxidation products of (DANAILA), A., i, 411.
- Bisphenylene-bis- $\beta\beta$ -naphthylenethylene** (THEILE and WASSCHIEDT), A., i, 832.
- Bis- m -phenylenedisulphonylhydroxylamine** (FICHTER and TAMM), A., i, 836.
- Bisphenetoleazobenzaldazinedisulphonic acid**, potassium salt (GREEN and SEN), T., 2247.
- Bisphenetoleazosulphobenzylidenbenzidine**, potassium salt (GREEN and SEN), T., 2247.
- Bisphenetoleazosulphobenzylidenephenylenediamine**, potassium salt (GREEN and SEN), T., 2247.
- Bisphenyl^{iso}oxazolonesoxalic acid**, ethyl ester, and its metallic salts and derivatives (MEYER), A., i, 593.
- Bis-6-sulpho-8-naphtholazodi- α -tolylacetic acid** (HELLER and ASCHKENAST), A., i, 738.
- 3,3-Bisthiobhydantoin** (FRIEDRICH and FÖRSTER), A., i, 191.
- 2,4-Bis- α and p -tolueneazoresorcinol**, and their diacetyl derivatives (ORNDORFF and RAY), A., i, 597.
- 1,6-Bis- α and p -tolueneazoresorcinol**, diacetyl derivatives of (ORNDORFF and RAY), A., i, 597.
- α -Bistriazonoacetoacetic acid**, ethyl ester (FORSTER and NEWMAN), T., 1367; P., 197.
- Bistriazomalonic acid**, ethyl ester and anilide (FORSTER and MÜLLEE), T., 137; P., 4.
- 7-Bistriazonaphthalene** (*naphthylene-2,7-diazine*) (MORGAN and MCKLEHWAIT), T., 2560; P., 293.
- Isoxylenaminodimethylaminotriphenylmethane** (SCHOLTZ and WOLFRUM), A., i, 772.
- Isoxylenaminodiphenylmethane** (SCHOLTZ and WOLFRUM), A., i, 772.
- Isoxylenaminodiphenylstyrylmethane** (SCHOLTZ and WOLFRUM), A., i, 772.
- Isoxylenamino-di- m -tolylmethane** (SCHOLTZ and WOLFRUM), A., i, 772.
- Isoxylenaminotriphenylmethane** (SCHOLTZ and WOLFRUM), A., i, 772.
- Bicret test**, a reagent for the (GIES), A., ii, 763.
- Blackthorn**. See *Eursoria spinosa*.
- Bleaching powder**, action of carbon dioxide and of airon (TAYLOR), T., 2541; P., 242; A., ii, 503.
- Blood**, spectro-photometry of (LETSCHÉ), A., ii, 52.
- adsorption by (MORAWITZ), A., ii, 514.
- cryoscopy of (ATKINS), A., ii, 970.
- the residual carbon of the (MANCINI), A., ii, 727.
- inorganic constituents of (MACALISM), A., ii, 970.
- colouring matter of (KESTER), A., i, 210, 529; (MARCHELEWSKI), A., i, 599.
- phenols in (FILIPI), A., ii, 786.
- concentration of ammonia in, to produce tetany (JACOBSON), A., ii, 988.
- coagulation, a function of calcium salts in (STASSANO and DAUMAS), A., ii, 514.
- in the frog (PRINGLE and TAIT), A., ii, 725.
- in *Gammarus* (TAIT), A., ii, 725.
- composition of, effect of the injection of colloids and crystalloids on the (PUGLIESE), A., ii, 637.
- diastases of, in relation to the pancreas (OLTEN and GALLOWAY), A., ii, 788.
- origin and importance of the amolytic ferment in (MOECKEL and ROST), A., ii, 876.
- oxygen metabolism of the (KROGH), A., ii, 512.
- morphological detection of methemoglobin in (KRONIG), A., ii, 623.
- lipolytic and oxidative processes in, influence of the thyroid glands on (JRSCHTSCHENKO), A., ii, 523.
- neutrality of, the parts played by proteins and hydrogen carbonates in maintaining (ROBERTSON), A., ii, 623.
- poisonous properties of (STUDNINSKI), A., ii, 624.
- tonometry of the gases in the (FIRKET), A., ii, 622.
- transfusion of (BOYCOTT and DOUGLAS), A., ii, 317.
- peritoneal transfusion of (BOYCOTT), A., ii, 725.
- effect of temperature on the dissociation curve of (BAHROFT and KING), A., ii, 50.
- union of oxygen in (MANCINI and BRANDT), A., ii, 137.
- oxygen capacity of, after hemorrhage (DOUGLAS), A., ii, 316.
- and protoplasm, neutrality equilibrium in (HENDERSON), A., ii, 139.
- behaviour of uric acid and its salts in the (GUDZENT), A., ii, 140.

- Blood**, action of biotoxin on (MARINO-ZUCO and GIUGAIXINO), A., ii, 223.
 arterial, tensions of gases in (KROGH and KROGH), A., ii, 512.
 dogs, rotatory properties of the plasma and serum of (ABDERHALDEN and KAWOHL; ABDERHALDEN and HAHN; ABDERHALDEN and RUEHL), A., ii, 1081.
 maternal and foetal, the catalase content of, and the action of foetal serum on animals of the same species (LOCKEMANN and THIES), A., ii, 624.
 normal, autolysis of (SCHIPPERS), A., ii, 1081.
 rabbit's, distribution of reducing substances in (LYTTKENS and SANDGREN), A., ii, 785.
 influence of phloridzin on the sugar in (JUNKERSDOFF), A., ii, 225.
 normal and of animals anaesthetised with chloroform, supposed presence of carbon monoxide in (BUCKMASTER and GARDNER), A., ii, 50.
 chemical tests for (KOBEL, LYLE, and MARSHALL), A., ii, 910.
 reaction of, to silver hydrosol (BREC-CIA), A., ii, 728.
 detection of minute traces of, by means of benzidine (MCWEENEY), A., ii, 84.
 the benzidine test for, and its medico-legal application (WALTER), A., ii, 665.
 the guaiacum test for (KRATZER), A., ii, 684; (BARDACH and SCHNEIDER), A., ii, 664, 911.
 detection of, in urine (FLORENCE), A., ii, 811.
 estimation of adrenaline in (TRENDELBERG), A., ii, 971.
 method of determining alkalinity of (BOYCOTT and CHISOLM), A., ii, 317.
 new apparatus for analysis of gases of (BRODIE; BARCROFT and ROBERTS), A., ii, 342; (BUCKMASTER and GARDNER), A., ii, 727.
 estimation of the quantity of, by the "optical method" (ABDERHALDEN and SCHMID), A., ii, 725.
 estimation of ammonia and urea in (WOLF and MARRIOT), A., ii, 762.
 estimation of dextrose in (OPFLER), A., ii, 463.
 estimation of iron in (CHARNAISS), A., ii, 657.
 estimation of colouring matter and iron in, by a colorimeter (AULEX-METH and KOENIGSBERGER), A., ii, 910.
Blood, estimation of proteins in (WEITZ), A., i, 287.
 estimation of sugar in (BANG, LYTTKENS and SANDGREN), A., ii, 554; (MOECKEL and FRANK), A., ii, 554, 1116; (MICHAELIS and ROSA), A., ii, 660.
Blood-cells of *Limulus*, influence of changes in chemical and physical conditions on the (LOEB), A., ii, 420.
Blood-corpuscles, permeability of, as affected by the substitution of bromine for chlorine in the animal organism (BÖNNIGER), A., ii, 421.
 red, permeability of, to alkali and alkali-earth metals (HANSBUEGLER and BUBANOVIC), A., ii, 1080.
 red, the taking of (BOAF), A., i, 299.
 of the hen, injected into rabbits (McGOWAN), A., ii, 317.
Blood-gases, composition of, in chloroform anaesthesia (BUCKMASTER and GARDNER), A., ii, 1080.
 influence of rise of body temperature on (CASPARI and LOEWY), A., ii, 969.
 of cat (BUCKMASTER and GARDNER), A., ii, 969.
Blood-pigment, compounds of nitric oxide and (MASCHOT), A., ii, 418.
 detection of (SCHTUM), A., ii, 197; (LOCHTE), A., ii, 665.
Blood plasma of dogs, amount of peptolytic ferment in (ABDERHALDEN and FINSCH-SOHN), A., ii, 313, 318; (ABDERHALDEN and ISRAEL; ABDERHALDEN and IMMISCH; ABDERHALDEN and SLEB-WYR; ABDERHALDEN and BRAHM), A., ii, 319.
Blood-platelets, disintegration and life of (DEETJEN), A., ii, 51.
Blood-pressure, action of extracts of the pituitary body on (HAMM DEER), A., ii, 526.
 action of pure choline on (ABDERHALDEN and MÜLLER), A., ii, 530, 726.
 lowering of, by vasolysin (MÜLLER and FELLNER), A., ii, 725.
 arterial, comparative effects of chloroform, alcohol and ether on (WALLER and SYMKE), A., ii, 432.
Blood-serum, anti-substances of, behaviour of, towards solvents and color reagents (KAWAHIMA), A., ii, 140.
 proteins of, influence of anti[?] (CERVELLO), A., ii, 515.
 creatinine in (SCHAFER and REINOLD), A., ii, 731.
 of the horse, albumin from the (MAXIMOWITSCH), A., i, 343.
 of the ox, action of acids and alkalis on the (MORICZ), A., ii, 970.

- Blood stains**, medico-legal examination of, use of benzidine reaction in the (DORDAS), A., ii, 364.
- Blowpipe**, mouth (BAGSTER), A., ii, 892.
- Body**, animal, decomposition and fate of tyrosine in the (DAKIN), A., ii, 796.
- Body-fluids** of normal and immune animals, concentration of anti-substances in (GREER and BECHT), A., ii, 141.
- Boiling-points**, effect of gravity on (SIEPERMANN), A., ii, 267.
determination of (SMITH and MENZIES), A., ii, 687, 688; (HANSEN), A., ii, 827.
estimation of, by Krafft's method (von RECHENBERG), A., ii, 101.
elevation of, under reduced pressure (DRUCKER), A., ii, 929.
and vapour pressures of mixtures of alcohols and water (DOROSCHEWSKY and POLJANSKY), A., ii, 266.
of metals, influence of pressure on the (GREENWOOD), A., ii, 390.
- Boiling-point method**, the Landsberger-Sakurai (TURNER), T., 1184; P., 134.
- Bolus rufus***, occurrence of organic bases in (YOSHIMURA), A., ii, 887.
- Bolognian stones** (*phosphorescent calcium, strontium, and barium sulphide preparations*) (VANINO and ZIMBUSCH), A., ii, 847.
- Bomb**, calorimetric, calibration and manipulation of the (ROTH), A., ii, 584.
analysis by means of a (HIGGINS and JOHNSON), A., ii, 460.
estimation of carbon dioxide by means of the (GRAFE), A., ii, 460.
- Bone**, formation of, part played by the dissociation of carbo-phosphates in the (BARILLÉ), A., ii, 523.
in osteomalacia, analysis of (McCRUDEN), A., ii, 380.
- Bone-marrow**, purine bases of (THAK), A., ii, 141.
lecithin content of (BOLLE), A., ii, 429.
- Bone phosphates**, the nitrogenous substances in (CHARDET), A., ii, 652.
- Borax**. See Sodium tetraborate.
- Boric acid**. See under Boron.
- Borides**, probable chemical nature of, (HOFFMANN), A., ii, 508.
- Borneol**, vapour pressure of (VANSTONE), T., 429; P., 47.
from turpentine oil (FERNÁNDEZ), A., i, 400.
- Borneolglycuronic acids**, isomeric and fusion of (HAYÄLÄINEN), A., i, 326.
- d*-Bornyl-*l*-bornylbenzamidine**, and its derivatives (COHEN and MARSHALL), T., 334.
- d*-Bornyl-*l*-bornylethylbenzamidine**, and its derivatives (COHEN and MARSHALL), T., 335.
- Bornylcamphor** (GUERRET), A., i, 52.
- Bornyleneamphor**, and its hydrobromide and bromo- and nitro-derivatives (GUERRET), A., i, 52.
- Boron**, presence of, in Algerian wines (DUGAST), A., ii, 443.
in Tunisian wines (BERTANCHAND and GAUVRY), A., ii, 646.
colloidal (AGENO and BARZETTI), A., ii, 500.
crystalline (BILTZ), A., ii, 201.
use of, as a catalytic manure (AGULHON), A., ii, 236.
- Boron trichloride**, reduction of, by hydrogen (BESSON and FOURNIER), A., ii, 406.
action of organo-magnesium compounds on (STRICKER), A., i, 532.
- Boric acid**, solubility of (HERZ), A., ii, 275, 407.
detection of, in butter and milk (GAUVRY), A., ii, 156.
estimation of, in plant ashes (BERTRAND and AGULHON), A., ii, 345.
titrimetric estimation of, in silicates (FRONME), A., ii, 351.
- Perborates**, assay of (FAKKAR), A., ii, 452.
- Boron**, detection of minute quantities of (BERTRAND and AGULHON), A., ii, 241.
- Bottle**, for normal solutions and reagents (DAVIS), A., ii, 1105.
- Brain**, chemistry of the (FRÄNKEL and LINNERT), A., ii, 729.
lipoids of the (ROSENHEIM and TERR), A., ii, 1085.
human, sahidin from the (FRÄNKEL and LINNERT), A., i, 295.
analysis of (MASUDA), A., ii, 629.
- Brass**, analysis of, and estimation of tin in (SCHÜRMANN and ARNOUD), A., ii, 519.
estimation of phosphorus in, in the presence of arsenic (SCHÜRMANN), A., ii, 545.
- Brassica juncea**, oil from (SCHIMMEL & Co.), A., i, 759.
- Brassica oleracea**, organic bases in (YOSHIMURA), A., ii, 440.
erepsin from (BLOOD), A., i, 796.
- Bromates**. See under Bromine.
- Bromic acid**. See under Bromine.
- Bromination**, with hypobromous acid (STARK), A., i, 231.
simple apparatus for (BULL and SÄETHER), A., ii, 758.

- Bromine**, addition of, to unsaturated compounds (SUDBOROUGH and THOMAS), T., 715, 2450; P., 294; (ABATI), A., i, 732.
 addition of, to unsaturated compounds, heat liberated on (LUGININ), A., ii, 486.
 absorption of, by lime (WILKS), A., ii, 1063.
 substitution of, for chlorine, with reference to the permeability of the blood-corpuscles (BÜNNIGER), A., ii, 421.
 hydrolysis of (BRAY), A., ii, 819.
 solutions, colour and constitution of (JOSEPH and JINENDRABASA), P., 233.
 water, as a means of distinguishing between aldoses and ketoses (VOTOČEK and NĚMEČEK), A., ii, 463.
Hydrobromic acid (*hydrogen bromide*), dissociation of, at high temperatures (VON FALCKENSTEIN), A., ii, 27, 396.
 heat of combination of, with ethyl-ene compounds (LEGININ and DUPONT), A., ii, 585.
Bromides, compounds of, with mercuric bromide and ether (MARSH), T., 2307.
Bromic acid and hydriodic acid, reaction between, in the presence of a large amount of hydrochloric acid (RANDALL), A., ii, 542.
Bromates, behaviour of, towards reducing agents (VITALI), A., ii, 496.
Bromine, colorimetric estimation of, in the presence of chlorine and iodine (DIBBIN and COOPER), A., ii, 442.
 Weszelsky's method of estimating (CASARES GIL), A., ii, 1107.
 free, gravimetric estimation of, by means of metallic silver (PERKINS), A., ii, 542.
Bromotantalum. See under Tantalum.
Bronze, estimation of phosphorus in, in the presence of arsenic (SCHIRMANN), A., ii, 545.
 analysis of, and estimation of tin, in (SCHIRMANN and ARNOED), A., ii, 549.
Bronzes, corrosion of, in solutions of electrolytes (GIOLITTI and CECCARELLI), A., ii, 217.
 Bolivian, analysis of (LOEB and MOREY), A., ii, 614.
 lead (GIOLITTI and MARANTONIN), A., ii, 504.
 manganese-aluminium (HERSLER and RICHARZ), A., ii, 99.
Broom, common, amount of sparteine in (CHEVALIER), A., ii, 534.
Brownian movement and the real existence of molecules (PERKINS), A., ii, 493.
alloBrucic acid, and its nitrosamine hydrochloride (MOSSLER), A., i, 276.
Brucine, action of, on muscle (VELEY and WALLER), A., ii, 331.
 action of cyanogen bromide on (MOSSLER), A., i, 275.
alloBrucine, and its hydrochloride, methiodide, peroxide^a and oxide (MOSSLER), A., i, 275.
Brucine perchlorate (HOFMANN, ROTH, HOBOLD, and METZLER), A., i, 519.
 peroxide (MOSSLER), A., i, 534.
Brusen flame, photometric measurements with the coloured (BECKMANN and WAENTIG), A., ii, 1.
 inner cone of (HABER and BURDITT), A., ii, 122; (EYSTEIN and KRASA), A., ii, 202.
 the striking back of the (TECUT), A., ii, 705.
Burette, automatic filling (FRAILONG), A., ii, 60; (RAYMOND; ROSE), A., ii, 648.
 without stopcock or rubber connexion, (ALEXANDROFF), A., ii, 747.
 for standard alkali solutions (RUSNICK), A., ii, 893.
Gas Burette, Hempel, modified (GWIGNER), A., ii, 445.
 Winkler-Hempel, modification of (DE KONINCK), A., ii, 648.
Bursaria pinosa (blackthorn), chemical examination of oil from the seeds of (GRIFFITHS), A., ii, 800.
isoButaldehyde, α -bromo-, methylacetal of (ZEISEL and DANIEK), A., i, 92.
cycloButan-1:3 dione, preparation and properties of (CHICK and WHEATZ), T., 1984; P. 217.
Butane, α -chloro- β -bromo- β -hydrazyl (PARISELLE), A., i, 353.
 dinitio- (ANGELI and ALESSANDRI), A., i, 605.
cycloButanecarboxylic acid, *cyclobutyl* carbinyl ester (DEMIANOFF), A., i, 839.
 1-cyano-, ethylester, preparation of (CAMPELL and THORPE), T., 243.
cycloButanehexacarboxylic acid, ethyl ester, synthesis of (SHIBATA), A., i, 851.
Butan- γ -one- $\alpha\alpha\beta\beta$ -pentacarboxylic acid methyl ester (KOMENOS), A., i, 542.
 Δ^2 -Buten- γ -ol, β -bromo-, and its phenylurethane, and $\alpha\alpha\beta$ -tri-iodo- (LESPIERRE), A., i, 149.
 Δ^1 -cycloButen-1-ol-3-one (STAUDINGER and BEREZA), A., i, 90.

- Ac-Buten-γ-one** and its semicarbazone (KRAPIVIN), A., i, 349.
- Butinene-γ-ol** (*methylacetacetylcarbinol*) (LESPIERRE), A., i, 149.
- Butter**, detection of boric acid in (GAUVRY), A., ii, 156.
- estimation of margarine in (RAFFO and FORESTI), A., ii, 360.
- Butter fat**, glycerides of (SIEGFELD), A., ii, 327.
- refraction of the insoluble fatty acids of (DUMITRESCU and POPESCU), A., ii, 556.
- iso*-**Butylacetic acid**, β-imino-α-cyano-, ethyl ester (CAMPBELL and THORPE), T., 1311.
- n*-**Butylacetacetalddehyde**, and its copper salt (COURTIER), A., i, 239.
- Butyl alcohol**, estimation of, in alcoholic liquids (LASSERRE), A., ii, 1005.
- sec*-**Butyl alcohol**, condensation of, with its sodium derivative (GUERRET), A., i, 148.
- iso*-**Butyl alcohol**, conversion of, into α-methylglyceralddehyde (ZEISEL and DANIEK), A., i, 92.
- n*- and *iso*-**Butylammonium** iridi-chlorides and bromides (GUTHRIE and REISS), A., i, 97.
- platinibromides (GUTHRIE and BAURIEDER), A., i, 13.
- Butylbenzene**, 2-chloro- and 3-iodo- (v. BRAUN), A., i, 844.
- tert*-**Butylbenzene**, tetrahydroxy- (HENDERSON and BOYD), T., 1666.
- cyclo*-**Butylcarbinol**. See *Methylcyclobutane*, α-hydroxy-.
- β-Butylcinnamylidenecetic acid**, methyl ester (KÖHLER and HERITAGE), A., i, 485.
- 1-Butylcitronellol** (AUSTERWEIL and COCHIN), A., i, 572.
- tert*-**Butyldihydroisindole**, and its methiodide (SCHOLTZ and WOLFFMUM), A., i, 771.
- 2-*tert*-Butyl-4:5-diphenylpyrrole** (BOON), T., 1260; P., 95.
- β-cyclo*-**Butylformylacetic acid**, α-cyano-, ethyl ester and silver salt of (CAMPBELL and THORPE), T., 2424.
- Butylenebis-3-aminophenyl-α-campthoric acid**, trichloro- (WOOTTON), T., 410.
- Δ⁸-Butylene-γδ-diol**, and its diphenylurethane (PARISELLE), A., i, 463.
- Butylene-αδ dithiol**, and its benzoyl derivative (BRAUN), A., i, 14.
- Δ⁸-Butylene-γ-one-αδδ-tricarboxylic acid**, αδ-*di*bromo-, and its diethyl hydrogen ester (DIELS and REINBECK), A., i, 360.
- 1-*iso*-Butylgeraniol** (AUSTERWEIL and COCHIN), A., i, 687.
- α-*iso*-Butylisohexaldehyde**, its oxime and semicarbazone (FREYRON), A., i, 359.
- dl-iso*-**Butylhydantoic acid** (DAKIN), A., i, 590.
- l-iso*-**Butylhydantoin** (DAKIN), A., i, 590.
- iso*-**Butylidene diacetate** (WEGSCHEIDER and SPATH), A., i, 155.
- iso*-**Butylmalonic acid**, dimethyl and diethyl esters, and its *dichloride* and diamide (FREYRON), A., i, 358.
- 3-*tert*-Butylisoxazole-5-carboxylic acid**, ethyl ester (COURTIER), A., i, 362.
- β-cyclo*-**Butylpropionic acid**, β-imino-α-cyano-, ethyl ester (CAMPBELL and THORPE), T., 2424.
- Butylurethane** and its nitroso-derivative (NIEDLINGER, ACHER, and HEAPE), A., i, 312.
- n*-**Butyric acid**, sodium salt, compound of, with acetic anhydride (ISAKA-LOTOS), A., i, 458.
- n*-**Butyric acid**, α-amino-, derivatives of (HILDESHEIMER), A., i, 891.
- γ-amino-, salts of (ENGELAND and KITSCHER), A., ii, 1090.
- α-bromo-, interaction of, and its sodium salt, with silver salts in aqueous solution (SEXTON), T., 346; P., 23.
- αβ-*di*bromo-, and its ethyl, methyl, and allyl esters, action of bases on (JAMES), T., 1565; P., 201.
- β-hydroxy-, new mode of formation of, in the animal organism (DAKIN), A., ii, 632.
- l*-**Butyric acid**, β-hydroxy-, formation of, in the animal body (DAKIN), A., ii, 976; (FRIEDMANN and MAASE), A., ii, 977.
- iso*-**Butyric acid**, α-benzoylamino-, lactone, anilide and esters (MOHR and GEIS), A., i, 117.
- α-hydroxy-, 1-phenyl-2:3-dimethyl-5-pyrazolone ester (KIEDEL), A., i, 434.
- Butyric acids**, and α- and β-hydroxy-toxic action of, on frog's muscles and nerves (KACZAG), A., ii, 434.
- *dl*- and *d-ay*-*di*hydroxy-, and *dl-β-γ*-*di*hydroxy-, and their salts and derivatives (NRF), A., i, 713.
- iso*-**Butyrylacetic acid**, cyano-, ethyl ester and its silver salt (CAMPBELL and THORPE), T., 1311.
- Butyrylalanine**, ethyl ester (BONDI and ESSLER), A., i, 157.
- β-*iso*-Butyrylbenzylamino-β-phenyl-α-dimethylpropionic acid**, and its silver salt, esters, and derivatives (STAUBINGER, KLEVER, and KOBER), A., i, 587.

O-Butyrylbutyrylacetic acid. See *β* -Butyryloxy- Δ^2 -hexenoic acid.

Butyryl- and isobutyryl-formamide, synthesis of (BARGER and EWING), T., 291; P., 2.

isoButyrylglycine, α -benzoylamino- (MOHR and GEIS), A., i, 117.

α -Butyryl γ - δ -hexene, and its semicarbazone (DARZEN and ROST), A., i, 856.

isoButyrylhydriudone (THIRLE and WEITZ), A., i, 855.

β -Butyryloxy- Δ^2 -hexenoic acid, ethyl ester (LUNIAK), A., i, 90.

Bynia, extraction and reactions of (KRAFT), A., i, 792.

C.

Cabbage. See *Brassica oleracea*.

Cabureibaresinotannol (TSCHIRCH and WEIDMÜLLER), A., i, 689.

Cacodylic acid, amphoteric nature of (HOLMBERG), A., i, 234.

Cacothelin base, coloured isomeric salts of (LEITCH and LEITCH), A., i, 426.

Cadmium, spectrum of (PASCHEN), A., ii, 3, 1014; (HOLDS), A., ii, 87.

normal cell (COHEN and KRYT), A., ii, 259.

and copper, formation of rubenic acid in separation of (BILTZ and BILTZ), A., ii, 456.

equilibrium in the ternary system, lead and mercury (JÄNECKE), A., ii, 699.

behaviour of lithium towards (MASING and TAMMANN), A., ii, 610.

Cadmium alloys with bismuth and lead (BARLOW), A., ii, 1066.

with magnesium and zinc (BRUNI, SANDONNI, and QUERCIGH), A., ii, 954.

with mercury, electro-chemical investigation of (RICHARDS and GARROD-THOMAS), A., ii, 384.

with silver, equilibrium diagram of (BRUNI and QUERCIGH), A., ii, 953.

Cadmium trichromate (GRÖGER), A., ii, 300.

nitrate, hydrates of (VASILIEFF), A., ii, 1060.

sulphide, solubility of, in light petroleum containing oil (VAN DOER and ROSENBERG), A., ii, 126.

Cadmium, use of organic electrolytes in the separation of, from other metals (HOLMES and DOVER), A., ii, 1111.

Cadmium, test for, in the presence of copper (WÖHLER and V. HIRSCHBERG), A., ii, 349.

estimation of, by electrolytic means (BENCKE), A., ii, 999.

Cæcum, of the horse, decomposition of cellulose in the (v. HOESLIN and LESSER), A., ii, 626.

Cæsium, fundamental spectrum of (GOLDSTEIN), A., ii, 869.

ultra-red line spectrum of (PASCHEN; RANDALL), A., ii, 1014.

arseno- and phospho-molybdates (EPHRAIN and HERSCHFINKEL), A., ii, 203.

and rubidium chlorides, relative rates of diffusion in aqueous solutions of (MINES), A., ii, 691.

hydroxide, hydrates of (DE FORTLAND), A., ii, 124.

nitrate solutions, viscosity and density of (MERTON), T., 2454; P., 252.

peroxide, heat of formation of (DE FORTLAND), A., ii, 584.

Caffeic acid, extraction of, from plants (CHABAUX), A., ii, 991.

Caffeine, degradation of (BILTZ and KRENS), A., i, 523.

cardio-vascular effect of, compared with that of green coffee (PACHON and PENHOR), A., ii, 735.

diabetes produced by (SALANT and KNIGHT), A., ii, 735.

nature of the so-called double salts of, with alkali salts (PELLINI), A., i, 416.

compounds of, and sodium benzoate (PELLINI and ANADORI), A., i, 416.

and theobromine, comparative toxicity of (VRELY and WALLER), A., ii, 936.

estimation of, in tea and coffee (BRUMANN), A., ii, 408.

in roasted coffee (VIRCHOW), A., ii, 1011.

in kola (DESIGNES), A., ii, 763.

allo-Caffeine, constitution of (BILTZ), A., i, 522.

apo-Caffeine (1:7 dimethylcafolide, and its silver salt (BILTZ and KRENS), A., i, 523.

Caffeine-phloroglucinol (ULTRA), A., i, 132.

Caffeine-pyrogallol (ULTÉE), A., i, 132.

allo-Caffuric acid (1:3-Dimethylphthaloyl-methylamide, 5 hydroyl-) (BILTZ), A., i, 522.

Calcite, cobaltiferous, from Capo Calmita, Elba (MILLOSEVICH), A., ii, 221.

Calcium, spectrum of, in the oxy-acetylene flame (HENSELECH and DE WATTEVILLE), A., ii, 83.

- Calcium, duration of the rays of, in the spark with self-induction (HEMSLECH), A., ii, 765.
 content in the human organs (MAGNUS-LAVY), A., ii, 426.
 metallic, and absolute alcohol, reduction by (MARSHALL), A., i, 269; (MARSHALL and NICOLAJEWSKY), A., i, 476.
 action of, on organic halides (SPENCER and PRICE), T., 385; P., 26.
 Calcium salts, sparingly soluble, solubility of, in solutions of ammonium salts (RINDELL), A., ii, 294.
 function of, in the coagulation of blood and lymph (STASSANO and DAUMAS), A., ii, 514.
 Calcium manganous bromide (EPHRAIM and MODEL), A., ii, 855.
 carbide, assay of, with the "Decomposition flask" (BERL and JURISSEN), A., ii, 242.
 action of water of crystallisation on (MASSON), T., 851; P., 6.
 carbonate, dimorphism of (LEITMEIER), A., ii, 503.
 thermal dissociation of (JOHNSTON), A., ii, 831.
 colloidal state of (OECHSNER DE CONINCK), A., ii, 612.
 decomposition of (RIESENFELD), A., ii, 126.
 deposition of, from solutions of calcium hydrogen carbonate (VETTER), A., ii, 777.
 chloride and calcium metasilicate, the system (KARANDÉEFF), A., ii, 954.
 zinc chlorides, and iodide (EPHRAIM and MODEL), A., ii, 850.
 ferrites (HILPERT and KOHLMEYER), A., ii, 35.
 fluoride and calcium metasilicate, the system (KARANDÉEFF), A., ii, 954.
 mercuric nitrite (RAY), T., 326; P., 7.
 oxide (*Hinc*), absorption of bromine by (WILKS), A., ii, 1068.
 phosphates (CAMERON and BELL), A., ii, 711.
 solubility of, in saturated solutions of carbon dioxide containing ammonia (FUSIER and NEVILLE), P., 236.
 action of potassium hydroxide on (OECHSNER DE CONINCK), A., ii, 953.
 utilisation of, by *Cruciferae* (RAVENNA and ZAMORANI), A., ii, 741.
 xyalenophosphate (EPHRAIM and MILLER), A., ii, 207.
 metasilicate, binary systems of, with calcium chloride and fluoride (KARANDÉEFF), A., ii, 954.
 Calcium metasilicate, and their absorptive power for nitrogen (KOLB), A., ii, 35.
 silicides (HÖNIGSCHMID), A., ii, 503; (KOLB), A., ii, 1064.
 Calcium sulphate and hydrogen sulphate (ROHLAND), A., ii, 411.
 preparation of the anhydrous modifications of (ROHLAND), A., ii, 125.
 solubility of, at high temperatures (MEISCHER), A., ii, 283.
 solubility of, in solutions of alkali sulphate and free alkali (D'ANS and SCHREINER), A., ii, 849.
 and the alkali sulphates, binary systems formed from (MILLER), A., ii, 778.
 Calcium organic compounds:—
 Calcium cyanamide, efficiency of, as a fertiliser (VANHA), A., ii, 538.
 transformation of, in soil (ULMANN), A., ii, 890.
 and its derivatives (REIS), A., i, 465.
 physiological action of (REIS), A., ii, 801.
 and its decomposition products (STUTZER and REIS), A., ii, 537.
 its analysis and changes in its composition on exposure to the atmosphere (BRIQUET), A., ii, 1010.
 estimation of nitrogen in (STUTZER and SÖLL), A., ii, 1009.
 Calcium, estimation of, in sugar refinery products (SIDERSKY), A., ii, 548.
 and magnesium, separation of (MUNNAN), A., ii, 897.
 separation of, in the presence of phosphates and small amounts of iron (McCRIDEN), A., ii, 243.
 Calcium chloride U-tube, new (MÜLLER), A., ii, 753.
 Calceni, renal. See Renal calceni.
 Callose, new observations on (MANGIN), A., i, 653.
 relation of, to fongose (TANRET), A., i, 654.
 Calorimeter. See under Thermochemistry.
 iso-Calycanthine, from *Calycanthus glaucus* and its salts and nitrosamine (GORDON), A., i, 62.
Calycanthus glaucus, alkaloid of (GORDON), A., i, 62.
 Camidge's reaction (GRIMBERT and BERNIER), A., ii, 163; (STOKEY; ELLENBECK), A., ii, 353; (SCHUMME, HEGLER, and MEYER-WEDELL), A., ii, 468.

- Camphane series**, studies in (FORSTER and ZIMMERLI), T., 2156; P., 245.
- Camphane-oxytriazine**, and its acetyl and benzoyl derivatives (FORSTER and ZIMMERLI), T., 2176.
- Camphene**, occurrence of, in rosin spirit (GRIMALDI), A., i, 273.
- oxidation of, with ozone (HARRIES and PALMEN), A., i, 497.
- Camphenecamphoric acid**. See **Camphenic acid**.
- Camphenic acid** (*camphenecamphoric acid*), constitution of, and α -bromo-, and hydroxy. (ASCHAN), A., i, 709.
- Camphenilone semicarbazone** (HARRIES and PALMEN), A., i, 497.
- Camphor**, vapour pressure of (VANSTONE), T., 429; P., 47.
- and phenol, freezing point curve for mixtures of (WOOD and SCOTT), T., 1573; P., 194.
- synthesis of (KOMPPA), A., i, 51.
- artificial (DABOIS), A., i, 398.
- absorption spectra of the acyl derivatives of (LOWRY and SOUTHWATE), T., 905; P., 68.
- mercury compounds of, action of halogens on (MARSH), T., 2110; P., 297.
- cause of the vanillin hydrochloric acid reaction for (TUNMANS), A., ii, 84.
- Camphor**, bromo-, estimation of bromine in (ANDRE and LÉVELIER), A., ii, 748.
- l*-Camphor, occurrence of, in *Artemisia cana* (WHITTELSKY), A., i, 184.
- Camphor series**, molecular rearrangements in the (NOYES and DERRICK), A., i, 753; (NOYES and KYRIAKIDES; NOYES), A., i, 754.
- α -Camphoramidic acid, alkyl derivatives of (WOOTTON), T., 413.
- d*-Camphorbenzylimide, preparation of (EVANS), T., 2240.
- d*-Camphorbromimide (EVANS), T., 2238.
- Camphorcarboxy-amide**, -chromamide, -piperide, and -bromopiperide (GLOVER and LOWRY), P., 162.
- Camphorcarboxylic acid**, and its derivatives, absorption spectra of (LOWRY, DESCH, and SOUTHWATE), T., 899; P., 68.
- d*-Camphorethylimide, preparation of (EVANS), T., 2240.
- Camphorglycuronic acids**, fission of, by enzymes (HÄMÄLINEN), A., i, 326.
- Camphoric acid**, synthesis of (KOMPPA), P., 328; A., i, 51.
- Komppa's synthesis of (BLANC and THORPE), T., 836; P., 83.
- alkyl and aryl hydrogen esters (EDMUNDSON and HILDITCH), T., 225; P., 10.
- Camphoric acid**, 4,5-*d*-hydroxy-, and its silver and barium salts, and β -bromo. (KOMPPA), A., i, 51.
- Camphoric and isocamphoric acids**, action of the Grignard reagent on esters of (SHIRATA), T., 1239; P., 141.
- π -Camphoric acid, semi-anilide of (KOMPPA), A., i, 51.
- l*-isocamphoric acid, diethyl ester (SHIRATA), T., 1245.
- Camphorimide** *N*-alkyl and aryl derivatives of (WOOTTON), T., 415.
- d*-Camphorimide, preparation of, and its derivatives (EVANS), T., 2237; P., 251.
- d*-Camphoriodimide (EVANS), T., 2239.

- Creatinine (RONA), A., ii, 909.
- in cancerous tumours (SAIKI), A., ii, 146.
- in muscle and blood-serum (SHAFFER and REINOSO), A., ii, 731.
- in urine, effect of the electric bath treatment of the insane on (WALLIS and GOODALL), A., ii, 638.
- separation of, from meat extracts (MICKO), A., ii, 557.
- Crenilabrine (KOSSEL), A., i, 906.
- p-Cresol, 2-bromothio- (ZINCKE and FROHNEBERG), A., i, 315.
- sulphide, and nitro- (GAZDAR and SMILES), T., 2250.
- m-sulphoxide and its dibenzoyl derivative, and nitro-, and its sodium salt (GAZDAR and SMILES), T., 2248.
- o-Cresolarsinic acid, amino-, and nitro- (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 804.
- p-Cresol 5-sulphonic acid, 3-amino-, and 3-nitro-, ammonium salts (SCHULTZ and LOW), A., i, 552.

- Cresotinglyoxydicarboxylic acid**, methyl ester, and its phenylhydrazones (DIMROTH), A., i, 488.
- Critical constants and certain quantities** connected with capillarity, relations between (KLEEMAN), A., ii, 22.
- solution temperature**, properties of solutions at (SCHÜKAREFF), A., ii, 192.
- temperature**, solubilities below and above the (TYRRELL), T., 621; P., 62.
- temperatures and densities**, calculated by means of theory of corresponding states (GOLDHAMMER), A., ii, 270.
- Crotonaldehyde**, bimolecular polymeride of constitution of (DELEPINE), A., i, 218.
- Crotonaldehyde**, α -bromo-, preparation of (VIGNIER), A., i, 461.
- Crotonic acid**, decomposition of, by heating with ammonia (FICHTER and LABHARDT), A., i, 89.
- Crucible**, new platinum lid for (GUTHRIE), A., ii, 343.
- Crucibles**, supports for (ARNDT), A., ii, 747.
- Cruciferæ**, utilisation of tricalcium phosphate by (RAVENNA and ZAMORANI), A., ii, 741.
- Cryoscopic behaviour** of pairs of substances (MASCARELLI and MUSATTI), A., ii, 390.
- determinations** in concentrated solutions (BAUD), A., ii, 268.
- determinations** at low temperatures (BECKMANN, WAENTIG, and NIESCHER), A., ii, 581.
- investigations** of organic mixtures and additive compounds (BUGUER), A., i, 105.
- point of solution**, use of cooling curves in determining the (MOULIN), A., ii, 825.
- Cryptomeria Japonica** oil (KIMURA), A., i, 53.
- Cryptomeriol**, and its xanthic ester (KIMURA), A., i, 51.
- isocryptomeriol** (KIMURA), A., i, 51.
- Cryptopine**, and its salts (PICTET and KRAMERS), A., i, 503.
- Crystal**, solid, influence of the degree of dispersion of α , on its melting point (v. WEIMARN), A., ii, 939.
- Crystals**, formation, equilibrium and alteration of, in an isothermal medium (PAWLOFF), A., ii, 488.
- luminescence** of (LOCCHETTINO), A., ii, 89.
- conduction of electricity** in (DOELTER), A., ii, 818.
- Crystals**, polychroism of artificially coloured (GAUBERT), A., ii, 4.
- pyrognomic**, formation of the crystalline from the amorphous condition on heating (LIEBISCH), A., ii, 489.
- superheating** of (TAMMANN), A., ii, 17.
- liquid**, and Avogadro's hypothesis (LEHMANN), A., ii, 193.
- optics** of (DORN), A., ii, 809.
- self-purification** of (LEHMANN), A., ii, 194.
- mixed**, or solid solutions (Sr. RUŽIČKA), A., ii, 399.
- mixed** and dimorphism, occurring in liquid-crystalline substances (LEHMANN), A., ii, 772.
- stable** only under high pressures (SKRABAL), A., ii, 592.
- Crystalline substances**, transformation of amorphous into (DOELTER), A., ii, 696, 834.
- solid substances**, influence of the degree of dispersion of, on their melting points (v. WEIMARN), A., ii, 1033.
- liquid substances**, magnetic rotation of the plane of polarisation in (VIERA), A., ii, 672.
- and colloidal states**, coexistence of (SCHADE), A., ii, 835.
- Crystallisation** in fused masses, owing to the liberation of gas (RINNE), A., ii, 193.
- from aqueous solutions** (MARO), A., ii, 834.
- and dissolution** in aqueous solutions (LE BLANC and SCHMANDT), A., ii, 276.
- of double salts**, in formation of oceanic salt deposits (ROEKE), A., ii, 290.
- of double sulphates**, influence of substances in solution on the (GERHART), A., ii, 276.
- of tartrate mother liquors**, inertia of (CARLES), A., i, 360.
- Crystallography** and optical properties of organic compounds (BLASS), A., i, 614.
- of compounds** of ethylenediamine (FRANK), A., i, 302.
- of some inorganic compounds** (ZARBONINI), A., ii, 610.
- Crystalloids** and colloids, effect of injection of, on the blood, urinary excretion and lymph (PRELLESI), A., ii, 637.
- Crystal structure**, the relation between, and the chemical composition, constitution and configuration of organic substances (BARLOW and POFF, T., 2308; P., 251).

- Cucurbita citrullus* (water-melon), chemical examination of seeds of (POWER and SALWAY), A., ii, 337.
- Cucurbita Pepo* (pumpkin), chemical examination of seeds of (POWER and SALWAY), A., ii, 338.
- Cucurbitol, and its acetyl derivative (POWER and SALWAY), A., ii, 337.

- test for small quantities of (LOCKEMANN), A., ii, 807.
- nitroprusside reaction for (VAN GIFFEN), A., ii, 1009.

Cyanogen compounds:—

- Hydrocyanic acids**, colorimetric estimation of (CHAPMAN), A., ii, 1119.
 colorimetric estimation of small quantities of (BERL and DELPY), A., ii, 661.
 volumetric estimation of (ROSENTHALER), A., ii, 1119.
 estimation of, in the blood and tissues after death (WALLER), A., ii, 759.
Cyanides, velocity of the transformation of, into leucocyanides (MÜLLER), A., i, 868.
 destruction of (MOIR and GRAY), A., i, 615.
Cyanates, metallic, decomposition of, by water (MASSON and MASSON), A., i, 231.
Cyanogen, volumetric estimation of (GROSSMANN and HÜLTER), A., ii, 349.
Cyanohydrins, racemic, separation of, by emulsion (FEISER), A., i, 402; (ROSENTHALER), A., i, 603.
Cyclic compounds, ultra-violet fluorescence and chemical constitution of (LEY and GRÄFF), A., ii, 563; (LEY and v. ENGELHARDT), A., ii, 813.
 transformation of non-cyclic diketones into (BLAISE and KOEHLER), A., i, 561.
 pinacone transformation in (MEERWEIN and UNKEL), A., i, 856.
Cymene, tetrahydroxy- (HENDERSON and BOYD), T., 1663.
m-**Cymene**, 4-hydroxy-, and its benzoate (FRIES and MOSKOPF), A., i, 384.
Cystins, preparation of (FOLIN), A., i, 606.
Cytolysis, in the unfertilised egg of the sea-urchin (MOORE), A., ii, 975.

D.

- Dacite** from Victoria (WILLINGTON), A., ii, 1078.
Dahlite, probable identity of podolite with (SCHALLER), A., ii, 1076.
Dates, ripening of (VINSON), A., ii, 335.
Datolite from the Lizard district, Cornwall (MCLINTOCK), A., ii, 782.
Datura metel, presence of allantoin in the seeds of (DE PLATO), A., ii, 742.
Daucus carota, oil of the fruit of (RICHTER), A., i, 329.
Dawsonite, a sodium-aluminium carbonate (GRAHAM), A., ii, 136.
Decane, α , α -dibromo-, action of ethyl sodiomalonate on (FRANK and HANKAM), A., i, 460.

- Decane**, α , α -di-iodo-, and its phthalimide and the corresponding phthalimide acid (v. BRAUN and TRÜMPER), A., i, 26.
dinitro- (ANGELL and ALESSANDRI), A., i, 605.
Decane- α -dicarboxylic acid, nitrile of (v. BRAUN and TRÜMPER), A., i, 28.
Decylene oxide, and the corresponding glycol (PRIESCHAEFF), A., i, 86.
Decylene- α -dithiol and its benzoate (v. BRAUN), A., i, 14.
 Δ -**Decylen-8-one** and its semicarbazone (KRAPIVIN), A., i, 349.
Dehydracetic acid, xyleneol from (CARLINFANTI), A., i, 732.
Dehydrocamphenic acid, and its γ -lactone (ASCHAN), A., i, 710.
Dehydrocamphenylic acid (*tricyclic carboxylic acid*), preparation of (BAZDE and MAY), A., i, 32.
Dehydrocholic acid, electrolytic reduction of (SCHENCK), A., i, 10.
Dehydrodicarvacrol, dimethyl ether, diacetate and *di*benzoate (COUSIN and HÉRISSEY), A., i, 476.
Dehydroindogotin-dianilide and *di*-p-tolnide nitrates (GRANDMOUGIN and DESSOULAVY), A., i, 73.
Dehydropentaphenylethanol (SCHMIDLIN and WOHL), A., i, 369.
~~iso~~**Dehydropentaphenylethanol** (SCHMIDLIN and WOHL), A., i, 369.
Dehydroquinacridone (KALE), A., i, 688.
Denitrification in soils and in liquids (KOCH and PETTIT), A., ii, 333.
Density and volume concentration of a solution, relation between (FORQUET), A., ii, 393.
 and optical constants of isomeric organic compounds, relations between the (HEYDRICH), A., i, 765.
 of aqueous solutions of salts, relation between electrical conductivity and (HEYDWEILLER), A., ii, 106.
 of aqueous solutions of salts, relation between degree of dissociation and (TERESCHIN), A., ii, 100.
 of mixtures of propyl alcohol with water (DOROSCHESKY and ROSCHDESTVENSKY), A., i, 85.
 relation between, and refractive index in binary mixtures (SCHWERS), A., i, 813.
Deoxybenzoin, *di*bromo- (BLITZ, EDLERSEN, and SKYDEL), A., i, 570.
Deoxyalcofurfuric acid (1,3-*di*-methyl-*dantol*ylmethylamide) (BLITZ), A., i, 523.
Deprides (FISCHER and FREUDENBERG), A., i, 266.

Diffusion:—

- Osmotic pressure with collodion membranes (MATTHEWS), A., ii, 487.
 relation of, to the intrinsic pressure of liquids (GARVER), A., ii, 935.
 of haemoglobin and laked blood-corpuscles (ROAF), A., i, 209.
 of ionising salts of serum proteins (ROAF), A., i, 344.
 of concentrated solutions of non-electrolytes (SACKUR), A., ii, 273.
 of some plant organs (ATKINS), A., ii, 1100.
Digallic acid (BIGINELLI), A., i, 487.
 and its penta-acetyl, penta-benzoyl and pentaethylcarbonate-derivatives (NIERENSTEIN), A., i, 265.
Digestion and absorption (ARRHENIUS) A., ii, 52; (LONDON; LONDON and RADINOWITSCH; LONDON and DOBROWOLSKAJA; LONDON and SAGELMANN; LONDON and RIVOSCH-SANDBERG; LONDON and DIMITRIEW), A., ii, 422; (LONDON and SCHWARZ; LONDON and GOLMBERG; LONDON and KROCH), A., ii, 972.
 colloidal-chemical aspects of (ALEXANDER), A., i, 530.
 in relation to metabolism (DAHM), A., ii, 1083.
 work of, after carbohydrate food (MÜLLER), A., ii, 1083.
 physiology of (ROSEMANN), A., ii, 1082.
 in new-born infants (IBRAHIM), A., ii, 320.
 in the intestine (BAUMSTARK and CORNHIEIM), A., ii, 518.
 of connective tissue (BAUMSTARK and CORNHIEIM), A., ii, 522.
 pancreatic, influence of bile salts on the, of starch (BUGLIA), A., ii, 627.
 tryptic, influence of sodium glycocholate on (QUAGLIARIELLO), A., ii, 627.
Digestive juices, specific adaptation of (LONDON and LUKIN; LONDON and KRYM; LONDON and DOBROWOLSKAJA), A., ii, 971.
Digitalis and heart muscle extractives (SCHLIOMENSUN), A., ii, 976.
Digitalis group, physiological activity of the (KRAILSHEIMER), A., ii, 530; (MAONUS and SOWTON), A., ii, 986.
Digitalis purpurea, pharmacological activity of the dried leaves of (SCHMIEDEBERG), A., ii, 559.
Digitoxin, estimation of, in foxglove leaves (BURMANN), A., ii, 1010.

- d*. **Diglutaric acid**, α -dihydroxy-, and its disodium salt (NEF), A., i, 113.
1:5-Diglycinoanthraquinone (SEER and WEITZENBÖCK), A., i, 571.
Diglycinoquinone diethyl ester (FISCHER and SCHRADER), A., i, 270.
Diglycinotolquinone, diethyl ester (FISCHER and SCHRADER), A., i, 270.
Diglycollic acid, phenolic esters of (BOHRINGER and SÖHNE), A., i, 732.
 thio-, syntheses with esters of (HINZBERG), A., i, 334.
Digniacolpiperazine (STÉVIGNON), A., i, 781.
Digniacylphosphoric acid and its potassium salt (DUPUIS), A., i, 667.
Digniacylphosphorus chloride and tri-chloride (DUPUIS), A., i, 248.
Diguamide, and its salts and derivatives (RACKMANN), A., i, 896.
Dignanidinoacetic acid, and its salts (RACKMANN), A., i, 897.
Diguandino-oxalic acid, and its salts (RACKMANN), A., i, 896.
Dihexamethylenetetramine cupric and cobalt thiocyanates (CALZOLARI), A., i, 614.
Dicyclohexane, dinitro- (NAMEIRIS), A., i, 829.
Dicyclohexyl as a cryoscopic solvent (MANGARELLI and VECCHIOTTI), A., ii, 1036.
Dihexethylparabanic acid (KALUZA), A., i, 131.
Dihexethylthiocarbamide (KALUZA), A., i, 131.
Dihexethylthioparabanic acid (KALUZA), A., i, 131.
Dihydrazines (V. BRAUN), A., i, 824.
4:4'-Dihydrazinodiphenylmethane, and its derivatives (BORSCHKE and KIENTZ), A., i, 782.
Dihydro-2:4-benzoxazin-1-one-4-acetonitrile, 5:6-dichloro- (BADISCHE ANILIN- & SODA-FABRIK), A., i, 319.
Dihydrobombeeicsterol, and its acetyl derivative (MENZOZZI and MORESE), A., i, 254.
Dihydrobornylene (HENDERSON and POLLOCK), T., 1620; P., 204.
Dihydrocamphene (HENDERSON and POLLOCK), T., 1620; P., 203.
Dihydrocarbostryl-4-carboxylic acid (FICHTER and WALTER), A., i, 98.
d. **Dihydrocarvestrenol** (PERKIN), P., 97.
Dihydrocinnyl alcohol, in bergamot oil (ELZE), A., i, 495.
Dihydrodicamphene (FERNÁNDEZ), A., i, 400.
Dihydroeucantalol (SEMMLER), A., i, 495.

- dihydroeksantallic acid (SEMMLER), A., i, 495.
- dihydrofencholenic acid, its chloride and anhydride (BOUYEAL and LEVALLOIS), A., i, 573.
- dihydroindole, cyano- (v. BRAUN), A., i, 506.
- dihydroindolecarboxylamide (v. BRAUN), A., i, 506.
- 1,4-dihydronaphthalene, absorption spectrum f (LEONARD), T., 1246; P., 143.
- Δ^2 and Δ^3 -dihydro- β -naphthoic acid, methyl esters (RUPE and MÜNTER), A., i, 398.
- Δ^3 -dihydrophenol. See Δ^3 -cyclohexanone.
- dihydrophytosterol, and its acetate (MENOSZI and MORESCHI), A., i, 313.
- Δ^{10} -dihydrovaleric acid (Δ^3 -cyclohexene-2-one-1-carboxylic acid), and its ethyl ester (KÖTZ and GRETHE), A., i, 24.
- Δ^4 -dihydroterephthalic acid, dimethyl ester (RUPE and MÜNTER), A., i, 398.
- α -dihydroxy acids, behaviour of, in the animal body (FRIEDMANN and MAASE), A., ii, 795.
- 2,4-diketo-5-benzylidenetetrahydrothiophen, 3-cyano-, and its sodium and barium salts (BENARY), A., i, 580.
- Diketocamphoric acid, methyl ester and copper salt of (KOMPPA), A., i, 51.
- 3,6-diketo-2,2-diethylpiperazine (ROSENMUND), A., i, 68.
- 2,3-diketodihydro-(1)-thionaphthen, derivatives of (BADISCHE ANILIN- & SODA-FABRIK), A., i, 59, 60.
- 3,6-diketo-2,5-dimethyl-2,5-diethylpiperazine (ROSENMUND), A., i, 68.
- 2,6-diketo-1:3-dimethylpyrimidine, 4-amino- and 5-cyanoacetylamin- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 78.
- 6,8-diketo-2-guanidinopyrimidine, and its salts (RACKMANN), A., i, 896.
- 2,3-diketo-5-methyldihydro-(1)-thionaphthen-2-oxime (BADISCHE ANILIN- & SODA-FABRIK), A., i, 60.
- 6,8-diketo-2-methyl-2-ethylpiperazine (ROSENMUND), A., i, 68.
- 6-diketo-3-methylpyrimidine, 4-amino-5-oxalylamino, and its disodium salt, 4-amino-5-cyanoacetylamin- and 4,5-diamino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 78.
- diketones, aliphatic, reduction of (BLAISE and KOEHLER), A., i, 463.
- non-cyclic, transformation of, into cyclic compounds (BLAISE and KOEHLER), A., i, 561.
- α -diketones, condensation of, with aldehydes and primary arylamines (BOESCHE and TITSINGH), A., i, 65.
- β -diketones, constitution of (SMEDLEY), T., 1484; P., 148.
- 1:2-diketo- Δ^3 -cyclopentene, absorption spectra of derivatives and isomerides of (PURVIS), P., 327.
- 2,4-diketo-6-phenyl-1-benzyl-3:3:5:5-tetramethylpiperidine (STAUDINGER, KLEVER, and KOBER), A., i, 587.
- 4:7-diketo-2-phenyl-4:7-dihydro-2:1:3-benzotriazole, 5-chloro-6-hydroxy- (ZINCKE and SCHARFF), A., i, 141.
- 6:7-diketo-2-phenyl-6:7-dihydro-2:1:3-benzotriazole, 4:5-dichloro- (ZINCKE and SCHARFF), A., i, 141.
- 2,4-diketo-6-phenyl-1:3:3:6:5-pentamethylpiperidine (STAUDINGER, KLEVER, and KOBER), A., i, 588.
- Diketopiperazinobis(α -nitro- p -methylstyryl methyl ketone) (EINHORN and GÖTTLER), A., i, 113.
- 2,6-diketopyrimidine, 5-cyano- (5-cyanouracil), synthesis of, and 5-carboxylamide (JOHNSON), A., i, 69.
- Diketopyrrolone compounds, absorption spectra of (PURVIS), T., 2535; P., 297.
- 2,4-diketotetrahydrothiophen, 3-cyano-, and its silver salt and diacetyl derivative (BENARY), A., i, 580.
- 2,4-diketotetrahydrothiophen-3-carboxylamide, and its potassium salt (BENARY), A., i, 580.
- Dilatometer, for testing gypsum (VAN'T HOFF), A., ii, 348.
- Dilution law, new (PARTINGTON), P., 8.
- Dimereurammonium salts. See under Mercury.
- op*-Dimethoxyacetophenone, ω -chloro- (TUTIN), T., 2512; P., 244.
- mp*-Dimethoxyacetophenone, ω -chloro- (TUTIN), T., 2510; P., 244.
- 4:5-dimethoxybenzaldehydedimethyl-acetal, 2-nitro- (BAMBERGER and ELGAR), A., i, 263.
- 4:5-dimethoxybenzaldoxime, 2-nitro- (BAMBERGER and ELGAR), A., i, 269.
- Di-*p*-methoxybenzenesulphonylhydrazylamine (FICHTER and TAMM), A., i, 836.
- 2,4-dimethoxybenzhydrol (POPE and HOWARD), T., 81.
- 2:3-dimethoxybenzoic acid, 6-nitro-, methyl ester (WEGSCHEIDER and KLENENC), A., i, 672.
- 3:4-dimethoxybenzoic acid, 2:6-dinitro-, methyl ester (WEGSCHEIDER and KLENENC), A., i, 671.
- 4:5-dimethoxybenzoic acid, 2-nitroso-, methyl ester (BAMBERGER and ELGAR), A., i, 269.

- 2:4-Dimethoxybenzophenone, phenyl-, hydrazone and oxime, and its monochloro-derivative (KAUFFMANN and PANNWITZ), A., i, 394.
- 2:4'-Dimethoxy-2-benzoylbenzoic acid, methyl ester (TAMBOUR and SCHÜRCH), A., i, 559.
- 2:4'-Dimethoxy-2-benzylbenzoic acid, and its acid chloride (TAMBOUR and SCHÜRCH), A., i, 559.
- 3:4-Dimethoxy- β -homo- α -methoxy-ethylbenzene (MANNICH and NEUBERG), A., i, 412.
- 4:3- and 5:3'-Dimethoxychalkone, 2:4-dihydroxy-, and diacetyl derivative of the former (MIŁOBEDZKA, v. KOSTANECKI, and LAMPE), A., i, 629.
- 5:2', 5:3', and 5:4'-Dimethoxy-2 cinnamoylphenoxycetic acids, and their ethyl esters (ABELIN and v. KOSTANECKI), A., i, 631.
- Dimethoxycoumaranone (FELIX and FRIEDLÄNDER), A., i, 279.
- 5:6'-Dimethoxycoumaranonyl-1-hydroxy-4-oxynaphthalene (FELIX and FRIEDLÄNDER), A., i, 279.
- 3:3'-Dimethoxy-4:4'-dicarboethoxy- α -diethyl- β -oxazole (MIŁOBEDZKA, v. KOSTANECKI, and LAMPE), A., i, 629.
- 4:4'-Dimethoxydicinnamylethylchloracetalin, and its methyl ether and di-chloride (STRAUS, LUTZ, and HÜSSY), A., i, 564.
- 7:8-Dimethoxy- β -dimethylhexane- β -diol (PURDIE and YOUNG), T., 1534; P., 198.
- pp'-Dimethoxydiphenacylamine hydrochloride (TUTIN), T., 2507.
- pp'-Dimethoxy-2:6-diphenylpyrazine, and its salts (TUTIN), T., 2505; P., 244; (TUTIN and CATON), T., 2531; P., 245.
- pp'-Dimethoxy-2:6-diphenylpyrazine, and its salts (TUTIN), T., 2506; P., 214; (TUTIN and CATON), T., 2532; P., 245.
- 3:4-Dimethoxy-3-ethoxyphenanthrene, and its picrate (PSCHORR and LOEWEN), A., i, 424.
- 3:4-Dimethoxy-8-ethoxyphenanthrene-5-carboxylic acid (PSCHORR and LOEWEN), A., i, 424.
- 3:4-Dimethoxy-8-ethoxyphenanthrene-9-carboxylic acid (PSCHORR and ZEIDLER), A., i, 425.
- 3:4-Dimethoxy-8-ethoxy-5-vinylphenanthrene (PSCHORR and LOEWEN), A., i, 424.
- 5:6-Dimethoxy-1(2')-indexylcoumaranone (FELIX and FRIEDLÄNDER), A., i, 279.
- 4:5-Dimethoxy- α -methylacetophenone, and its phenylhydrazone and semicarbazone (HARDING and WEIZMANN, T., 1128; P., 130).
- 5:6-Dimethoxy-2-methylcoumarone (GRAFFENRIED and v. KOSTANECKI), A., i, 631.
- 6:7-Dimethoxy-2-methyl-1:2-dihydroquinidine, 5(or 8)-nitro- (PYMAN), T., 270.
- 6:7-Dimethoxy-1-methylnaphthalene (LUFF, PERKIN, and ROBINSON), T., 1140; P., 133.
- 1:2-Dimethoxyphenanthrenebenzazine, and its salts (PISOVSKI), A., i, 643.
- 3:6-Dimethoxyphenazonium salts (KEHRMANN and VOGT), A., i, 409.
- 3:6-Dimethoxyphenazonium, methosulphate, chloride, and platinumchloride (KEHRMANN and VOGT), A., i, 409.
- 3:4-Dimethoxyphenylethylamine, and its hydrochloride (MANNICH and JACOBSON), A., i, 168.
- 3:4-Dimethoxyphenylmethylcarbinol, and its acetate, chloride and ethyl ether (MANNICH and NEUMANN), A., i, 412.
- 2:4-Dimethoxyphenylphthalide (TAMBOUR and SCHÜRCH), A., i, 559.
- β -3:5-Dimethoxyphenylpropionic acid, and its amide (SALWAY), T., 217.
- 3:4-Dimethoxyphenylisopropylamine, and its hydrochloride (MANNICH and JACOBSON), A., i, 167.
- 4:4'-Dimethoxyphenylstyrylbromocarbinol, and its methyl ether (STRAUS, KRIEGER, and LUTZ), A., i, 568.
- Di-p-methoxyphenylstyrylchlorobromomethane, and its derivatives (STRAUS, KRIEGER, and LUTZ), A., i, 568.
- 4:4'-Dimethoxyphenylstyrylchloroacetalin, and its methyl ether (STRAUS, KRIEGER, and LUTZ), A., i, 567.
- 4:4'-Dimethoxyphenylstyryldibromomethane, and its derivatives (STRAUS, KRIEGER, and LUTZ), A., i, 568.
- Di-p-methoxyphenyl styryl ketone, and its derivatives (STRAUS, KRIEGER, and LUTZ), A., i, 568.
- 2:5-Dimethoxyphenylthiocarbamide (KAUFFMANN and FRITZ), A., i, 371.
- Dimethoxyphenyl-p-tolylmethane (MCKENZIE), P., 170.
- 2:7-and 2:8-Dimethoxy-9-phenylxanthene-9-ol (v. BAeyer, ARCKEL, DIKHL, HALLENLEBEN and HESS), A., i, 252.
- 3:6-Dimethoxy-9-phenylxanthone-2-carboxylic acid, methyl and ethyl esters, salts of (KEHRMANN and SCHEUNERT), A., i, 407.

- 34 Dimethoxystyrene, ω -bromo- (MAN-
NICH and NEUBERG), A., i, 412.
- Di-*p*-methoxystyrylbromocarbonyl
methyl ether (STRAUS, KRIER, and
LUTZ), A., i, 568.
- Di-*p*-methoxystyryldibromomethane
(STRAUS, KRIER, and LUTZ), A., i,
568.
- 5:2', 5:3', and 5:4'-Dimethoxy-2-styryl-
coumarone (ABELIN and V. KOSTAN-
ECKI), A., i, 631.
- Di-*p*-methoxystyryl ketone, hydrobromide
of (STRAUS, KRIER, and LUTZ),
A., i, 568.
- α -Dimethoxybenzoic acid, its anhydride
and methyl hydrogen ester (PURDIE
and YOUNG), T., 1533.
- α -Dimethoxybenzoyl chloride (PURDIE
and YOUNG), T., 1532.
- 3:4-Dimethoxy-2:2:5:5-tetraphenyl-
tetrahydrofuran (PURDIE and
YOUNG), T., 1535; P., 198.
- 4:5-Dimethoxy- α -toluidine, and its acetyl
derivative (LUFF, PERKIN, and ROBIN-
SON), T., 1134; P., 132.
- 4:5-Dimethoxy- α -tolonitrile (LUFF,
PERKIN, and ROBINSON), T., 1135;
P., 132.
- 4:5-Dimethoxy- α -tolylglyoxylic acid
(HANDING and WEIZMANN), T., 1128.
- 2:4-Dimethoxytriphenylcarbinol
(KAUFFMANN and PANNWITZ), A., i,
394.
- 2:7-Dimethoxyxanthone (v. BAeyer,
AICKELIN, DIEHL, HALLENSELEN,
and HESS), A., i, 252.
- $\alpha\alpha$ -Dimethylacetoacetic acid, γ -bromo-
ethyl ester, condensation of, with
secondary amines (GAULT and
THORPE), A., i, 356.
- 2:5-Dimethylacridine, and its picrate
(BORSCHKE, SCHMIDT, TIEDTKE, and
ROTTERPER), A., i, 882.
- Dimethylacrylic acid, decomposition of,
by heating with ammonia (FICHTER,
LABHARIT and KIEFER), A., i,
89.
- α - and β -Dimethyladipic acids (NOYES
and KYRIAKIDES), A., i, 709.
- N- β -Dimethylisoadrenaline methylene
ether, and its hydrochloride (MANNICH
and JACOBSON), A., i, 414.
- 6:8-Dimethyl-5-allyl- Δ^7 -hepten- γ -one
(HALLER and BAUER), A., i, 220.
- Dimethylamine platinichloride and
periodide, and their use in the separa-
tion of, from trimethylamine (BERTH-
EAUME), A., i, 365.
- p*-Dimethylaminocinnilo- α -hydrindone
(RUFMANN), T., 1446.
- Dimethylaminobenzaldehyde semicarba-
zone (KNÖPPER), A., i, 433.
- α - and *p*-Dimethylaminobenzoic acid,
methyl esters of (COHEN and DUD-
LEY), T., 1746.
- α -4-Dimethylaminobenzoxyloxybenzoic
acid, ethyl ester (EINHORN and v.
BAGU), A., i, 259.
- Dimethylaminobenzylideneanthranilic
acid (WOLF), A., i, 736.
- 5-*p*-Dimethylaminobenzylidene 3- ψ -
cumyl-, and 3-isohexyl-rhodanic acids
(KALITZA), A., i, 130.
- 4-*p*-Dimethylaminobenzylidenemethyl-
6-methyl-pyrimidone, and its hydro-
chlorides (STARK and BÜGEMANN),
A., i, 437.
- β -Dimethylaminobenzylidene- α -rho-
daninepropionic acid (ANDREASCH),
A., i, 695.
- 2-*p*'-Dimethylamino-*p*-cinnamoyl-
phenylidihydroisindole (SCHOLTZ and
WOLFFMANN), A., i, 772.
- Dimethylaminodimethylethylcarbinol,
salts of (FOURNEAU), A., i, 823.
- p*-Dimethylaminodistyryl ketone
(BORSCHKE), A., i, 688.
- γ -Dimethylamino- α -guaiacylpropanol
and its methiodide and benzoyl deriva-
tive (FOURNEAU), A., i, 247.
- Dimethyl- α - β -diaminohexane, derivatives
of (v. BRAUN), A., i, 821.
- γ -Dimethylaminonaphthoxypropanol
and its methiodide (FOURNEAU), A.,
i, 247.
- γ -Dimethylamino- α -*p*-nitrophenoxy-
propanol and its picrate and benzoyl
derivative (FOURNEAU), A., i, 247.
- Dimethylaminocyclooctane, and its de-
rivatives (WILSTÄTTER and WASER),
A., i, 366.
- α -Dimethylaminopentane, and its platin-
chloride and methiodide (WILL-
STÄTTER and WASER), A., i, 366.
- Dimethylaminophenol, perbromide
(WIELAND and WEAVER), A., i,
244.
- γ -Dimethylamino- α -phenoxypropanol,
and its derivatives (FOURNEAU), A.,
i, 247.
- 1-*p*-Dimethylaminophenyl-2:4-dimethyl-
3-hydroxy-methyl-5-pyrazolone
(FARBWERKE VORM. MEISTER, LUCIUS,
and BRÜNING), A., i, 78.
- 1-*p*-Dimethylaminophenyl-2-methyl-3-
hydroxymethyl-4-ethyl-5-pyrazolone
(FARBWERKE VORM. MEISTER, LUCIUS,
and BRÜNING), A., i, 341.
- 1-*p*-Dimethylaminophenyl-2-methyl-3-
hydroxymethyl-5-pyrazolone (FARB-
WERKE VORM. MEISTER, LUCIUS,
and BRÜNING), A., i, 340.
- α - γ -Dimethylaminopropylaniline, and
its salts (v. BRAUN), A., i, 820.

- γ -Dimethylamino α -thymoxypropanol**, and its methiodide (FOURNEAU), A., i, 247.
- γ -Dimethylamino α -p-tolxypropanol**, and its benzoyl derivative (FOURNEAU), A., i, 247.
- Dimethylaminotrimethylcarbinol hydrochloride**, salts of (FOURNEAU), A., i, 823.
- Dimethylammonium iridi-chloride and bromide** (GUTHRIE and RIESS), A., i, 97.
- platinibromide** (GUTHRIE and BAUREDEL), A., i, 12.
- Dimethylamylammonium**, *di-c*-amino-, iodidedihydriodide and other derivatives (v. BRAUN), A., i, 821.
- di-c*-benzoylamino, iodide (v. BRAUN), A., i, 821.
- Dimethylaniline**, absorption spectrum of (PURVIS), T., 1551.
- electrical conductivity of solutions in (SACHANOFF), A., ii, 1027.
- m*-amino-, condensation of aromatic aldehydes with (MOORE), A., i, 280.
- p*-nitroso-, sulphate, compound of hydrogen chloride and (v. KORCZYŃSKI), A., i, 551.
- dithio*- (FICHTER and TAMM), A., i, 836.
- p*-**Dimethylanilineanilphonanilide** (FICHTER and TAMM), A., i, 836.
- Dimethyl-*p*-anisidine**, oxidation of, and its chloride, bromide, *perbromide* and *picrate* (WIELAND and WECKER), A., i, 244.
- 2,6-*d*-nitro- (MELDOLA), P., 232.
- Dimethylanthranilic acid**, *di-c*-cyano- (BADISCHE ANILIN-, & SODA-FABRIK), A., i, 319.
- 1,3-**Dimethylanthraquinone**, 4-amino-, 2,4-*di*-amino-, 4-iodo-, 4-nitro-, and 2,4-*d*-nitro- (SCHOLL and PORSCHNIAUSCHKE), A., i, 272.
- Dimethylbenzocycloheptadienone** (THIELE and WEITZ), A., i, 854.
- Dimethylbenzocycloheptanol** (THIELE and WEITZ), A., i, 855.
- 4,6-**Dimethyl-1:2:3:7:9** benzopentazole (BULOW), A., i, 81.
- 2,6-**Dimethyl-1:3:7:9** benzotetrazole, 4-hydroxy-, and its salts (BULOW and HAAS), A., i, 203.
- 4,6-**Dimethyl-1:3:7:9** benzotetrazole (BULOW and HAAS), A., i, 80.
- Dimethyldibromomaleide** (DIELS and REINBECK), A., i, 360.
- Dimethyl-brown**, a new indicator (POZZI-ESCOTT), A., ii, 153.
- Dimethyl-*tert*-butylethylene glycol** (PRIESCHAREFF), A., i, 86.
- γ -Dimethyl- γ -isobutylhexan β -ol** (FREY-LON), A., i, 359.
- β -Dimethyl- γ -isobutyl Δ^2 -hexene** (FREY-LON), A., i, 359.
- $\alpha\beta$ -Dimethylbutyric acid**, α -hydroxy-, 1-phenyl-2,3-dimethyl-5-pyrazolone ester (RIEDEL), A., i, 434.
- 1,3-**Dimethylcaffolide** (BLITZ and KNEBS), A., i, 521; and its silver salt (BLITZ), A., i, 522.

- of solvents (WALDEN), A., ii, 264.
- of the halogen hydrides (SCHAEFER and SCHLUNDT), A., ii, 12.
- Dielectric properties of the elements (DOBROSERDOFF), A., ii, 93.

ELECTROCHEMISTRY:—

- Cathode potential** fall at a potassium electrode in argon (GEHLHOFF), A., ii, 571.
- Cathodic volatilisation** (KOHLSCHÜTTER), A., ii, 96.
- Electrode**, hydrogen, abnormal action of the (ENKLAAR), A., ii, 819.
- iron (FOERSTER and HEROLD), A., ii, 570.
- oxygen (GRUBE), A., ii, 926.
- potassium, in argon, cathode fall of potential, at a (GEHLHOFF), A., ii, 571.
- sodium, potential of the (LEWIS and KRAUS), A., ii, 1027.
- thallium, potential of the (LEWIS and ENDE), A., ii, 571.
- potentials, and electrochemical reactions (KISTIAKOWSKY), A., ii, 258.
- Electrolysis**, investigation of, with the ultramicroscope (KOSONOGOFF), A., ii, 97.
- of molten salts (LORENZ), A., ii, 179; (KAILAN), A., ii, 928.
- of alkaline-earth iodides (v. HEVESY), A., ii, 928.
- of solutions of inorganic salts in formamide (RÖHLER), A., ii, 684.
- separation of metals by (BUCKMINSTER and SMITH), A., ii, 1112.
- Electrolytes**, conductivity and ionisation of, in aqueous solutions (CLOVER and JONES), A., ii, 256.
- ionic equilibrium in solutions of (PARTINGTON), T., 1158; P., 114.
- condensation of water by (CAMERON and ROBINSON), A., ii, 188, 692.
- the solubility influence of (HEEZ), A., ii, 711.
- relations between the freezing-point depression, ionic concentration, and conductivity of (GOEBEL), A., ii, 268.
- action of aqueous solutions of, on germination (MICHELS), A., ii, 232.
- amphoteric, hydrolysis of salts of (BEVERIDGE), A., ii, 25.
- Electrolytic dissociation** of fused salts (LORENZ), A., ii, 259.
- and conductivity of organic acids (WHITE and JONES), A., ii, 821.
- Electrolytic processes**, oscillographic investigation of (REICHENSTEIN), A., ii, 1028.
- Electro-syntheses** (LOSANITSCH), A., i, 1, 542.
- Electromotive force**, calculation of, from thermal measurements (MAGNUS), A., ii, 581.

ELECTROCHEMISTRY:—

- Electron theory**, and solid solutions of metals (SCHENCK), A., ii, 482.
- Electrons**, number of, in an atom, (CROWTHER), A., ii, 918.
- bound, behaviour of, towards electromagnetic radiation (KOENIGSBERGER and KILCHLING), A., ii, 679.
- free, occurrence of, in chemically inert gases (FRANCK), A., ii, 817.
- negative, emission of, by alkali metals (DUNOYER), A., ii, 253, 572.
- Ionisation** produced by α -rays (WHEELLOCK), A., ii, 1021.
- produced by an α -particle (KLEEMAN), A., ii, 92; (GEIGER), A., ii, 473.
- produced by the splashing of mercury (LONSDALE), A., ii, 922.
- by chemical action and by splashing (BLOCH), A., ii, 381, 480.
- by bubbling and chemical action (DE BROGLIE and BRIZARD), A., ii, 480.
- by Röntgen rays (BARKLA), A., ii, 920.
- and chemical action (REBOUL), A., ii, 822.
- and conductivity of acids, bases and salts in aqueous solutions at high temperatures (NOYES, MELCHER, COOPER, and EASTMAN), A., ii, 257.
- of electrolytes in aqueous solutions (CLOVER and JONES), A., ii, 256.
- of air by the carbon monoxide flame and by radium emanation (DE BROGLIE), A., ii, 570.
- the effect of dust and smoke on the (EVE), A., ii, 479.
- of salts in mixtures with no common ion (SHERRILL), A., ii, 570.
- of gases (METCALFE, DE BROGLIE, and BRIZARD), A., ii, 11.
- by the cathode rays ejected by X-rays (KLEEMAN), A., ii, 567.
- by the β -rays of actinium (KLEEMAN), A., ii, 474.
- through mechanical division of liquids (DE BROGLIE), A., ii, 480.
- of the nitrites, measured by the cryoscopic method (RAY and MUKHERJEE), P., 173.
- of the hot spring of Hamman-Salahin, near Biskra (NODON), A., ii, 478.
- constants, tables of (LAEVY), A., ii, 814.

ELECTROCHEMISTRY:—

- Ionic concentration**, of hydrogen and hydroxyl in placental and retro-placental serum (LÖB and HIGUCHI), A., ii, 326.
- Ionic equilibrium** in solutions of electrolytes (PARTINGTON), T., 1153; P., 114.
- Ions**, adsorption of (BOURNAT), A., ii, 103.
- selective absorption of, by roots (PANTANELLI and SELLA), A., ii, 149.
- neutralisation of, produced in chemical reactions (PROUTEN), A., ii, 381, 479.
- rate of migration of (RIESENFELD and REINHOLD), A., ii, 14; (DENISON), A., ii, 15.
- emitted by hot substances, specific charge of (RICHARDSON and HULBERT), A., ii, 923.
- hydration and molecular heat of, in very dilute aqueous solutions (MIE), A., ii, 822.
- analogous to those of Röntgen rays in gases derived from hydrogen flames (DE BROGLIE), A., ii, 769.
- electrolytic, theory of (LORENZ), A., ii, 577.
- gaseous, diffusion of (SALLÉS), A., ii, 1024.
- large, in the air, mobility of (LUSBY), A., ii, 10; (POLLOCK), A., ii, 11.
- Potential** of chlorine, bromine and iodine in methyl and ethyl alcohol (NEUSTADT), A., ii, 1028.
- of the system silver-silver acetate, influence of dissolved gases on the (JAQUES), A., ii, 383.
- oxidation of iron oxalates and of the oxalate ion (SCHAPER), A., ii, 380.
- Potentials**, decomposition (BENNEWITZ), A., ii, 385.
- Potential differences** at the contact of two electrolytes (PLEYEL), A., ii, 386.
- "Transfer resistance" in "reversible" electrolytic metal decomposition (SAND and BLACK), A., ii, 259.
- Transport numbers**, determination of (RIESENFELD and REINHOLD), A., ii, 14; (DENISON), A., ii, 15; (LEWIS), A., ii, 683.
- Transport phenomena** in solutions of colouring matters (VIGNON), A., ii, 483.
- Voltmeter**, water, migration of ions in the (STREINTZ), A., ii, 923.
- Electric vacuum furnace** (RUFF), A., ii, 575.

Electrolytes. See under Electrochemistry.

Electron theory. See under Electrochemistry.

Elements, distribution of the, in the earth's crust (VERNANSKY), A., ii, 1013.

genetic connexions between the (MOIR), A., ii, 491.

atomic volumes of, before and after combination (PRIDEAU*), T., 2032; P., 207.

thermo-magnetic properties of the (BOIS and HONDA), A., ii, 453; (HONDA), A., ii, 686.

dielectric properties of the (DOBRONOFF), A., ii, 93.

periodicity of the properties of (TOCHER), A., ii, 773.

and the part remaining in combinations, energy of (QUARTAROLI), A., ii, 491.

Elephant, pancreas of the (FERNANDEZ), A., ii, 427.

Ellagic acid, preparation of (BUSCHUEFF), A., i, 117; (TRUNKEL), A., i, 389.

Ellagitannic acid, preparation of (NIERENSTEIN), A., i, 389.

Emission spectra. See Spectra under Photochemistry.

Emulsin, non-identity of, with cellulase (BERTRAND and COMPTON), A., i, 500.

hydrolysis of amygdalin by (ROSENTHALER), A., i, 403.

hydrolysis of salicin by (HUTSON and PAINE), A., i, 83.

resolution of racemic cyanohydrins by (FRIST), A., i, 402; (ROSENTHALER), A., i, 603.

enzymes of (ARMSTRONG and HORTON), A., i, 602.

rapid detection of (ARMSTRONG), A., ii, 668.

Emulsin (ROSENTHALER), A., i, 800.

Emulsions (OSTWALD), A., ii, 194.

clearing of (FANTO and SERRA), A., ii, 600.

of oil and water, constituents of (ROBERTSON), A., ii, 697.

Enantiomorphous substances, distillation of mixtures of (EVANS), T., 2236; P., 251.

Enargite, from Ouray Co., Colorado (THORNTON), A., ii, 418.

Energy. See under Affinity, chemical.

Enterolipase (JANSSEN), A., ii, 830.

Enzymatic processes, measurement and meaning of the concentration of the hydrogen ions in (SØRENSEN), A., i, 147.

action of poisons on (SANTESON), A., ii, 331.

Enzyme, diastatic, in leucocytes (HABER-LANDT), A., ii, 515.
 capable of splitting cholesterol esters, does the liver contain an? (KONDO), A., ii, 791.
 peptide-splitting, of ovaries (KORLENCK and LÖB), A., ii, 1088.
 Enzymes, studies on (SØRENSEN), A., i, 147.
 chemical composition and formation of (EULER and AF UGGLAS), A., i, 345, 796.
 study of, by means of the synthetical polypeptides (KOELKER), A., i, 794.
 cataphoresis of (ISCOVESCO), A., i, 290.
 the protective action of proteins on (ROSENTHALER), A., i, 600.
 inactivation of, and formation of anti-substances in the presence of colloidal (PORTER), A., i, 600.
 asymmetric syntheses by means of (ROSENTHALER), A., i, 603.
 capable of splitting asparagine, distribution of, in the organs (V. FÜRTH and FRIEDMANN), A., ii, 733.
 and poisons (BYWATERS and WALLER), A., ii, 736.
 in bacteria (ABDERHALDEN, PINCUS-SOHN, and WALTHER), A., ii, 989.
 of diastase (LJALIN), A., i, 907.
 of emulsin (ARMSTRONG and HORTON), A., i, 602.
 of gum-acacia and other gums (GrafE), A., i, 143; (REINITZER), A., i, 290.
 of malt, filtration of (HOLDERER), A., i, 212.
 of the mammary gland (GRIMMER), A., i, 325.
 of milk (SÄRTHOU), A., ii, 326; (MEYER; GERBER), A., ii, 527; (WOHLGEMUTH and STRICH), A., ii, 633.
 of boiled milk, coagulation of fresh milk by (GERBER), A., ii, 633.
 from muscle (RANSOM), A., ii, 524.
 of nuclein metabolism (SCHITTENHELM), A., ii, 52.
 of pancreatic juice, action of heat on the (Visco), A., i, 603.
 amount of, in dog's blood plasma (ABDERHALDEN and PINCUSOHN), A., ii, 313, 319; (ABDERHALDEN and IMMISCH; ABDERHALDEN and ISHAEL; ABDERHALDEN and SLEESWYK; ABDERHALDEN and BRAHM), A., ii, 319.
 acting on disaccharides in the human embryo and new-born child (IBRAHIM; IBRAHIM and KAUMHEIMER), A., ii, 629.
 autolytic, behaviour of α -leucyl-L-tryptophan towards (FISCHER), A., i, 599.

Enzymes, inorganic (BREDIG and SOMMER), A., ii, 284.
 intracellular, detection of (ABDERHALDEN and PRINGSHEIM), A., ii, 437.
 nuclein, extracts of, relation of, to physiological phenomena in the living organisms (JONES), A., ii, 526.
 oxidising, preparation of, from plant extracts (BACH), A., i, 291.
 fat-splitting and oxidising, of the thyroid glands (JITSCHTSCHENKO), A., ii, 526.
 peptolytic, detection of, in animal and vegetable tissues (ABDERHALDEN), A., ii, 665.
 in cancer and other tumours (ABDERHALDEN and MEDIGRECHANU; ABDERHALDEN and PINCUSOHN), A., ii, 638.
 proteolytic (HIRAYAMA), A., i, 449.
 action on protamines (TAKEMURA), A., i, 82.
 perine, of guinea-pig and rabbit (MITCHELL), A., ii, 731.
 estimation of, in the faeces (URY), A., ii, 145.

- α 2'-Ethoxyphenyl-2-nitro-3:4-dimethoxybenzoic acid (PSCHORR and ZEIDLER), A., i, 425.
- 2-Ethoxy- β -phenylpropionic acid, α , β -bromo-5-nitro-, methyl ester (CLAYTON), T., 2110.
- p*-Ethoxyphenylpyrocinehonamic acid, *p*-phenetidine salt of (PIUTTI and ABATI), A., i, 674.
- p*-Ethoxyphenylpyrocinehonimide (PIUTTI and ABATI), A., i, 674.
- 7-Ethoxy-3-phenylpyrazoquinazoline (MICHAELIS and LEO), A., i, 515.
- p*-Ethoxyphenylterephthaldiamide (PIUTTI, PUGLIESE, and SELVAGGI), A., i, 676.
- Ethoxypiperonylideneepinacoline, α - and β -, and bromo- (HOON and WILSON, T., 1755; P., 208).
- Ethoxyquinolineazophenol (FOX), T., 1347.
- Ethoxytriphenylallyl alcohol (REV-NOLDS), A., i, 859.
- Ethyl alcohol, first synthesis of (MADOLA), A., i, 533.
- apparatus for preparation of absolute (WARREN), A., i, 359.
- and water, molecular compounds of (FAWCKETT), A., i, 533.
- and water, refractive indices of mixtures of (SIDENSKY), A., ii, 756.
- and acetaldehyde, the system, SMITH and DE LEEUW, A., i, 816.
- and sulphuric acid, equilibrium in the reaction between (ARENASSY), A., ii, 790.
- production of formaldehyde in the oxidation of (VOISENET), A., i, 91.

- Ethyl alcohol, influence of, on metabolism (MENDEL and HILDTON), A., ii, 223.
 influence of, on the quantity of phosphatides in animal organs (SIEBER), A., ii, 147.
 ether and chloroform, comparative effects of, on blood-pressure (WALLER and SYMES), A., ii, 432.
 detection of, in the presence of methyl alcohol (DENIGES), A., ii, 1115.
 detection of methyl alcohol in (DENIGES), A., ii, 461.
 toxicological detection of (LECCO), A., ii, 461.
 estimation of (SIDERSKY), A., ii, 161.
 estimation of aldehydes in (RONNET), A., ii, 663.
 estimation of ethyl ether and benzene in (WOLFF), A., ii, 1116.
 Ethyl ether, kinetics of the formation of (KREMAN), A., ii, 945.
 preparation of (SENDERENS), A., i, 649.
 critical phenomena of (YOENG), A., ii, 1032.
 drying of moist (v. SIEBENROCK), A., i, 150.
 solubility of, in water (OSAKA), A., i, 649.
 and sulphuric acid, physical properties of mixtures of (POUND), F., 311.
 action of, on the circulation (EMBLEY), A., ii, 228.
 anthraquinone and naphthalene, critical phenomena of the system (FRINS), A., ii, 1050.
 compounds of, with mercuric halides and halogen salts (MARSH), T., 2305.
 chloroform and alcohol, comparative effects of, on blood-pressure (WALLER and SYMES), A., ii, 432.
 estimation of, in alcohol (WOLFF), A., ii, 1116.
 Ethyl nitrate, condensation of, with *o*-bromophenylacetonitrile (WISLIZENUS and FISCHER), A., i, 621.
 barium sulphate, decomposition of, in acid and alkaline solution at different temperatures (KREMAN), A., ii, 596.
 2-Ethylaminobenzoic acid, 4-iodo- (WHEELER and JOHNS), A., i, 843.
 5-iodo- (WHEELER and JOHNS), A., i, 381.
p-Ethylaminobenzoic acid, and its acetyl and chloroacetyl derivatives (HOUBEN and FREUND), A., i, 111.
 4-Ethylamino-5-keto-2:2:4-trimethyl-tetrahydrofuran, and its phenylcarbamide and nitroso-derivative (KOHN and BUM), A., i, 137.
 2-Ethylaminomesitylenic acid (WHEELER and HOFFMAN), A., i, 666.
 4-Ethylamino-2:2:3-trimethyl-1-ethyl-5-pyrrolidone (KOHN and BUM), A., i, 137.
 4-Ethylamino-*m*-toluic acid (HOUBEN, SCHOTTMÜLLER, and FREUND), A., i, 35; (WHEELER and HOFFMAN), A., i, 666.
 6-Ethylamino-*m*-toluic acid (HOUBEN, SCHOTTMÜLLER, and FREUND), A., i, 35.
 Ethylammonium indid-chloride and bromide (GUTHRIE and RIESS), A., i, 97.
 platinumbromide (GUTHRIE and BAURIEDL), A., i, 12.
 Ethylaniline, absorption spectrum of (PURVIS), T., 1551.
 2:4:5-trinitro- (VAN ROMBURGH), A., i, 20.
 3-Ethylanilinomethyl 1-phenyl 4:4-dimethylpyrazolone (GAULT and THIÉRODE), A., i, 357.
 γ -Ethylanilino- α -dimethylacetoacetic acid, ethylester (GAULT and THIÉRODE), A., i, 357.
 Ethylanilinomethyl *isopropyl* ketone, and its phenylhydrazones (GAULT and THIÉRODE), A., i, 357.
 Ethylbenzene, *o*- and *p*-iodo-, and their derivatives (SCHREINER), A., i, 467.
 α : β : γ : δ : ϵ pentabromo-2-hydroxy-, and its acetyl derivative (FRIES and MOSKOPF), A., i, 332.
 2-Ethylbenzimidazole 5-carboxylic acid, methyl ester and derivatives (EINHORN and UHLFELDER), A., i, 173.
 Ethylbenzo-*ycloheptadienone* (THIELE and WEITZ), A., i, 854.
 α -Ethylbutyric acid, α -bromo-, α -amino-, α -chloroacetylamino- and α -glycylamino- (ROSENEMUND), A., i, 63.
 α -hydroxy-, 1-phenyl-2:3-dimethyl-5-pyrazolone ester (RIEDEL), A., i, 434.
 Ethylbutyrylaminoacetic acid, bromoethyl ester (ROSENEMUND), A., i, 63.
 Ethylbutyrylglycinamide, bromo- (ROSENEMUND), A., i, 69.
 β -Ethyl- ψ -carbamidoacrylethyl- ψ -thiocarbamido- α -cyano- (JOHNSON), A., i, 69.
 6-Ethylcarbamino- α -naphthol-3-sulphonic acid, sodium, and barium salts (BADISCHE ANILIN- & SODA-FABRIK), A., i, 657.
o-Ethylcarbonatobenzoic acid, anhydride of (EINHORN and v. BAGH), A., i, 260.
p-Ethylcarbonatobenzoic acid, and its chloride (FISCHER and FREUDENBERG), A., i, 266.
o-Ethylcarbonatobenzoyl chloride (EINHORN and v. BAGH), A., i, 260.

- o-Ethylcarbonatobenzoyl-p-aminobenzoic acid, ethyl ester of (EINHORN and v. BACH), A., i, 260.
- o-Ethylcarbonatobenzoylanthranilic acid, methyl ester of (EINHORN and v. BACH), A., i, 260.
- 2-o-Ethylcarbonatobenzoyloxybenzoic acid (*ethylcarbonatobenzoylethylbenzoic acid*) (BOEHRINGER & SÖHNE), A., i, 386.
- p-Ethylcarbonatobenzoyloxybenzoic acid, and its chloride (FISCHER and FREUDENBERG), A., i, 266.
- Ethyl carbonatobutyronitrile (DANIS), T., 951; P., 90.
- Ethylcarbonatodi-p-oxybenzoyl-p-oxybenzoic acid (FISCHER and FREUDENBERG), A., i, 266.
- Ethylcarbonatotri-p-oxybenzoyl-p-oxybenzoic acid (FISCHER and FREUDENBERG), A., i, 266.
- Ethylcarbonatobenzoylethylbenzoic acid. See 2-o-Ethylcarbonatobenzoyloxybenzoic acid.
- Ethyl trichloroethyl ether (CONSORTIUM FÜR ELECTROCHEMISCHE INDUSTRIE), A., i, 650.
- Ethyleinchotoxol, salts and derivatives of (COMANDECCI), A., i, 582.
- Ethyleinchotoxile, chloro-, and its picrate and platinumchloride (COMANDECCI), A., i, 583.
- 1-Ethylironchloral (AFSTERWEIL and COCHIN), A., i, 572.
- 2-Ethyl 3,4-dihydroisoquinolinium, 6,7-dihydroxy-, hydroxide, phenol-betaine, and derivatives of (LYMAN), T., 280.
- Ethylidithiocarbamic acid, chloromercuric salt (ANSCHÜTZ), A., i, 158.
- Ethylene, preparation of (SENDERENS), A., i, 649.
- theory of the formation of (KREMAN), A., i, 458.
- cuprous compounds of (MANCHOT and BRANDT), A., i, 85.
- derivatives, stereoisomeric, conversion of stable into labile modifications, by ultra-violet light (STOERMER), A., i, 114.
- Ethylene, chloro-derivatives, additive compounds of (HOFMANN and KIRMREUTHER), A., i, 3.
- trichloro-, physical and physiological properties of (VELEY), A., i, 214.
- uses of, in analytical chemistry (GOWING-SOUPES), A., ii, 647.
- chloro-tri-iodo- (HOFMANN and KIRMREUTHER), A., i, 16.
- Ethylene glycol, electrolysis of (LÖB and FULYRMACHER), A., i, 94.
- Ethylenediamine, compound of, crystallographic properties of (FRANK), A., i, 302.
- Ethylenediamine perchlorate (HOFMANN, ROTH, HÖBOLD, and METZLER), A., i, 818.
- Ethylenediammonium iridi-chloride and bromide (GUTHRIE and RIES), A., i, 98.
- platinibromide (GUTHRIE and BAURIEDL), A., i, 13.
- Ethyleneguanidine. See Tetrahydroglyoxaline, 2-imino-.
- Ethylenic compounds, stereoisomeric transformation of (PFEIFFER and LANGENBERG), A., i, 810.
- 1-Ethylglyoxaline, 2:4:5 tri-iodo- (PAULY), A., i, 839.
- 4-Ethylglyoxaline, β -amino-, and other active principles of ergot (BARBER and DALE), T., 2592; P., 327; A., ii, 736.
- and an ergot base, physiological actions of (ACKERMANN and KERNIGER), A., ii, 881.
- Ethyl hydroxy-sec-butyl ketone (BLAIR and HERMAN), A., i, 534.
- Ethylidene dibenzoate (WEGSCHEIDER and STÄHL), A., i, 156.
- syn. Ethylidenesalicylamide (HICKS), T., 1034; P., 91.
- Ethyliminothiocarbonic acid, dimethyl ester, and its picrate (DEKLEPNE), A., i, 613.
- 3-Ethylindole, β -amino-, syntheses of (EWINS and LAIDLAW), P., 343.
- Ethylketenecarboxylic acid, ethyl ester (STÄPPLINGER and BEREZA), A., i, 59.
- Ethylmalonic acid, and bromo-, chlorides of ethyl esters, and anilide (STÄPPLINGER and BEREZA), A., i, 90.
- Ethylmalonylbis-hydrazonoacetoacetic acid, ethyl ester (BULOW and BOZENHARDT), A., i, 103.
- Ethylmalonylbis-hydrazide (BULOW and BOZENHARDT), A., i, 103.
- 4- and 6-Ethylnitrosoamino-m-toluidic acid (HOFEN, SCHOTTMÜLLER, and FREUND), A., i, 35.
- 7-Ethylpentane, γ -chloro- (SCHREINER), A., i, 661.
- α -Ethyl- Δ^8 -pentenoic acid, and its barium salt (FICHTER and ORLADEN), A., i, 87.
- β -Ethyl- Δ^8 -pentenoic acid, transformation of into β ethylvalerolactone, and ethyl ester and toluidide of (FICHTER, KIKER, and BERNOLLI), A., i, 88.
- α -Ethylpropylmalonic acid, ethyl ester (REYNOLDS), A., i, 858.
- β -Ethyl- ψ -thiocarbamidoacrylic acid α -cyanooethyl ester (JOHNSON), A., i, 89.
- Ethyl- ψ -thiocarbonatoacetanilide (HOFMANN and PSILANDREHME), A., i, 834.

Ethyltrithiocarbonatoacetanilide (HOLMBERG and PSILANDERHJELM), A., i, 534.
 α -, γ -, and δ -Ethylthiocodide, and their derivatives (PSCHORR and ROLLETT), A., i, 420.
 β Ethylthiocodide hydrochloride (PSCHORR and KRECH), A., i, 422.
 Ethylthioglycolphenylhydrazide (FRIEDRICH and FÜRSTER), A., i, 192.
 Ethylthioacetic acid, platinum salt, photo-transformation of (RAMBERG), A., i, 218.
 4-Ethylthiolanthraquinone, 1-acetyl-amino-1-amino-, and 1-benzoylamino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 751.
 1-Ethylthiolanthraquinone-5-sulphonic acid, sodium salt (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 751.
 2-Ethylthiol-6-pyrimidone, 5-cyano- (JOHNSON), A., i, 69.
 α -, β -, γ -, and δ -Ethylthiomethylmorphine, and their derivatives (PSCHORR and ROLLETT), A., i, 420.
 β -Ethylthiomorphide, and its diacetyl derivative and methiodide of the latter (PSCHORR and HOPPE), A., i, 423.
 Ethylthiovinyltetrahydromorphenol methyl ether (PSCHORR and ROLLETT), A., i, 420.
 Ethylthiazomalonic acid, and its ethyl ester and amide (FÜRSTER and MÜLLER), T., 133; P., 4.
 Ethyluric acid glycol (BLITZ and KRECH), A., i, 526.
 β -Ethylvaleric acid, menthyl ester of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 707.
 and α -bromo-, ethyl ester (FICHTER, KIEFER, and BERNOULLI), A., i, 89.
 β -Ethylvaleryl chloride, amide, and carbamide (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 707.
 Eudiometer, new form of (HAUSER), A., ii, 340.
 simplified, for gas analysis (RICHARDSON and JAFFE), A., ii, 341.
 (iii) Eugenol methyl ether bromohydrin (MANNICH and JACOBSON), A., i, 167.
 Eugenyl bromoethyl ether (WOHL and BERTHOLD), A., i, 620.
 Eugenyl vinyl ether (WOHL and BERTHOLD), A., i, 620.
 Eutectics, application of the laws of, to definite chemical compounds (VASTLIEFF), A., ii, 606.
 to silicate fusions (FLAWITSKY; HAUKE), A., ii, 510.
 Euxenite, analysis of (HAUSER and WIRTH), A., ii, 47.
 Euxenite earths, so-called (HAUSER and WIRTH), A., ii, 713.

Evaporation, laws of (VAILLANT), A., ii, 186.
 a special case of (VAILLANT), A., ii, 390.
 Explosion indicator (TRICU), A., ii, 892.
 Explosives, safety, containing ammonium nitrate, action of, in the presence of carbon, paper, and paraffin (DAURICHES), A., ii, 34.
 Extraction of heavy liquids with light solvents (EMDE), A., ii, 286.
 Extraction apparatus (ROBERTS), A., ii, 494; (BERL), A., ii, 538; (GREENE), A., ii, 747; (WALPOLE), A., ii, 907; (NOBLE), A., ii, 1053.
 improved (SANDERS), P., 227.
 for fat (CLAUSER), A., ii, 908.
 Dunstan and Short's, modification of (PERREDES), A., ii, 196.

F.

Fæces, phosphorus in (LIPSCHÜTZ), A., ii, 227.
 estimation of fat and fatty acids in (FOLIN and WESTWORTK), A., ii, 757.
 estimation of ferments in (URY), A., ii, 145.
 estimation of mercury in (SIEBERT), A., ii, 656.
 estimation of "saccharin" in (WAKEMAN), A., ii, 1011.
 Faradiol, and its acetate, propionate and phenylurethane (KLOBB), A., i, 31.
 Fasting (HOWE and HAWK; HOWE, MATTILL, and HAWK), A., ii, 728.
 Fat content in the human organs (MAGNUS-LEVY), A., ii, 426.
 synthesis, influence of bile on, due to lipase (HAMSK), A., ii, 427.
 and oils, hydrolysis of (WEGSCHEIDER), A., i, 6.
 the so-called, of tissues and organs (MACLEAN and WILLIAMS), A., ii, 142.
 absorption (LAMB), A., ii, 520.
 behaviour of, during autolysis and on preservation under aseptic conditions (ONTA), A., ii, 1087.
 cleavage by pancreatic juice (SERROINK), A., ii, 141.
 digestion of (USUKI), A., ii, 972.
 is assimilation of, in the body dependent on the composition of fat in the food? (ABDERHALDEN and BRAHM), A., ii, 520.
 alimentary, partial transformation of into mannitol by peptic and pancreatic digestion (GAUTRELET), A., ii, 140.

- Fat**, formation of sugar from, in phloridzin diabetes (LOMMEL), A., ii, 793.
 detection of benzoic acid in (FISCHER and GRUENERT), A., ii, 1121.
 estimation of (DIESELHORST), A., ii, 1003.
 estimation of, in faeces (FOLIN and WERTWORTH), A., ii, 757.
- Fats**, action of, on osmium peroxide (GOLODERZ), A., ii, 464.
 action of acids in the hydrolysis of, by castor oil seeds (TAKAKA), A., i, 800.
 substitution of the iodine numbers of, by the bromine numbers (VAUREL), A., ii, 1122.
 and oils, estimation of the acid and saponification numbers in (MARX), A., ii, 360; (MAYER), A., ii, 361.
 animal, viscosity measurements on (RAFFO and FORESTI), A., ii, 360.
 apparatus for the distillation of, in the vacuum of the cathode light (BROWN and THOMAS), P., 149.
 analysis of (DAVID), A., ii, 1123.
 estimation of, by the Kunagawa-Suto method (SHIMIDZU), A., ii, 1123.
 estimation of, in cocoa and chocolate (PROCHNOW), A., ii, 556.
 estimation of the total soluble fatty acids in (BRUNO), A., ii, 757.
- Fat extraction apparatus** (VAN KAALE), A., ii, 360.
- Felspar**, secondary, in sedimentary rocks (GRANDJEAN), A., ii, 419.
- Felspars**, French, analysis of (BARBIER and GONNARD), A., ii, 419.
- apoFenchene** hydrochloride and hydrobromide (BOUYEAULT and LEVALLOIS), A., i, 628.
- Fenchone**, preparation of, free from camphor (LEROIDE), A., i, 185.
 constitution of (BOUYEAULT and LEVALLOIS), A., i, 572, 627, 636, 863.
 hydrate and its dibenzoate and dicarbanilate (CIAMPICIAN and SILBER), A., i, 496.
- Fenchyl alcohol**, isomeric of, and its phenylurethane and phthalic acid ester (SCHIMMEL & Co.), A., i, 329.
- apoFenchylamine** (BOUYEAULT and LEVALLOIS), A., i, 573.
- Fermentation**, studies in (SLATOR and SAND), T., 922; P., 85.
 measurement of gases evolved during (HARDEN, THOMPSON, and YOUNG), A., ii, 937.
 alcoholic, new theory of (KUSSEROW), A., ii, 231.
 in the presence of sulphurous acid (POZZI-ESCOT), A., ii, 148.
- Fermentation**, alcoholic, production of glycerol during (ROMBERG and CARRACIDO), A., i, 350.
 formation of phosphates in (HARDEN and YOUNG), A., i, 292; ii, 643.
 chemical reactions occurring during (BUCHNER and MEISENHIMER), A., ii, 737.
 action of nitrates in (FERREACH and LANZENBERG), A., ii, 1067; (KAYSER), A., ii, 1098.*
 paralyzing action of acids on (ROSENBLATT and ROSENBLATT), A., ii, 643.
 by-products of (ASHDOWN and HEWITT), T., 1636; P., 160.
 trypsin, the law of (PALLADIN), A., ii, 912.
 yeast, the rôle of diffusion in (SLATOR and SAND), T., 922; P., 85; (BROWN), P., 130.
- Ferments**. See Enzymes.
- Ferratin**, influence of, on the iron content of the liver (IMABUCHI), A., ii, 324.
- Ferriacetates**. See under Iron.
- Ferricyanides**. See under Iron.
- "Ferripyrrole"**, estimation of (ASTREUC and BOUISSON), A., ii, 557.
- Ferroboron**, Goldschmidt's, behaviour of, on heating in chlorine and hydrogen sulphide (HOFFMANN), A., ii, 503, 509.
- Ferrocyanides**. See under Iron organic compounds.
- Ferro-silicon**, estimation of silicon in (PERSS), A., ii, 346; (NEURMAN), A., ii, 547.
- Ferrous salts**. See under Iron.
- Fibrin**, gastric and peptic digestion of (CROAT), A., ii, 728.
 putrefaction of, by bacteria (MCCREDEN), A., ii, 988.
- Fibrin-ferment** (GENARD), A., i, 509.
 estimation of, in body-fluids and organs (WOHLGEMUTH), A., ii, 361.
- Fibrinoheteroprotease** (LEVENE, VAN SLYKE, and BIRCHARD), A., i, 794.
- Fibrinogen**, estimation of, in body-fluids and organs (WOHLGEMUTH), A., ii, 364.
- Ficus carica**, chemical composition of (PALAHINO), A., ii, 441.
- Fig**. See *Ficus carica*.
- Filtering apparatus** (EISENSTEIN and ZIFFER), A., ii, 153; (BRENN), A., ii, 494.
- Fire-clay** of Glenboig, Lanarkshire (GREGORY), A., ii, 722; (McDONALD), A., ii, 723.
- Firefly**, production of light by the (KATLER and McDERMOTT), A., ii, 1038.
- Fish**, nutritive value of, in comparison with beef (SLOWIZOFF), A., ii, 326.

- Fish**, muscle, extractives of (KUTSCHER), A., ii, 55.
 selachian, gastric juice of (WEINLAND, GROHMANN, and STEFFEN), A., ii, 1082.
- Flame**, Bunsen. See Bunsen flame.
 the union of hydrogen and oxygen in (DIXON), T., 661.
- Flames**, cooling of (TECLU), A., ii, 705.
 extinction of (JORISSEN and SIWERSZ), A., ii, 122.
 detection of ozone in (MANCHOT), A., ii, 344.
- Flavanthren**, new method of preparation of (SCHOLL, MANSFELD, and POTTSCHWAUSCHEG), A., i, 494.
 reduction of (POTTSCHWAUSCHEG), A., i, 517.
tetra-aminodihydroxy-, dinitrodinitrosodihydroxy- (HOLDERMANN and SCHOLL), A., i, 285.
- Flavellagic acid** tetramethyl ether, and its acetyl derivative (HERZIG and SCHMIDINGER), A., i, 677.
- Flavone**, 2:3-dihydroxy-, and its diacetyl derivative and dimethyl ether (REICRODSKI and TAMBOR), A., i, 578.
- Flour**, bleached, digestibility of (ROCKWOOD), A., ii, 975.
- Fluidity and viscosity** (BINGHAM), A., ii, 395.
- Fluorene series** (SCHMIDT), A., i, 839.
 1-amino-9-hydroxy-, 1:9-diamino-, α -9-hydroxy- and 1:9-dihydroxy- and their derivatives (SCHMIDT and STÜTZEL), A., i, 31.
 9:9-dichloro- (SCHMIDT and WAGNER), A., i, 550.
 9-imino-, and its salts (KIEGEL), A., i, 733.
- Fluorene-9-aldehyde** and its derivatives (WISLICENUS and RUSS), A., i, 839.
- Fluorene-9-carboxylonitrile** (WISLICENUS and RUSS), A., i, 840.
- Fluorene-9-glycollic acid** (WISLICENUS and RUSS), A., i, 841.
- Fluorenone**, salts of, and compound with α -naphthol (MEYER), A., i, 180.
 hydrobromide periodide (GOMBERG and CONE), A., i, 872.
 6:8-dibromo (MONTAGNE), A., i, 42.
 1:8-dinitro-, and its phenylhydrazone, semicarbazone and oxime and its derivatives (SCHMIDT and STÜTZEL), A., i, 30.
- Fluorenoneanil** (REDDLIEN), A., i, 747.
- Fluorenone-p-nitrophenylhydrazone** (SCHMIDT and WAGNER), A., i, 550.
- Fluorenone-p-toluidine** (REDDLIEN), A., i, 747.
- Fluorenyl ether** (SCHMIDT and STÜTZEL), A., i, 30.
- Fluorenyl ethers** (KIEGEL), A., i, 733.
- Fluorescein di-perchlorate** (HOFFMANN and KIRMUTHNER), A., i, 105.
- Fluorescence**, ultra-violet, and chemical constitution of cyclic compounds (LEY and GRAFE), A., ii, 563; (LEY and v. ENGELHARDT), A., ii, 813.
- Fluorescent solutions**, electrolytic conductivity of (RASSENFOSSÉ), A., ii, 89.
- Fluorine**, distribution of, in the human organs (ZDARSK), A., ii, 1085.
 apparatus for the preparation of, and attempt to prepare oxygen compounds of (GALLO), A., ii, 405, 705.
 aromatic derivatives (MEYER and HUB), A., i, 735.
- Hydrofluoric acid** (*hydrogen fluoride*), electric conductivity and density of solutions of (HILL and SIKKAR), A., ii, 27.
 detection of, in the presence of fluorides (CRONHEIM), A., ii, 154.
- Fluorine**, detection of, in wines (KICKTON and BRENNKE), A., ii, 889.
 estimation of, in fluorite (LOZKA), A., ii, 542.
 estimation of, in aromatic fluorine derivatives (MEYER and HUB), A., ii, 996.
- Fluorone**, 3-hydroxy-, and its chloride (KEHRMANN and JONES), A., i, 409.
- Fluorones** (POPE and HOWARD), T., 1923; P., 113.
- Fongose**, relation of callose to (TANRET), A., i, 651.
- Foods**, new compound in (BACKÉ), A., i, 225.
 Bengali, composition of (SHERMAN and HIGGINS), A., ii, 444.
 detection of manganese in (DIMITRESCOU and NICOLAI), A., ii, 1001.
 estimation of benzoic acid in (VAN DER LAAN and TYDENS), A., ii, 759.
 estimation of nitrogen in (ENGELS), A., ii, 448.
 estimation of "saccharin" in (TESTONI), A., ii, 167; (TORTELLI and PIAZZA), A., ii, 908.
- Formaldehyde**, production of, in the oxidation of ethyl alcohol (VOISENET), A., i, 91.
 photochemical formation of, in green plants (SCHRYVEN), A., ii, 334.
 action of, on green plants (GRAFE and v. PORTHEIM), A., ii, 335.
 decomposition of, at a red heat (GAUTIER), A., i, 542.
 detection of, in wines (HUBERT), A., ii, 465; (SURRE), A., ii, 808.
 detection of traces of, in presence of acetaldehyde (DENIGES), A., ii, 357.

- Formaldehyde**, modification of Rimini's test for (SCHRYVER), A., ii, 334.
 estimation of (BRÄUTIGAM), A., ii, 1008.
 estimation of, in formalin soaps (ALLEMANN), A., ii, 465.
 titrations, use of sodium and barium hydroxides in (SØRENSEN), A., ii, 556.
- Formaldehydephenylhydrazones**, nitrocyano- (STEINKOPF, BOHEMANN, GRÜNNP, KIRCHHOFF, JURGENS, and BENEDEK), A., i, 307.
- Formaldehydesulphoxylic acid**, sodium salt. See Rongalite.
 zinc salt (BECKER), A., i, 298.
- Formamide** as a solvent for inorganic salts (RÖHLER), A., ii, 684.
- Formazyl- α -methylacrylic acid** (HENRICH, REICHENBURG, NACHTIGALL, THOMAS, and BAUM), A., i, 902.
- Formic acid**, occurrence of, in raspberries (RÖHRIG), A., ii, 235.
 formation of, by hydrolysis of lignin (CROSS), A., i, 457.
 synthesis of (BERTHELOT and GAUDICHON), A., ii, 564.
 mechanism of the action of bromine on (BOGNAR), A., ii, 282.
 fermentation of, with *Bacillus polymyxa* (FRANZEN and GREVE), A., ii, 799.
 fermentation of, by *Bacillus prodigiosus* (FRANZEN and GREVE), A., ii, 333.
 lead salt, crystalline form and optical characters of (KARANDÉEFF), A., i, 151.
 sodium salt, compound of, with acetic anhydride (TSAKALOTOS), A., i, 458.
 estimation of (JOSEPH), A., ii, 1118.
 estimation of, in the presence of acetic acid (DREHAYE), A., ii, 1007.
- Formiminomethyl ether methyl hydrogen sulphate** (MATSUI), A., i, 696.
- Formylbenz-*p*-nitroanilide** (MIMM and HESSE), A., i, 311.
- Formylcodeine** (FARBENFABRIKEN FORM. F. BAYER & Co.), A., i, 765.
- 9-Formylfluorene**. See Fluorene-9-aldehyde.
- Formylmorphine**, and its salts (FARBENFABRIKEN FORM. F. BAYER & Co.), A., i, 765.
- Fossil wood**, analysis of a (HAFT), A., ii, 1077.
- Fowls**, behaviour of benzoic acid and glycine in (YOSHIKAWA), A., ii, 880.
 behaviour of phenylacetic acid in (TOTANI), A., ii, 880.
- Fractionating apparatus** (HAHN), A., ii, 583.
- Fractionating column**, a new (HAHN), A., ii, 183.
- Frangula-emodin**, salts and derivatives, of (OESTERLE and JOHANN), A., i, 861.
- Freezing mixtures** (DUGLAUX), A., ii, 1034.
- Freezing-point**, raising or lowering of the (SCHREINEMAKERS), A., ii, 359.
 depression of, in very dilute solutions (BEDFORD), A., ii, 388.
 curve for mixtures of camphor and phenol (WOOD and SCOTT), T., 1573; P., 194.
 measurements on small quantities of liquids (BURIAN and DRUCKER), A., ii, 484.
- Freezing-points of gaseous mixtures** (BAUME and PERROT), A., ii, 825.
- Friedel-Crafts' reaction** applied to naphthalene (HOMER), T., 1141; P., 11.
 with chlorides of unsaturated acids (KÖHLER, HERITAGE, and BURNLEY), A., i, 562.
 with unsymmetrical polycarboxylic acids (KIRPAL), A., i, 594.
- Frogs**, blood coagulation in (PRINGLE and TAIT), A., ii, 725.
 heart of. See under Heart.
 muscle. See Muscle.
 nerves. See Nerves.
 ovary. See Ovary.
 skin, effect of deprivation of oxygen on the resting current of (MANFIELD), A., ii, 222.
- α -Fructose**, acetone derivatives of (IRVINE and GARRETT), T., 127; P., 143.
- α - and β -Fructosemonooacetone** (IRVINE and GARRETT), T., 1283; P., 143.
- Fruit**, chemical organisation of a typical (VINSON), A., ii, 740.
 of *Menispermum Canadense* (NEIDUD), A., ii, 801.
- Fruits which ripen after being gathered**, composition of (OTTO and KOORER), A., ii, 233, 439.
 occurrence of arsenic in (HEADEN), A., ii, 520.
- Fuchsine** from Birm, Switzerland (PRIOR), A., ii, 781.
- Fulminic acid** (WÖHLER), A., i, 231.
 condensation of azoimide with (PALAZZO), A., i, 342.
- Fumaric acid**, bromo-, lyridine salt of (PFEIFFER, LANGENBERG, and BUESCHWEIG), A., i, 578.
- Fungi**, decomposition of cyanamide by (KATZEN), A., ii, 436.
 hydrolysis of racemic amino acids by (PRINGSHEIM), A., ii, 437.
 higher, chemistry of the (ZELLNER), A., ii, 886.

- Fungi mould, assimilation of ammonia and nitrates by (RITTER), A., ii, 230.
- edible, estimation of choline in (POLSTORFF), A., ii, 234.
- Furan, absorption spectrum of (PURVIS), T., 1648; P., 201.
- Furfuraldehyde, absorption spectrum of (PURVIS), T., 1648; P., 201.
- reaction of sesame oil with (VAN ECK), A., ii, 556.
- semicarbazone (KNÖPFER), A., i, 433.
- Furfurylideneacetone, phenylhydrazones of (AUWERS and VOSS), A., i, 71.
- Furfurylpropylcarbinol, and its chloride and acetate (JOLKEVER), A., i, 55.
- Furoylacetic acid, ethyl ester, salts and derivatives of (TORREY and ZANETTI), A., i, 892.
- Furoylmalonanilic acid, ethyl ester (TORREY and ZANETTI), A., i, 892.
- Furylacrylic acid, benzoylamino-, lactimide of (FLATOW), A., ii, 321.
- Furylalanine (FLATOW), A., ii, 322.
- 3-Furylscorazolone (TORREY and ZANETTI), A., i, 892.
- Furylpropionic acid, behaviour of, in the animal body (SASAKI), A., ii, 637.
- 3-Furyl-5-pyrazolone, and its picrate and acetyl derivatives (TORREY and ZANETTI), A., i, 892.
- 3-Furyl-5-pyrazolone-1-benzene-*p*-sulphonic acid (TORREY and ZANETTI), A., i, 893.
- Fusel oil, theory of the formation of (RODRIGUEZ CARRACIDO), A., i, 350.
- colour reaction of, with salicylaldehyde and sulphuric acid (KREIS), A., ii, 552.
- G.**
- Gageite from Franklin, New Jersey (PHILLIPS), A., ii, 963.
- Galactans, nutritive value of (SWARTZ), A., ii, 727.
- α - and β -D-Galactometasaccharin, salts of (NEF and LUCAS), A., i, 714.
- Galactose, fermentation of, by yeast (HARDEN and NORRIS), A., ii, 989.
- detection of, in lipoids (FRÄNKEL and LINNERT), A., i, 600.
- Galactosides, preparation of (ROSENHEIM and TRUB), A., ii, 1085.
- Gallacetophenone, α -amino-, hydrochloride (BARGE and EWINS), T., 2261; P., 248.
- Gallein perchlorate (HOFMANN, MERZLER, and HÖBOLD), A., i, 370.
- Gallic acid, action of arsenic acid on (LUIX), A., i, 908.
- Gallipharic acid, metallic salts of (KUNZ-KRAUSE and MANICKE), A., i, 458.
- cyclo*Gallipharic acid, degradation of, by oxidising agents (KUNZ-KRAUSE and MANICKE), A., i, 677.
- cyclomeso*Gallipharic acid (KUNZ-KRAUSE and MANICKE), A., i, 677.
- Gallipinic acid (KUNZ-KRAUSE and MANICKE), A., i, 678.
- Galloflavin (HERZIG, ERDÖS, and RIZICKA), A., i, 676.
- iso*Galloflavin, tri- and tetramethyl ethers (HERZIG, ERDÖS, and RIZICKA), A., i, 676.
- Gallotannic acid, ethyl ester (MANXING), A., i, 851.
- Gammarus*, blood coagulation in (TAIT), A., ii, 725.
- Garnet containing iron and chromium (COLOMBA), A., ii, 968.
- Gas, action of sodium benzoate on the production of, by bacteria (HERTER), A., ii, 147.
- illuminating, preparation of, as a lecture experiment (TECU), A., ii, 602.
- analysis of (ELLIOTT), A., ii, 353.
- Gases, volcanic (BRUN), A., ii, 135.
- specific heats and equilibria of, from explosion experiments (PIER), A., ii, 1031.
- ionisation in (METCALFE; DE BROGLIE and BRIZARD), A., ii, 11; (DE BROGLIE), A., ii, 480.
- refraction of, and its application to analysis (STUCKMUTH), A., ii, 245.
- theory of dispersion in (NATANSON), A., ii, 170.
- pressure of light on (LEBEDEFF), A., ii, 472.
- influence of pressure on the absorption of ultra-red radiation by (v. BAHR), A., ii, 914.
- adsorption of, by charcoal (HOMFRAY), A., ii, 771, 1041; (TITOFF), A., ii, 1041.
- determination of viscosity of (RANKINE), A., ii, 188.
- solubility of, in metals and alloys (SIEVERTS and KRUMHABER), A., ii, 410.
- in water, influence of colloids and fine suspensions on the (FINDLAY and CREIGHTON), T., 536; P., 44.
- solubility of, in sulphuric acid and in mixtures of sulphuric acid and water (BOHR), A., ii, 198.
- reaction of, on alkali metals, production of negative electrons during the (HABER and JUST), A., ii, 572.
- chemically inert, occurrence of free electrons in (FRANCK), A., ii, 817.
- at low pressures, friction in (HOGG), A., ii, 271.

- Gases**, rate of evolution of, from homogeneous liquids (VELEY and CAIN), A., ii, 25.
- submitted to very high pressures, chemical reactions in (BRINER and WROCZYŃSKI), A., ii, 120, 707.
- chemical effects of ultra-violet light on (BERTHELOT and GAUDECHON), A., i, 349; ii, 564, 606.
- of the argon group, viscosities of (RANKINE), A., ii, 409, 829.
- liquefied, binary mixtures of (STEELE and HAGSTER), T., 2607; P., 253.
- rarefied, conduction of heat through (SODDY and BERRY), A., ii, 180.
- theory of transpiration, diffusion, and thermal conduction (SMOLUCHOWSKI), A., ii, 1042.
- action of, on green plants (MIRANDE), A., ii, 884.
- improved method of collecting, from the mercury pump (KEYES), A., ii, 66.
- apparatus for measuring the volume of (MÜLLER), A., ii, 893.
- apparatus for demonstrating the volumetric composition of (FENEY), T., 1200; P., 131.
- containing helium from the German salt beds (ERDMANN), A., ii, 376.
- from mineral springs, analysis of (HINTZ and GRUNERT), A., ii, 356, 1111; (HENRICH), A., ii, 1111.
- of sulphur furnaces, estimation of sulphuric acid and sulphur dioxide in (PELLET), A., ii, 69.
- Gas-absorption apparatus** (BILLY), A., ii, 704.
- Gas-absorption pipette**, modification of Nowicki's (DE KONINCK), A., ii, 648.
- Gas analysis** by condensation (ERDMANN and STOLTZENBERG; STOLTZENBERG), A., ii, 649.
- use of phosphorus solutions in (CENTNEISZWEIG), A., ii, 541.
- by means of refractive power (STUCKERT), A., ii, 245.
- apparatus (ELLIOTT), A., ii, 353; (CHLIG), A., ii, 354.
- apparatus, automatic (HOMANN), A., ii, 237.
- simplified endiometer for (RICHARDSON and JAFFÉ), A., ii, 341.
- with the "decomposition flask" (BERL and JURISSEN), A., ii, 240, 242.
- improvement in Fresenius' method for estimating hydrocarbons (HENRICH), A., ii, 355.
- Gas-burette**. See under Burette.
- Gas exchange**, mechanism of (KROGH and KROGH; KROGH), A., ii, 512.
- Gas generator** in connexion with the nitrometer (RUPP), A., ii, 344.
- Gas volumes**, graphic method for correction of (FARMER), A., ii, 686.
- Gas-washing apparatus** (CLEMMING), A., ii, 841.
- Gaseous explosions** (BRITISH ASSOCIATION REPORTS), A., ii, 687.
- Gaseous mixtures**, explosibility of (ERSTEIN and KRASSA), A., ii, 202.
- Gastric digestion**. See Digestion.
- Gastric fluid**, quantity of secretion in the (WINTER), A., ii, 786.
- Gastric juice**, action of thermal influences on the digestive power of (ROEDER), A., ii, 423.
- occasional occurrence of urebilin in (LAVIALLE), A., ii, 729.
- of man and dog, the proportionality of proteolytic and rennetic action of, in normal and pathological cases (MIGAY and SAWITSCH), A., ii, 140.
- of ox and calf, chymosin and pepsin in the (RÁKOCZY), A., i, 801.
- of the selachian fishes, hydrochloric acid of the (WEINLAND, GROMANN, and STEFFEN), A., ii, 1082.
- analysis of (TAMAYO), A., ii, 667.
- Gastrotoxin** and the healing of gastrotoxic ulcers (BOLTUN), A., ii, 731.
- Gelatin** (TRUNKEL), A., i, 704.
- optical rotation of (TRUNKEL), A., i, 648.
- crystallisation of (V. WEIMANN), A., ii, 1046.
- destruction of, by *Micrococcus prodigiosus* (MESERNITZKY), A., ii, 1067.
- deminerallised, preparation and properties of (DIERÉ and GORGOLEWSKI), A., i, 448.
- a colour reaction for (LIESEBANG), A., ii, 84.
- Gelatinisation**, mechanism of (V. WEIMANN), A., ii, 1046.
- Gelsmium*, the constituents of Moore, T., 2223, P., 247.
- Gentian root**, preparation of gentiopieirin from (BOUQUELIOT and BRIDEL), A., ii, 337.
- Gentiana pneumonanthe*, occurrence of gentiopieirin in roots and stems of (BOUQUELIOT and BRIDEL), A., ii, 887.
- Gentiopieirin**, presence of, in *Chelon perfoliata* (BOUQUELIOT and BRIDEL), A., ii, 234.
- occurrence of, in roots and stems of *Gentiana pneumonanthe* (BOUQUELIOT and BRIDEL), A., ii, 887.
- preparation of (BOUQUELIOT and BRIDEL), A., ii, 337.

- aceto*Geranic acid, action of hypotonic acid on (ROUGAULT), A., i, 254.
 derivatives of (BOUVEAULT), A., i, 380.
 Geraniol, action of hydrochloric acid on (DUPONT and LABAUNE), A., i, 184.
 odour, cause of (AUSTERWEIL and COCHIN), A., i, 687.
 oxides of (PRIELESCHAEFF), A., i, 86.
*aceto*Geraniol, phenylurethane of (BOUVEAULT), A., i, 380.
*cyclo*Geraniolene, synthesis of (CROSSLEY and GILLING), T., 2218; P., 252.
 Geranium oil (SCHIMMEL & Co.), A., i, 757.
*aceto*Geranyl acetate (BOUVEAULT), A., i, 380.
 Germanium, extraction of, from blends (URBAIN, BLONDEL, and OBERDOFF), A., ii, 717.
 Germination, action of aqueous solutions of electrolytes on (MICHEELS), A., ii, 232.
 action of anodic and cathodic liquids on (MICHEELS), A., ii, 883.
 Gland, thyroid. See under Thyroid.
 Glands, physiology of (ASHER and KARATLOW), A., ii, 628.
 mammary, enzymes of (GRIMMER), A., ii, 825.
 milk, scission products of the nucleoprotein of (MANDEL), A., i, 147.
 salivary. See under Salivary.
 Glass, electrolysis of (LE BLANC and KESCHBAUM), A., ii, 481; (HEYDWEILLER and KOPFERMANN), A., ii, 685.
 permeability of, for vapours (ZENGEIS), A., ii, 504.
 supposed permeability of (ELSDEN), P., 7.
 action of the α -rays on (RUTHERFORD), A., ii, 175.
 eosin reaction of, at fractured surfaces (MYLIUS), A., ii, 656.
 Glauconite, submarine, chemistry of (CASPARI), A., ii, 722.
 Glaucophyllin, and its potassium salt (WILLSTÄTTER and FRITZSCHE), A., i, 128.
 Glucoporphyrin, and its salts (WILLSTÄTTER and FRITZSCHE), A., i, 129.
 Gliadin, action of the gastric juice on (BAGLIONI), A., ii, 625.
 Globulins, precipitation of, at the isoelectric point (RONA and MICHAELIS), A., i, 805.
 Glow light at points, spectral analysis of (DECHEND), A., ii, 2.
 β -Glucosases, distribution of, in plants (ARMSTRONG, ARMSTRONG, and HORTON), P., 334.
 Glucinum, action of, on the frog's heart (MINES), A., ii, 525.
 Glucinum lactate (CALCAGNI), A., i, 705.
 sulphate, hexahydrated (LEVI-MALVANO), A., ii, 37.
 formates (TANATAR), A., i, 354.
 Glucosamine hydrochloride, preparation of, from ovomucoid (OSWALD), A., i, 716.
 Glucoseanilide-*o*-carboxylic acid (MERCK and FLIMM), A., i, 438.
 Glucoside of *Erennostachys laciniata* (KHOURI), A., ii, 151, 886.
 cyanogenetic, occurrence of, in *Linaria striata* (BOURQUELOT), A., ii, 63.
 in the leaves of the pear tree (BOURQUELOT and FICHTENHOLZ), A., ii, 742.
 of *Pyrola rotundifolia* (FICHTENHOLZ), A., ii, 889.
 from *Tephrosia purpurea* (CLARKE and BANERJEE), T., 1833; P., 213.
 Glucosides, formation of, by plants (CIAMICIAN and RAVENNA), A., ii, 234.
 in species of *Veronica* (VINTILESCO), A., ii, 339.
 Glucosides. See also:—

*iso*Trifolin.
 Glucosyringic acid, synthesis of (MATTHESE), A., i, 677.
 Glus, delicate reaction for (SCHMIDT), A., ii, 911.
 Glutaconic acid group, stereochemistry of (FRIST), A., i, 7.
 Glutaconic acid, ethyl ester, mesityl-*o*-phenetyl-, phenyl-, *p*-nitrophenyl- and *az-m*-xylylhydrazones (HENRICH, REICHENBURG, NACHTIGALL, THOMAS and BAUM), A., i, 901, 902.

- Glutamic acid**, preparation of salts of (ABDERHALDEN and KAUTZSCH), A., i, 230.
 copper salt of (MORGENSTERN and ZERNER), A., i, 656.
 ethyl ester, action of diazo-compounds on (HENRICH, REICHENBURG, NACHTIGALL, THOMAS and BAUM), A., i, 900.
 metallic salts of (ABDERHALDEN and KAUTZSCH), A., i, 769.
 separation and estimation of aspartic acid and (OSBORNE and LIDDLE), A., ii, 1007.
- Glutardialdehyde**, derivatives of (HARRIS), A., i, 361.
- Glutaric acid**, β -imino- α -cyano-, ethyl ester, and its alkyl derivatives, constitution of (CAMPELL and THORPE), T., 1229; P., 176.
- Glycemia** at a very high altitude (BAYEUX), A., ii, 875.
- Glyceric acid**, di- α -naphthylurethane of (NEUBERG and HIRSCHBERG), A., i, 694.
- Glycerides** of butter fat (SIEGFELD), A., ii, 327.
 mono-, syntheses of (GRÜN), A., i, 356.
- Glycerol**, production of, during alcoholic fermentation (CARRACIDO), A., i, 350.
 association of (ELIÉEFF and KURBATOFF), A., ii, 103.
 mixtures of, with alcohols, free energy of chemical action in (PISSAREWSKY and TRACHONOTOWSKY), A., ii, 402.
 electrolysis of (LÖR and PULERMACHER), A., i, 94.
 complex compounds of, with the alkaline earth metals (GRÜN and HUMANN), A., i, 352.
 mono- and di-bromohydrins, preparation of (CARRÉ), A., i, 649.
 α -monochlorohydrin, preparation of aryl ethers of (BOYD and MARLE), T., 1788; P., 208.
 mono- and di-lactates (KALLE & Co.), A., i, 297.
o- and *p*-chlorophenyl ethers (LES ÉTABLISSEMENTS POULENC FRÈRES and FOURNEAU), A., i, 373.
 phenyl ethyl, di-*p*-tolyl, di- α -naphthyl and di-*p*-nitrophenyl ethers (FOURNEAU), A., i, 246.
o-, *m*-, and *p*-tolyl and α - and β -naphthyl ethers (ZIVKOVIĆ), A., i, 246.
- Glycerol**, estimation of, in wines (BÉYS), A., ii, 758.
- Glycerolmonotyrosine** (ABDERHALDEN and GUGGENHEIM), A., i, 226.
- Glyceryl triformate** (ROMBURGH), A., i, 215.
 trinitrate (*nitroglycerin*), alkaline hydrolysis of (BERL and DELFY), A., i, 456.
 bromoisovalerate dipalmitate (ABDERHALDEN and GUGGENHEIM), A., i, 226.
- Glycide ethers** from guaiacol and thymol (FOURNEAU), A., i, 246.
 aryl ethers, action of ammonia on (BOYD), T., 1791; P., 209.
- Glycidic acid**, esters of, action of halogen acids on (DARZENS), A., i, 460.
- Glycinamide**, preparation of (SCHENCK), A., i, 100.
- Glycine**, ethyl ester, hydrobromide of (FISCHER and SCHRAEDER), A., i, 270.
Glycine hispida (*soy bean*), putrefaction bases from the decomposition of (YOSHIMURA), A., ii, 1103.
- Glycocholic acid**, sodium salt, influence of, on tryptic digestion (QUAGLIARIELLO), A., ii, 627.
- Glycocyanamine** (SCHENCK), A., i, 546.
- Glycocyanidine** (SCHENCK), A., i, 546.
- Glycogen**, the parent substance of (PFLÜGER and JENKENS DORF), A., ii, 225.
 formation of, in the liver of tortoises with pancreatic diabetes (NISHI), A., ii, 227.
 in the frog's ovary (KATO; BLEIBTERT), A., ii, 628.
 oxidation and hydrolysis of, by hydrogen peroxide (GATIN GRUZEWSKA), A., i, 610.
 estimation of (GRUZE; PFLÜGER), A., ii, 81.
 influence of iron on the estimation of (STARCKENSTEIN), A., ii, 792.
- Glycogenase**, distribution of, in the animal body (MACLEOD and PRABE), A., ii, 144.
- Glycol**, $C_{10}H_{20}O_8$, from action of magnesium tert.-butyl chloride on ethyl oxalate (EGOROVA), A., i, 91.
 $C_{11}H_{20}O_8$, from 2-methoxy-1-methyl-3- ψ -allylbenzene (GUILLATMIN), A., i, 478.
- Glycol**. See Ethylene glycol.
- Glycols**, complex compounds of, with metallic salts (GRÜN and BODPEREN), A., i, 351.
 diprimary, synthesis of (DIONNEAU), A., i, 353.
 Δ -acetylenic, oxidation of (DITON), A., i, 456.
 optically active, from *l*-benzoin and from methyl *l*-mandelate (MCKENZIE and WREN), T., 473; P., 54.

- α*-Glycols**, action of dehydrating agents on (TIEFFENAU), A., i, 379.
- β*-Glycolglicocide**, tetra-acetyl (FISCHER and FISCHER), A., i, 717.
- β*-Glycol *d*-glicoside** (FISCHER and FISCHER), A., i, 718.
- Glycolysis** (MICHAELIS and RONA), A., ii, 139.
- in the tissues (DE MEYER), A., ii, 631.
- at a very high altitude (BAVEUX), A., ii, 875.
- Glycosuria**. See Diabetes.
- Glycuronic acid**, new method of obtaining (NEUBERG and LACHMANN), A., i, 325.
- excretion of, after administration of aromatic compounds (STERN), A., ii, 850.
- new reaction for (GOLDSCHMIEDT), A., ii, 555.
- detection of, in urine (JOLLES), A., ii, 164; (GOLDSCHMIEDT), A., ii, 759; (BERNIER), A., ii, 1121.
- and ethereal sulphates in human urine (TOLLENS), A., ii, 732.
- estimation of, in urine (TOLLENS and STERN), A., ii, 328.
- Glycyl-*d*-alanyl-*l*-leucyl-*d*-isoleucine**, and its copper salt (ABDERHALDEN and HIRSCH), A., i, 720.
- Glycylallylamine**, and its picrate and benzoyl derivative (HARRIES and PETERSKN), A., i, 228.
- Glycyl-*l*-aspartic acid** (FISCHER and FIEDLER), A., i, 656.
- Glycylaspartylglycine** (FISCHER and FIEDLER), A., i, 857.
- Glycylcholesterol**, and its hydrochloride (ABDERHALDEN and KAUTZSCH), A., i, 253.
- Glycyl-*dl*-leucylamide**, and its hydrochloride (BERGELL and v. WÜLFING), A., i, 365.
- Glycyl-*l*-leucine** (ABDERHALDEN and WEBER), A., i, 719.
- Glycyl-*l*-isoleucine**, and its anhydride (ABDERHALDEN and SCHULER), A., i, 304.
- Glycyl-*l*-leucyl-glycyl-*l*-leucine** (ABDERHALDEN and WEBER), A., i, 719.
- Glycyl-*dl*-serine**, and its anhydride (FISCHER and ROESSEN), A., i, 657.
- Glyoxaline**, 1:2:4:5-tetraiodo- (PAULY), A., i, 639.
- Glyoxalines**, tautomerism of (PYMAN), T., 1814; P., 211.
- Glyoxylylpropionanilide**, and its salts (WINDAUS), A., i, 283.
- Glyoximeperoxides** (*dinitroscyls*), action of primary amines on (BOESEKEN), A., i, 643.
- Glyoxylic acid**, injury to the heart from (KAHN and STARCKENSTEIN), A., ii, 976.
- Gnaphalium avenarium***, oil from the flowers of (HAESESEL), A., i, 864.
- Gnoscopine** (*dl-narcotine*), synthesis of (PERKIN and ROBINSON), P., 46.
- resolution of (PERKIN and ROBINSON), P., 131.
- hydrochloride, picrate, and picronolate (RABE and McMILLAN), A., i, 335.
- Gnoscopine**, amino-, acetyl-amino-, and nitro-, and derivatives (HOPE and ROBINSON), P., 223.
- Gold**, solubility of, in nitric acid (DEWKY), A., ii, 304.
- solubility of, in potassium ferrocyanide (BEUTEL), A., i, 723.
- effect of ferric and cupric salt solutions on (McCAUGHEY), A., ii, 42.
- colloidal, preparation of (OECHSNER DE CONINCK), A., ii, 963.
- optics of (ROLLA), A., ii, 301.
- hydrosols (THOMAE), A., ii, 42.
- particles, ultra-microscopic, formation of, by the action of ultra-violet light on solutions of gold salts (SVEDBERG), A., ii, 509.
- salts, action of ultra violet light on solutions of gold salts (SVEDBERG), A., ii, 509.
- Gold alloys** with cobalt (WAHL), A., ii, 299.
- with magnesium (URAZOFF), A., ii, 43; (URAZOFF and VOGEL), A., ii, 872.
- Gold chloride**, auto-oxidation of (VANINO and ROSSLER), A., ii, 620.
- hydroxide, action of, on potassium ferrocyanide (BEUTEL), A., i, 723.
- Chloroauric acid**, action of, on potassium ferrocyanide in aqueous solution (BEUTEL), A., i, 722.
- Aurous cyanide**, action of, on potassium ferrocyanide (BEUTEL), A., i, 723.
- Gold**, qualitative test for small quantities of (ARMANI and BARBONI), A., ii, 659.
- estimation of, by means of hydrogen peroxide (ROSSLER), A., ii, 1115.
- Gold bullion assay**, accuracy of the (PHELPS), T., 1272; P., 139.
- Gorgonic acid**, iodo-. See Tyrosine, *di*-iodo-.
- Gout** (GUDZENT), A., ii, 146; (BECHHOLD and ZIEGLER), A., ii, 329.
- calcium metabolism in (MACKARELL, MOORE, and THOMAS), A., ii, 732.
- Grahamite** (RICHARDSON), A., ii, 964.

- Graphite**, estimation of iron in, by combustion (DENSTEDT and KLÖNDEK), A., ii, 547.
 estimation of combustible sulphur in (CIBULKA), A., ii, 749.
- Grass**, effect of manganese on (GUTHRIE and COHEN), A., ii, 444.
- Greenockite** (FROMME), A., ii, 314.
- Grignard reagents** (BÖDYKER), A., i, 214.
 action of, on camphoric and isocamphoric esters (SHIBATA), T., 1239; P., 141.
 action of, on methylethylacetaldehyde (BELOUSS), A., i, 706.
 action of, on methyl α -methoxysuccinate, methyl maleate, and maleic anhydride (FORDIE and ARUP), T., 1537; P., 199.
- Growth**, biochemistry of (CRAMER and PRINGLE), A., ii, 635.
- Guaiaacol**, action of phosphorus trichloride on (DUPUIS), A., i, 248.
 condensation of benzaldehyde with (MANCHOT), A., i, 314.
- Guaiacum resin**, catalytic oxidation of by copper (COLWELL), A., i, 54.
- Guaiaacylacetate**, 4-nitro- (WEGSCHEIDER and KLEMENC), A., i, 672.
- Guaiaoyl ω -bromoethyl ether** (WOHL and BERTHOLD), A., i, 620.
- Guaiaoylphosphorus chloride and tetrachloride** (DUPUIS), A., i, 248.
- Guaiaoyl vinyl ether** (WOHL and BERTHOLD), A., i, 620.
- Guanidine**, and derivatives of (SCHENCK), A., i, 99.
 amino-, diazo-compounds from (HOFMANN and ROTH), A., i, 232; (HOFMANN, HOCK, and ROTH), A., i, 446.
- γ -Guanidinobutyric acid**, synthesis of, and its auri- and hydrochlorides (ENGLAND and KÜTSCHER), A., i, 825.
- α -Guanidinohezoic acid**, ϵ -benzoylamino-, and ϵ -amino-, derivatives of its anhydride (FISCHER and ZEMPLÉN), A., i, 305.
- α -Guanidinohezoic anhydride**, ϵ -amino-, and its platinumchloride (FISCHER and ZEMPLÉN), A., i, 612.
- Guanine**, conversion of, into xanthine (FISCHER), A., i, 336.
- Guaninepropionic acid**, ethyl ester and its hydrochloride (FARBENFABRIKEN VORM. F. BAYER & CO.), A., i, 79.
- α -Guanino- ω -valeric acid**, δ -amino-, and δ -benzoylamino-, synthesis of (SÖRKESSEN), A., i, 227.
- Guanosine**, occurrence of, in the pancreas (LEVENE and JACOBS), A., ii, 978.
- Guaanylazoimide perchlorate** (HOFMANN, HOCK, and ROTH), A., i, 447.
- Guaanyloarbamide**, and its hydrogen, sulphate and picrate (SOLL and STUTZER), A., i, 14.
- Guaanyloarbamidesulphonic acid**, and its ammonium, barium, and calcium salts (SOLL and STUTZER), A., i, 14.
- Guaanyldiazoguaanyltetrazen** (HOFMANN, HOCK, and ROTH), A., i, 446.
- Guaanylic acid** (BANG), A., i, 647, 906.
 from the pancreas (STUTZER, and BRIGL), A., i, 703.
- Guaanyltetrazyltetrazen** (HOFMANN, HOCK, and ROTH), A., i, 446.
- Gnava-leaf oil** (SCHIMMEL & CO.), A., i, 329.
- Guinea-pig**, injection of peptone in the (BIEDL and KRAUS), A., ii, 736.
 purino enzymes of (MITCHELL), A., ii, 731.
- Gum-acacia**, enzymes of (CHAFÉ), A., i, 148; (REINITZER), A., i, 200.
- Gums**, from *Acacia pyramantha*, *Acacia horrida*, *Acacia arabica*, and *Melia Azadirachta* (MEININGER), A., i, 368.
- Gun-cotton**, action of alkalis on (PIEST), A., i, 464.
 detection of mercuric chloride in (JANNOPoulos), A., ii, 549.
- Gunpowder**, estimation of chlorates in (FAGES VIRGILI), A., ii, 348.
- α -, β -, and iso-Gurjunene** (DEUSSEN and PHILIPP), A., i, 575.
- Gurjun oil** (DEUSSEN and PHILIPP), A., i, 687.
- Gynocardase** (MOORE and TUTIN), T., 1285; P., 182.
- Gynocardin** and its sodium derivative (MOORE and TUTIN), T., 1285; P., 182.
- Gypsum**, apparatus for testing (VAXT HOFF), A., ii, 318.
- Gyrolite** from Co. Antrim (FLEISCHMANN), A., ii, 310.

H.

- Hæmochromogen** (KALINUS), A., ii, 664; (MITA; LOCHTE), A., ii, 665.
- Hæmocyanin** of *Limulus polyphemus* (ALSBERG and CLARK), A., i, 647.
- Hæmoglobin**, osmotic pressure of (ROSE), A., i, 209.
 crystals, preparation of (OFFENBACH), A., i, 793.
 combination of, with mixtures of oxygen and carbon monoxide (KROGH), A., ii, 512.
 behaviour of, towards hydrazine (LEFSCHIE), A., i, 599.
 of molluscs, comparison of, with that of vertebrates (PALADINO), A., ii, 50.

- Hemolysis** (GROS), A., ii, 51, 1082;
(SUTHERLAND and McCAY), A., ii, 223; (FISCHER), A., ii, 970.
by lipoids (MEYERSTEIN), A., i, 514;
(LIEFMANN and COHN), A., ii, 728.
by cobra poison (BANG), A., ii, 229.
in the liver (FINDLAY), A., ii, 783.
by soaps, inhibition of (MEYERSTEIN), A., ii, 223.
as a means of detecting saponin in beer, wine, and aerated waters (RUSCONI), A., ii, 559.
- Hemolytic agents**, action of, on pancreatic lipase (ROSENHEIM and SHAW-MACKENZIE), A., ii, 517.
- Hemopyrrole** (PILOTY and QUITMANN); A., i, 133; (LEYKO and MARCHELEWSKI), A., i, 144; (MARCHELEWSKI), A., i, 188.
- Halochromy**, theory of (PFEIFFER, HALPERIN, PROS, and SCHWARZKOFF), A., i, 852.
- Halogen**, replacement of, by the nitro-group (RAIFORD and HEYL), A., i, 373, 730.
reactivity of the, in organic compounds (SENTER), T., 346; P., 23, 344.
- Halogens**, conductivity of, in nitrobenzene (BRUNER and GALECKI), A., ii, 382.
action of, on mercuricamphor compounds (MARSH), T., 2410; P., 297.
conversion of, into alkali halogen salts (MESCHOREK), A., ii, 410.
velocities of certain reactions between metals and (VAN NAME and EDGAR), A., ii, 280.
Beilstein reaction for (MILROTH), A., ii, 67.
estimation of, in organic substances (MARCUSSEN and DÖSCHER), A., ii, 543.
- Halogen acids**, analysis of mixtures of (DEHN), A., ii, 67.
- Halogen compounds**, thermochemical investigations of (SVETOSLAVSKY), A., ii, 187.
the relation between reactivity and chemical constitution of (CLARKE), T., 416; P., 28.
organic, the action of calcium and lithium on (SPENCER and PRICE), T., 385; P., 26.
interaction of, with metals of the iron group (SPENCER and HARRISON), P., 118.
in the United States Pharmacopœia, estimation of the (ELYOVE), A., ii, 905.
- Halogen hydrides**, dielectric constants of (SCHAEFER and SCHLUNDT), A., ii, 12.
- Halogenalkyloxy-carboxylic acids**, aromatic, preparation of (CHEMISCHE FABRIK VON HEYDEN), A., i, 37.
- Harmaline**, pharmacological action of (GUNN), A., ii, 638.
- Heart**, influence of carbon dioxide on the beat of (JERUSALEM and STALLING), A., ii, 524.
injury to the, from glyoxylic acid (KAHN and STARKENSTEIN), A., ii, 976.
metabolism. See under Metabolism.
muscle, union of poisons with (VERNON), A., ii, 1086.
extractives and digitals (SCHLIOMENSUN), A., ii, 976.
dog's, gaseous metabolism of, during vagus inhibition (WOLFSOHN and KETRON), A., ii, 222.
frog's, action of barium chloride on the (POULSSON), A., ii, 529.
action of glaucinum, lanthanum, yttrium and cerium on the (MINES), A., ii, 525.
action of praseodymium, didymium and erbium on the (MINES), A., ii, 794.
mammalian, action of aconitine on (CUSHNY), A., ii, 224.
isolated mammalian, action of blood proteins on the (GORHAM and MORRISON), A., ii, 324.
tortoise, respiration of the, in relation to functional activity (VERNON), A., ii, 524.
- Heat**. See under Thermochemistry.
- Hedera-peroxydase** (VAN DER HAAR), A., i, 604.
- Hedysarum coronarium* (*Soota clover*), nitrogen-free extract of (SCURTI), A., ii, 744.
- Helianthus tuberosus*, presence of betaine in the tubers of (SCHULZE), A., ii, 534.
- Helium**, accumulation of, in geological time (STRUTT), A., ii, 9, 175, 920.
in recent minerals (PIUTTI), A., ii, 767.
in non-radioactive minerals (PIUTTI), A., ii, 677.
in the air of Naples and in Vesuvius (PIUTTI), A., ii, 290.
gases containing, from the German salt-beds (ERDMANN), A., ii, 376.
production of, by radium (RUTHERFORD and BOLTWOOD), A., ii, 175; (DEWAR), A., ii, 376.
liberation of, from minerals by the action of heat (WOOD), A., ii, 610.
rate of production of, from thorinite and pitchblende (STRUTT), A., ii, 1023.
density and molecular weight of (WATSON), T., 810; P., 70.

- Helium**, spectrum of (HICKS), A., ii, 86.
 measurement of normal lines in the
 (EVERSHED), A., ii, 369.
 ultra-red line spectrum of (PASCHEN),
 A., ii, 1014.
 absorption of cathode rays of different
 velocity in (ROBINSON), A., ii, 93.
 dispersion of (CUTBERTSON and
 CUTBERTSON), A., ii, 561.
 compressibility of (BURT), A., ii, 823.
 solubility of, in water (V. ANTROPPOFF),
 A., ii, 409.
Hellebore group (KELLER), A., ii, 887.
"Helmitol," assay of (HEGLAND), A., ii,
 555.
Hemicellulose, occurrence of, in the
 pods of *Psium sativum* and *Phaseolus*
vulgaris (SCHULZE and PENNINGER),
 A., ii, 889.
Hemielastin (WECHSLER), A., i, 703.
Hemipinic acid, dinitro-, and its
 anhydride and dimethyl ester (WEG-
 SCHEIDER and KLEMENC), A., i, 671.
m-Hemipinic acid, preparation of (LUFF,
 PERKIN, and ROBINSON), T., 1136; P.,
 132.
Hen's eggs. See Eggs.
Hepta-acetyl. See under the parent
 substance.
Heptadecylaniline, and its derivatives
 (LE SUEUR), T., 2435; P., 290.
Heptane, 8-*c*-dibromo-, and 8-hydroxy-
 (KRAPIWIN), A., i, 349.
isoHeptelic acid, α -nitro-, and α -nitroso-,
 ethyl esters (SCHMIDT and HAID), A.,
 i, 813.
Heptylcyclohexene, end its semi-
 carbazone (DARZENS and ROST), A.,
 i, 856.
Heptylidenehydrazine (FRANZEN and
 EICHLER), A., i, 700.
Hesperitin (2:4:6-trihydroxyphenyl
 3-hydroxy-4-methoxystyryl ketone),
 constitution of, and its acetyl deriva-
 tive (TUTIN), T., 2060; P., 222.
Heterocyclic compounds, formation of
 (LE SUEUR and HAAS), T., 173;
 P., 4.
 dimuclear synthesis of (BÜLOW and
 HAAS), A., i, 203.
Heterohydroxylic acids. See Acids.
Hexa-acetatetriamine-trichromic
 iodide (WEINLAND, GUSSMANN, and
 BÜTTNER), A., i, 504.
Hexa-acetatetripyridinetrichromic tri-
 hydroxide, salts of (WEINLAND and
 GUSSMANN), A., i, 504.
Hexa-acetyl. See under the parent
 substance.
Hexa-alkylacetones, fission of (HALLER
 and BAUER), A., i, 300.
¹²**cycloHexadienol**, and its semi-
 carbazone and oxime (KÖTZ and
 GRETHE), A., i, 24.
Hexaglycolatotrichrome base, basic
 glycolate of (CALCAGNI), A., i, 811.
Hexahydro-mesobenzdianthrone, acetyl
 derivative of (POTSCHWALCHER),
 A., i, 495.
Hexahydrocarbazole, benzoyl deriva-
 tive of (V. BRAUN), A., i, 880.
Hexahydrocymene. See *p*-Methylpropyl-
 cyclohexane.
Hexahydropyrene, picrate of (LANG-
 STEIN), A., i, 727.
trans-Hexahydroterephthalic acid, di-
 menthyl ester (RUPE and MÜNSTER),
 A., i, 398.
Hexalacetotrichrome base, salts of
 (CALCAGNI), A., i, 811.
 2:4:5:2':4':5'.Hexamethoxydiphenyl
 (FABINYL and SZÉKI), A., i, 838.
 2:4:5:2':4':5'.Hexamethoxydiphenyl
 acetonitrile (FABINYL and SZÉKI),
 A., i, 838.
Hexamethoxydiphenylmethane, bromine
 derivative of (FABINYL and SZÉKI),
 A., i, 838.
Hexamethyleneimine, constitution of,
 and its benzyl derivative (V. BRAT),
 A., i, 821.
Hexamethylenetetramine, compounds of
 with mercuric chloride, iodide and
 sulphate (SCHMIZ), A., i, 865.
 thiocyanate (CALZOLARI), A., i, 614.
 detection of, in musts and wines
 (BONIS), A., ii, 468, 761; (VOISE-
 NET), A., ii, 466; (SURRÉ), A., ii, 808.
Hexamethylenetetraminetriglycinol
 (HOFMANN, LA ROCHE & Co.), A., i, 378.
Hexamethylphloroglucinol, preparation
 of (HERZIG and ERTHAL), A., i, 667.
Hexan- α diol, synthesis of ethers of
 (DIONNEAU), A., i, 853.
^{cyclo}**Hexan-1:3** dione and its oxime
 (KÖTZ and GRETHE), A., i, 24.
Hexan- β dione *ac*-tricarboxylic acid
 γ -hydroxy-, methyl ester and its
 phenylhydrazone (KOMNENOS), A., i,
 542.
Hexan- β dione-*xy*-tricarboxylic acid,
 methyl ester, and its phenylhydra-
 zone (KOMNENOS), A., i, 542.
Hexane, specific velocity and recombi-
 nation of the ions in (JAFFE), A., i,
 481.
 di-iodo- (DIONNEAU), A., i, 354.
^{cyclo}**Hexane**, derivatives of (KOWLER and
 BURNLEY), A., i, 391.
 its separation from, and estimation in
 mixtures containing benzene (PAR-
 TERTON and FLECK), T., 1773; P.,
 207.

- cyclo*Hexane, 1:3-diamino-, and its platinumchloride (KÖTZ and GRETHE), A., i, 24.
- 1:1-dinitro- (NAMEYKIN), A., i, 329.
- cyclo*Hexanecarboxylic acid 4-oximino-, optically active salts of (MILLS and BAIN), T., 1866; P., 214.
- cyclo*Hexanolpropan-8-ol, dehydration of (TARBOURIECH), A., i, 32.
- cyclo*Hexanone, 2-bromo-, and 2- and 3-chloro- (KÖTZ and GRETHE), A., i, 24.
- 2:6-dioximino-, and the corresponding dibenzoate (BORSCHÉ), A., i, 178.
- cyclo*Hexanone-2-carboxylic acid (GARDNER, FEEKIN, and WATSON), T., 1764; P., 137.
- and its ethyl ester and barium and silver salts (KÖTZ and GRETHE), A., i, 25.
- 1-chloro- and 1-bromo-, ethyl esters (KÖTZ), A., i, 259.
- cyclo*Hexanoneoxime, 3-hydroxyamino- (KÖTZ and GRETHE), A., i, 24.
- cyclo*Hexanon-2-ol (KÖTZ and GRETHE), A., i, 24.
- and β -*cyclo*Hexan-1:2:3 triol, and their salts (BRUNEL), A., i, 477.
- cyclo*Hexenaldehyde, and its semicarbazone (SOBECKI), A., i, 367.
- cyclo*Hexene, Δ^2 -bromo-, and dibromide (SOBECKI), A., i, 367.
- N*-Hexenoic acid, β -amino-, and its benzoyl derivative (POSNER and ROUDE), A., i, 847.
- N*-*cyclo*Hexenone ($\Delta^{1:2}$ -dihydrophenol) (TSCHUGAEFF), A., i, 245.
- N*-*cyclo*Hexen-2-ona-1-carboxylic acid. See $\Delta^{1:2}$ -Dihydrosalicylic acid.
- N*-*cyclo*Hexen-2-one-1-carboxylic acid, and its ethyl ester (KÖTZ and GRETHE), A., i, 25.
- N*-Hexinene-8 ϵ -diol, stereochemical isomeric dibromides and diacetyl derivatives of (DUPONT), A., i, 85.
- and ζ -hexachloro-, and its derivatives (DUPONT), A., i, 379.
- N*-Hexonamide, bromo- (BERGELL and V. WÜLFING), A., i, 304.
- hexoic acid, α -hydroxy- ϵ -benzoylamino-, and its calcium salt, and ϵ -amino- α -hydroxy- (FISCHER and ZEMPLEN), A., i, 101.
- α -nitro-, potassium salt and α -oximino- (SCHMIDT and DIETZLE), A., i, 815.
- hexonitrile (V. BRAUN and TRUMPLER), A., i, 26.
- hexose, fermentation of, in the presence of a phosphate (YOUNG), A., i, 12.
- phosphoric acid ester, and its compounds (V. LEBEDEF, A., i, 716.
- Hexoses, formation of laevulinic acid from (ALBERDA VAN EKENSTEIN and BLANKSMA), A., i, 461.
- cause of the colour reactions of (ALBERDA VAN EKENSTEIN and BLANKSMA), A., i, 762.
- Hexoyl bromide (ANDRÉ), A., i, 563.
- iso*Hexoyl-L-aspartic acid, *d*- α -bromo- (FISCHER and FIEDLER), A., i, 657.
- iso*Hexoyl-L-tyrosine, *d*- α -bromo- (FISCHER and FIEDLER), A., i, 656.
- iso*Hexoyl glycol-L-leucine, *d*- α -bromo- (ABDERHALDEN and WEBER), A., i, 719.
- d*-*iso*Hexoyl glycol-d-isoleucine, α -bromo- (ABDERHALDEN and SCHULER), A., i, 305.
- d*-*iso*Hexoyl-L-isoleucine, α -bromo- (ABDERHALDEN and SCHULER), A., i, 305.
- Hexoylphenylacetylene (ANDRÉ), A., i, 563.
- iso*Hexoyltryptophan, L-bromo- (FISCHER), A., i, 22.
- cyclo*Hexyl disulphide (MAILHE and MURAT), A., i, 374.
- mercaptan and its derivatives (MAILHE and MURAT), A., i, 374.
- cyclo*Hexyl- ψ nitrole (NAMEYKIN), A., i, 329.
- cyclo*Hexylselenol, and its metallic derivatives (MAILHE and MURAT), A., i, 374.
- iso*Hexylamine *iso*hexyldithiocarbamate (KALUZA), A., i, 130.
- cyclo*Hexylbromopropylene (DE RESSEGUIER), A., i, 467.
- cyclo*Hexyldiethylamine picrate (DARZENS), A., i, 63.
- cyclo*Hexyldimethylamine picrate (DARZENS), A., i, 63.
- Hexylene, action of heat on (ENGLER and ROUTALA), A., i, 2.
- Hexylene- α -dithiol and its benzoate (BRAUN), A., i, 14.
- cyclo*Hexylglycollic acid, sodium and silver salts, and its amide (GODCHOR and FREZOUIS), A., i, 480.
- cyclo*Hexyldenetetramethyldiaminodiphenylmethane (WAHL and MEYER), A., i, 134.
- iso*Hexylparabanic acid (KALUZA), A., i, 131.
- cyclo*Hexylpropylene (DE RESSEGUIER), A., i, 467.
- cyclo*Hexylpropylene dibromide (DE RESSEGUIER), A., i, 467.
- 3-*iso*Hexylrhodanic acid (KALUZA), A., i, 130.
- cyclo*Hexyltetrolic acid, and its methyl ester (DE RESSEGUIER), A., i, 467.

- iso*Hexylthiocarbamide (KALUZA), A., i, 131.
- iso*Hexylthiocarbimide (KALUZA), A., i, 131.
- iso*Hexylthioparabanic acid (KALUZA), A., i, 131.
- Hippuric acid, and its amide, action of, with dehydrating agents (MOHR and STROSCHEIM), A., i, 557.
- estimation of, by the formaldehyde titration (HENRIQUES and SÖRENSEN), A., ii, 466.
- estimation of, in urine (HENRIQUES and SÖRENSEN), A., ii, 164.
- Hirudin and mercury (PRUSSAK), A., ii, 229.
- Histidine, bacterial cleavage of (ACKERMANN), A., i, 419.
- the fate of, in the body of the dog (KOWALEWSKY), A., ii, 147.
- cleavage of, in the organism of the dog (ANDERHALDEN, EINBECK, and SCHMID), A., ii, 974.
- action of, with picric acid (BRIGL), A., i, 336.
- d*- and *l*-Histidine anhydrides, and silver and mercury salts of the latter (PAULY), A., i, 336.
- di*- and *tetra*-iodo-, and the disilver salt of the latter (PAULY), A., i, 640.
- Homosanthroic acid, and its silver salt (HELLER and TISCHNER), A., i, 64.
- Homocholine, synthetic (KUTSCHER), A., i, 611.
- Homocholine. See also Trimethylpropylammonium, hydroxy-, chloride.
- Homochromoisomerism (HANTZSCH), A., i, 474, 475; (BUSCH), A., i, 617.
- of azophenols (HANTZSCH), A., i, 790.
- of nitroanilines (HANTZSCH), A., i, 727.
- Homocriodictyol (2,4:6-trihydroxyphenyl 4-hydroxy-3-methoxystyryl ketone), constitution and methyl derivative of (TUTIN), T., 2059; P., 222.
- Homolaevulinic acid semicarbazone (CAMPELL and THORPE), T., 1315.
- Homoveratraldehyde, oxime of (MANICH and JACOBSON), A., i, 169.
- Honduran (TSCHIRCH and WERMÜLLER), A., i, 688.
- Hondurrol and its dibenzoate (TSCHIRCH and WERMÜLLER), A., i, 689.
- β*-Honduroresin (TSCHIRCH and WERMÜLLER), A., i, 688.
- Honduroresinol (TSCHIRCH and WERMÜLLER), A., i, 688.
- Honey, analysis of artificial (MUTTELET), A., ii, 660.
- Hordein, extraction and reactions of (KRAFT), A., i, 792.
- Hordeanine, synthesis of (ROSENFELD), A., i, 241; (LEGER), A., i, 336.
- Hormones, function of, in stimulating enzymic change (ARMSTRONG and ARMSTRONG), A., ii, 883.
- Hornblende, from the Rhön basalts (GALKIN), A., ii, 721.
- Hulsite, composition of (SCHALLER), A., ii, 621.
- Humic acids of grey sand and brown sandstone (HORNBERGER), A., ii, 745.
- Hyacinths, essential oil of (ENKLAAR), A., i, 122.
- Hydantoin, action of hypochlorous acid and its sodium salt on (BILTZ and BEHRENS), A., i, 589.
- derivatives, optically active, catalytic racemisation of (DAKIN), A., i, 596.
- Hydrates, non-dehydration of, by absolute alcohol (SCHREINKMAKERS), A., i, 294.
- See also Salt hydrates.
- Hydration and colour (POMA), A., ii, 487.
- rate of, of acid anhydrides (RIVETT and SIDGWICK), T., 732, 1677; P., 66, 200.
- values, determination of (WOBLET; GLOVER), P., 298.
- Hydrazides, metallic, preparation of (EBLER and KRAUCH), A., ii, 614.
- Hydrazidicarboxylanilide (STOLLE, LEVERKUS, and KRAUCH), A., i, 790.
- Hydrazidicarboxylazoisimide (STOLLE, LEVERKUS, and KRAUCH), A., i, 790.
- Hydrazidicarboxylethylamide (STOLLE, LEVERKUS, and KRAUCH), A., i, 790.
- Hydrazidicarboxylhydrazide, and its derivatives (STOLLE, LEVERKUS, and KRAUCH), A., i, 790.
- Hydrazidicarboxylphenylhydrazide (STOLLE, LEVERKUS, and KRAUCH), A., i, 790.
- Hydrazidines, new method of preparation of (PONZIO), A., i, 443.
- conversion of, into hydrazines (PONZIO), A., i, 699.
- Hydrazine, anhydrous, preparation of (RASCIG), A., ii, 706.
- oxalates (TURRENTINE), A., i, 356.
- silico- and titano-fluorides (EMER and SCHOTT), A., ii, 605.
- Hydrazines, behaviour of, in the sulphite reaction (BRÜCHER and SONNENBURG), A., i, 144.
- auto-reduction of (CHAFFAWAY and ALDRIDGE), P., 325.
- conversion of hydrazidines into (PONZIO), A., i, 699.
- primary, function of the nitrogen atoms in (RISCH), A., i, 75.

- 6-Hydrozobenzamide (HELLER and WEIDNER), A., i, 536.
- Hydrazobenzene, *hexanitro-* (HANTZSCH and LISTER), A., i, 526.
- Hydrazodiphenylethane (DUVAL), A., i, 646.
- 2,2'-Hydrazodiphenylmethane-4,4'-dicarboxylic acid, ethyl ester (DUVAL), A., i, 560.
- Hydrazomethane, nitroso- (THIELE), A., i, 889.
- Hydrazone, $C_{16}H_{22}N_2$, from glyoxal and diphenylmethanediethyldihydrazine (V. BRAUN), A., i, 525.
- $C_{26}H_{44}O_{10}N_4$, from mannose and diphenylmethanediethyldihydrazine (V. BRAUN), A., i, 525.
- Hydrazones (TRÖGER and WESTERKAMP), A., i, 207.
- formation of (GRASSI), A., i, 890.
- influence of the halogens on phototropy in (GRAZIANI), A., i, 777.
- Hydrindene, 1-imino-2-cyano- (MITCHELL and THORPE), T., 2276.
- Hydrindene-2-carboxylic acid, 1-imino-, ethyl ester (MITCHELL and THORPE), T., 2271; P., 249.
- Hydrindone, preparation of (MITCHELL and THORPE), T., 2274.
- 2-cyano-, and its derivatives (MITCHELL and THORPE), T., 2277.
- 2-nitro-, and its derivatives (THIELE and WEITZ), A., i, 855.
- 1-Hydrindone-2-carbanilide (MITCHELL and THORPE), T., 2274.
- 1-Hydrindone-2-carboxylic acid, ethyl ester, and its derivatives (MITCHELL and THORPE), T., 2273; P., 249.
- Hydriodic acid. See under Iodine.
- Hydroacridines, formation of (POPE and HOWARD), T., 78, 972; P., 83.
- Hydroaromatic compounds (BRITISH ASSOCIATION REPORTS), A., i, 549.
- Hydrobenzoin-*o*-dialdehyde, and its phenylhydrazones (THIELE and WEITZ), A., i, 855.
- Hydrobromic acid. See under Bromine.
- Hydrocarbon, (C_3H_4) , from Honduras balsam (TSCHIRCH and WERDMÜLLER), A., i, 683.
- C_9H_{14} , from cyclohexanolpropan- β -ol (TAREOURIECH), A., i, 32.
- C_9H_{20} , from methyl nonyl ketone (HALLER and LASSIEUR), A., i, 355.
- $C_{10}H_{18}$, from isothujene (KONDAROFF and SKWORZOFF), A., i, 755.
- $C_{10}H_{18}$, from carvomenthol (BRUNEL), A., i, 479.
- $C_{11}H_{18}$, from sandalwood (SCHIMMEL & Co.), A., i, 758.
- $C_{12}H_{18}$, from γ -phenyl- $\beta\beta$ -dimethylbutan- γ -ol (LUCAS), A., i, 378.
- Hydrocarbon, $C_{10}H_{18}$, from 1:3 dimethyl- Δ^3 -cyclohexene-5-trimethylcarbinol (AUWERS and PETERS), A., i, 842.
- $C_{17}H_{28}$, from $\gamma\gamma$ -diphenyl- $\beta\beta$ -dimethylpropan- γ -ol (LUCAS), A., i, 378.
- $C_{18}H_{20}$, from $\gamma\delta$ -diphenyl- $\beta\beta$ -dimethylbutan- γ -ol (LUCAS), A., i, 378.
- $C_{19}H_{22}$, from phenylidicyclohexylcarbinol.
- $C_{21}H_{30}$, from benzophenone and ethylbenzene (CIAMICIAN and SILBER), A., i, 489.
- $C_{27}H_{40}$, from *Tussilago farfara* (KLOBB, GARNIER, and EHRWEIN), A., ii, 1101.
- $C_{28}H_{38}$, from *Antennaria dioica* (KLOBB, GARNIER, and EHRWEIN), A., ii, 1101.
- $C_{28}H_{38}$, from *Tilia europaea* (KLOBB, GARNIER, and EHRWEIN), A., ii, 1101.
- $C_{29}H_{40}$, from *Matricaria chamomilla* (KLOBB, GARNIER, and EHRWEIN), A., ii, 1101.
- $C_{30}H_{42}$, from *Arnica montana* (KLOBB, GARNIER, and EHRWEIN), A., ii, 1101.
- $C_{32}H_{46}$, from *Artemisia maritima* (KLOBB, GARNIER, and EHRWEIN), A., ii, 1101.
- Hydrocarbons, $C_{10}H_{18}$, from the union of camphene and pinene with hydrogen (VAVON), A., i, 52.
- $C_{10}H_{18}$, molecular refraction of (RONLAND), A., ii, 809.
- formation of, in nature (ENGLER), A., i, 160.
- preparation of, by the action of ammonium sulphide on aliphatic aromatic ketones (WILLGERODT and SCHOETZ), A., i, 392.
- from wool grease oleins (GILL and FORREST), A., i, 705.
- of vegetable origin (KLOBB, GARNIER, and EHRWEIN), A., ii, 1100.
- action of, on ketones and aldehydes under the influence of sunlight (PATERNO and CHIEFFI), A., i, 41.
- aromatic, nitro-derivatives, compounds of aluminium chloride with (MENSCHUTKIN), A., i, 234.
- saturated, action of nitric acid on (NAMETKIN), A., i, 829.
- unsaturated, action of acetyl halides on, in the presence of aluminium halides (KRAPIVIN), A., i, 349.
- relation between constitution and heats of combustion of (AUWERS and ROTH), A., ii, 485.
- hydroaromatic unsaturated (AUWERS and PETERS), A., i, 826, 827.
- improvement in Fresenius' method for estimating (HENFICH), A., ii, 355.

- Hydrocellulose** (JENTGEN), A., ii, 854; (SCHWABER), A., i, 817.
- Hydrochloric acid**. See under Chlorine.
- Hydrocyanic acid**. See under Cyanogen.
- Hydrofluoric acid**. See under Fluorine.
- Hydrogel and hydrosol**, formation of (LOTTERMOSER), A., ii, 278.
- Hydrogels**, moulding of, by crystals (LIESEGANG), A., ii, 835.
- Hydrogen**, atomic weight of (JONES), A., ii, 404.
- refraction and dispersion of (CUTHBERTSON and CUTHBERTSON), A., i, 85.
- spectrum of (HICKS), A., ii, 86.
- canal-rays of, positive and negative ions in (WIEN), A., ii, 475.
- luminous, emission and absorption of (LADENBURG), A., ii, 811; (PFLÜGER), A., ii, 1015.
- diffuse nascent, behaviour of (VOURNASOS), A., ii, 286.
- flames, ions analogous to those of Röntgen rays, produced by (DE BROGLIE), A., ii, 769.
- adsorption of, by carbon (MCBAIRN), A., ii, 21.
- synthesis of volatile compounds of (VOURNASOS), A., ii, 948.
- action of, on carbon monoxide (GAUTIER), A., ii, 708.
- and carbon, the direct union of (PRINGS), T., 498; P., 55; (BONE and COWARD), T., 1219; P., 146.
- and chlorine, interaction of (MACMAHON), T., 845; P., 58, 93.
- and nitrogen, compression of a mixture of (BRINER and WKOCZYNSKI), A., ii, 707.
- and oxygen, the union of, in flame (DIXON), T., 661.
- Hydrogen arsenide**. See Arsenic trihydride.
- bromide. See under Bromine.
- chloride. See under Chlorine.
- fluoride. See under Fluorine.
- iodide. See under Iodine.
- peroxide, formation of (CHARITSCHKOFF), A., ii, 1054; (CHARITSCHKOFF and ANBARANOFF), A., ii, 1055.
- anodic formation of (RICHARZ), A., ii, 27.
- preparation of pure (SCHNATOLLA), A., ii, 1054.
- influence of persulphates on the oxidation of, with permanganate (FRIEND), P., 88.
- action of, on silver bromides (TRIVELLI), A., ii, 502.
- Hydrogen peroxide**, new reagent for (CHARITSCHKOFF), A., ii, 238.
- volumetric estimation of, in presence of persulphuric acid (SKRABAI and VACEK), A., ii, 447.
- sulphide, refraction and dispersion of (CUTHBERTSON and CUTHBERTSON), A., i, 85.
- action of, on white lead (SACHER), A., ii, 712.
- new apparatus for generating (UNRASCHE), A., ii, 949.
- precipitation of metals by (BRUNER and ZAWADSKI), A., ii, 944, 945.
- Hydrogen**, delicate reaction for (ZEXGELIS), A., ii, 1106.
- estimation of, by catalytic absorption (PAAL and HARTMANN), A., ii, 237.
- Hydrogen electrode**. See Electrode under Electrochemistry.
- Hydrogen ion**, concentration of, in seawater (SØRENSEN and PALITZSCH), A., ii, 404.
- concentration of, in solutions of phosphoric acid and sodium hydroxide (RINGER), A., ii, 396.
- Hydrogibbsite**, occurrence of (WELLS), A., ii, 965.
- Hydrolysis**. See under Affinity, chemical.
- Hydromolybdicyano acid**. See under Molybdenum.
- Hydonaphthalene derivatives**, heat of combustion of (LENGUE), A., ii, 898.
- Hydropiperic acid**, β -amino, and its benzoyl derivatives (POSNER and RONDE), A., i, 847.
- Hydropyrindole** (PILOTY), A., i, 277.
- Hydrosol and hydrogel**, formation of (LOTTERMOSER), A., ii, 278.
- Hydroxorbhydroxamoxine**, β -hydroxyamino-, hydroxide (POSNER and RONDE), A., i, 847.
- Hydroxosorbic acid**, amino-. See Δ^2 -Hexenoic acid, β -amino-.
- Hydroxamic acids**, preparation of (JONES and OESPER), A., i, 13.
- electrical conductivity of (QUINPER and MANDALL), A., ii, 482.
- Hydroxy-acids**, aliphatic, preparation of (IMBERT and CONSORTIUM DES ELEKTROCHEMISCHEN INDUSTRIE), A., i, 7.
- formation of, during autolysis of the liver (KONDO), A., ii, 791.
- manganese salts of (TAMM), A., ii, 855.
- β -unsaturated, mechanism of the transformation of, into the isomeric γ -ketonic acids (FRIELENHETER), A., i, 175.
- Hydroxy-acids**, synthesis of (DETTON), A., i, 458.

- Hydroxy-compounds**, aliphatic, action of oxygen on, in the presence of copper (TRAUBE), A., i, 294.
 aromatic, action of sulphites on (BUCHNER and SONNENBURG), A., i, 144.
Hydroxy-iminic acids, preparation of substituted (CUSMANO), A., i, 50.
Hydroxy-ketones (*acylones*), condensation of sodium derivatives of, with esters of the acetic series (BOUVEAULT and LOCQUIN), A., i, 92.
Hydroxylamine salts, dissociation of, in aqueous solution (BARRETT), P., 233.
Hydroxylamines and α -hydroxylaminoximes, alicyclic, behaviour of towards nitrous acid (CUSMANO), A., i, 182.
Hydroxylaminedisulphonates of the alkaline earth metals, preparation of (RASCHIG), A., ii, 411.
Hyoscyamine, specific rotatory power of (CARR and REYNOLDS), T., 1328; P., 180.
Hypophosphoric and Hypophosphorous acids. See under Phosphorus.
Hypoxanthine, and the relationship of adenase to its origin in the organism (VÖGTLIN and JONES), A., ii, 631.
Hyasop oil, β -pinene and β -pinocampnone from (GILDEMEISTER and KÖHLER), A., i, 180.
- I.**
- Ice**, colloidal (V. WEIMARN and OSTWALD), A., ii, 400; (V. WEIMARN), A., ii, 404.
 and water, vapour pressure of (NERNST), A., ii, 826.
 water and water vapour, specific heat of (NERNST), A., ii, 844.
Nicotides mucronata, fruit of (WILCOX), A., ii, 441.
Illuminating gas. See under Gas.
Imenite, estimation of titanic acid in (RÖDER), A., ii, 78.
Iminezoles, complex (MELDOLA and KUNTZEN), P., 340.
 β -Iminazolyethylamine. See Ethylglyoxaline, 4- β -amino-
Imines, cyclic (V. BRAUN), A., i, 821.
 cyclic, decomposition of, by means of sodium hypochlorite (BILTZ and BEHRENS), A., i, 594.
 β -Iminoacetic butyric acid, and its hydrochloride (STADNIKOFF), A., i, 825.
 β -Iminoacetic butyric acid, diethylester (STADNIKOFF), A., i, 825.
Imino-chlorides, reactions of, with salts of organic acids and with potassium cyanide (MUMM and HESS), A., i, 311.
Imino-compounds, formation and reactions of (MITCHELL and THORPE), T., 1997, 2261; P., 114, 248; (CAMPBELL and THORPE), T., 1299; P., 176.
Imino-ethers, formation of (MATSUI), A., i, 695.
Imino-group, formation of a six-membered ring by means of the (THORPE and THORPE), P., 235.
Iminothiocarbonic esters of the aliphatic series (DELÉPINE), A., i, 613.
Immedial-indone, probable constitution of (FRANK), T., 2044; P., 218.
Imperatoria, constituents of the rhizome of (HERZOG and KROHN), A., i, 124.
Incarnatrin (ROGERSON), T., 1008; P., 112.
Incarnatyl alcohol (ROGERSON), T., 1011; P., 112.
Incarnatylphthalic acid, sodium salt (ROGERSON), T., 1011.
Indazocarboxylonitrile (PSCHORR and HOPPE), A., i, 737.
Indazole, trichloro-3-hydroxy- (FREUNDLER), A., i, 133.
1-Indenone-2-aldehyde, 3-hydroxy- (FELIX and FRIEDLÄNDER), A., i, 273.
Indican, preparation of (TER MEULEN), A., i, 54.
 scatole and iodine, differentiation between, in Jaffé's indican reaction (SPIETHOFF), A., ii, 508.
Indicator, very sensitive (SACHER), A., ii, 1106.
 new, for acidimetry and alkalinity (MELLER), A., ii, 995.
 of Ruppe and Loose (V. OSTROMISSENSKY and BARADSCHAN), A., ii, 1106.
 dimethyl-brown, a new (POZZI-ESCHOT), A., ii, 153.
 α -naphtholphthalein, a new (SØRENSEN and PALITZSCH), A., ii, 446.
Indicators (WALFOLE), A., ii, 995.
 theory of (NOYES), A., ii, 746.
 influence of neutral salts on (MICHAELIS and RONA), A., ii, 153.
Indigoid dyes (FELIX and FRIEDLÄNDER), A., i, 278.
 of the anthracene series (BEZDZIK and FRIEDLÄNDER), A., i, 189.
Indigotin, action of primary amines on (GRANDMOUGIN), A., i, 438.
 decomposition of, by alkalis (FRIEDLÄNDER and SCHWENK), A., i, 592.
Indigotin, di- and tribromo-, sulphides (CASSELLA), A., i, 438.
5:7:5':7'-tetrabromo- (GRANDMOUGIN), A., i, 74; (DANAILA), A., i, 137.
4:5:7:4':5':7'-pentabromo-, and **4:5:7:4':5':7'-hexabromo-** (GRANDMOUGIN), A., i, 339.

- Indigotin**, 5:7:5':7'-tetrachloro-, synthesis of (OBERREIT), A., i, 201; (DANAÏLA), A., i, 137.
- Indigotine**, preparation of leuco-derivatives of (MERCK and FLIMM), A., i, 438.
- Indigotin group**, compounds of, with triphenylmethane dyes (REITZENSTEIN and BREUNING), A., i, 439.
- Indigotindianilide**, hydrochloride and sulphate (GRANDMORGIN and DES-SOULAVY), A., i, 73.
- Indigo white**, condition of, in aqueous solutions (KNECHT and BATEY), A., i, 593.
- Indirubin** (BLOXAM and PERKIN), T., 1460; P., 163.
constitution of (MALLARD), A., i, 138.
decomposition of, by alkalis (FRIEDLÄNDER and SCHWENK), A., i, 592.
- Indirubin-2-anil**, and its hydrochloride (PUMMERER and GÖTTLER), A., i, 512.
- Indium**, moniodide, monosulphide, selenide and telluride (THIEL and KOELSCH), A., ii, 413.
- Indium alloys** with mercury, electrochemical investigation of (RICHARDS and WILSON), A., ii, 384.
- Indium**, estimation of, by electrolytic means (KOLLOCK and SMITH), A., ii, 1000.
- Indole**, 2-amino-, and its diacetyl derivative, and 2-acetylamino- (PSCHORR and HOPPE), A., i, 737.
- Indoles**, substituted, preparation of (ARBUOFF and TICHWINSKY), A., i, 771.
substituted, preparation of, from benzoin and secondary arylamines (RICHARDS), T., 977; P., 92.
- Indole-3-aldoxime** (PSCHORR and HOPPE), A., i, 737.
- Indole-3-carboxylnitrile**, and its acetyl derivative (PSCHORR and HOPPE), A., i, 737.
- Indolinones**, preparation of (BOEHRINGER & SÖHNE), A., i, 429.
- Indoxyl** and its derivatives, preparation of (BADISCHE ANILIN- & SODA-FABRIK), A., i, 428.
estimation of, in urine (MENNECHET), A., ii, 83.
- Indoxyl-2-aldehyde** (FRIEDLÄNDER and SCHWENK), A., i, 592.
- 2-(2')-Indoxyl-1:3-indandione** (FELIX and FRIEDLÄNDER), A., i, 278.
- 2-(2')-Indoxyl-3-indanone** (2-indane-2-indole-indigo) (FELIX and FRIEDLÄNDER), A., i, 278.
- 4-(2')-Indoxyl-3-methyl-4-pyrazole** (FELIX and FRIEDLÄNDER), A., i, 280.
- 5-(2')-Indoxylpyrimidine-2:4:6-trione** (FELIX and FRIEDLÄNDER), A., i, 280.
- 3-(2')-Indoxyl-3-isoquinoline-1:4-dione** (FELIX and FRIEDLÄNDER), A., i, 279.
- Infant**, gaseous metabolism of. See under Metabolism.
- Inorganic compounds**, formulation and nomenclature of (HOFFMANN), A., ii, 196.
- Inosic acid** and carnine (HAISEL and WENZEL), A., i, 543.
- Inositol** (*inosite*) (ROSENBERGER), A., ii, 325.
detection of (MELLÈRE and FLEURY), A., ii, 553.
detection of, as a means of identifying wine vinegar (FLEURY), A., ii, 1006.
- Inositol-diphosphoric acid**, and its barium salt (CONTARDI), A., i, 157.
- Insane**, effect of electric bath treatment of the, on the urinary creatinine (WALLIS and GOODALL), A., ii, 686.
- Internal pressure**, connexion of surface tension with, and van der Waals' constants a and b (TRAUBE), A., ii, 20.
- Intestinal flora**, influence of dietary alternations on (HESTER and KENDALL), A., ii, 323.
membrane, factors influencing diffusion through fresh (MAYERHOFER and PRIBHAM), A., ii, 428.
influence of sugar on the permeability of the (MAYERHOFER and STEIN), A., ii, 974.
imbibition of, with sodium sulphate solutions (QUAGLIARIELLO), A., ii, 974.
- Intestine**, physiology of movements and digestion in the (RAUENSTARK and CONNHEIM), A., ii, 518.
laxatives and the calcium of the (CHIARI), A., ii, 1088.
protein degradation in the human (STAUBER), A., ii, 627.
small, gaseous metabolism of the (BRODIE and VOGT; BRODIE, CULLIN, and HALLIBURTON), A., ii, 518.
tonus of the, influence of bile and bile salts on the (D'ERRICO), A., ii, 729.
- Intramolecular transformations** (DUBROTH, AICKELIN, BRAHN, FESTER, and MERCKLE), A., i, 518.
- Inulin**, digestion of (BISSET), A., ii, 224.
- Invertase** (v. EULER, LINDBERG, and MELANDER), A., i, 907.
from malt extracts (VANDELVEDE), A., i, 798.
effect of alcohol on (HUDSON and PAINE), A., i, 798.
destruction of, by acids and alkalis (PAINE), A., i, 601.
influence of acids and alkalis on (HUDSON and PAINE), A., i, 797.

- Invertase, inversion of sucrose by (HUDSON and PAINE; MASUDA), A., i, 601.
- use of, in determining the alkalinity or acidity of biological fluids (HUDSON and SALANT), A., ii, 764.
- Invert sugar. See Sugar, invert.
- Iodobiose (WEYL), A., i, 792.
- q.v.* Iodalbumose (WEYL), A., i, 792.
- Iodates. See under Iodine.
- Iodine, constitution of, in solution (WAENTIG), A., ii, 117.
- hydrolysis of (BRAY), A., ii, 819.
- as a cryoscopic solvent (OLIVARI), A., ii, 18, 582.
- distribution of, between organic solvents (LANDAU), A., ii, 593.
- saturated compounds of, absorption spectra of (CRYMBLE, STEWART, and WRIGHT), A., ii, 470.
- adsorption of, by solids (SIEGRIST), A., ii, 486; (GUICHARD), A., ii, 772.
- solutions, colour of (HILDEBRAND), A., ii, 1055.
- ultra-microscopy of (AMANN), A., ii, 496, 844.
- vapour, electrical behaviour of fluorescing (WEIDINGTON), A., ii, 6.
- action of, on sodium dithionite or trithionate (MÜLLER), A., ii, 154.
- action of, with ketones (DAWSON and WHEATLEY), T., 2048; P., 233.
- complex in sponges (WHEELER and MENDEL), A., ii, 143.
- and potassium iodide, solubility of, in aqueous-alcoholic solutions (PARSONS and CORLISS), A., ii, 1061.
- Hydriodic acid (*hydrogen iodide*) heat of formation of, from the elements (STEGMÜLLER), A., ii, 269.
- dissociation of, at high temperatures (V. FALCKENSTEIN), A., ii, 27, 396.
- oxidation of, under the influence of light (SCHWEZOFF), A., ii, 1020.
- and bromic acid, reaction between, in the presence of a large amount of hydrochloric acid (RANDALL), A., ii, 542.
- Iodides, compounds of, with mercuric iodide and ether (MARSH), T., 2305.
- aliphatic, and silver salts, kinetics of the reaction between (DONNAN and POTTS), T., 1882, P., 212.
- organic, preparation of, from the corresponding bromides and chlorides (FINKELSTEIN), A., i, 453.
- estimation of, in the presence of chloride, bromide, or free iodine (BRAY and MACKEY), A., ii, 996.
- dates, behaviour of, towards reducing agents (VITALI), A., ii, 496.
- Iodine, reaction for starch (HARRISON), P., 252.
- indican and scatole, differentiation of, in Jaffe's indican reaction (SPIERHOFF), A., ii, 808.
- estimation of (WINTERSTEIN and HERZFELD), A., ii, 68; (HUNTER), A., ii, 650.
- Weszelzsky's method of estimating (CASARES GIL), A., ii, 1107.
- estimation of, in the presence of bromides and chlorides (DIBBIN and COOPER), A., ii, 448.
- in organic substances (PAOLINI), A., ii, 68.
- in the thyroid (SEIDELL), A., ii, 69.
- in protein combinations (RIGGS), A., ii, 650.
- combined, gravimetric estimation of, by means of metallic silver (PEIKINS), A., ii, 542.
- Iodoxy. See under the parent Substance.
- Ionic equilibrium. See under Electro-chemistry.
- Ions and Ionisation. See under Electro-chemistry.
- Ipomoea horsfalliae*, chemical examination of the tuberous root of (POWER and ROGERSON), A., ii, 885.
- Iridium, complex derivatives of (VEZES and DUFFOUR), A., i, 540; (DUFFOUR), A., i, 541.
- Iridium chlorides, compounds of, with silver and thallium (DELEPINE), A., ii, 34.
- disulphates, metallic (DELEPINE), A., ii, 44.
- Iridiodichlorodinitro-oxalic acid, metallic salts of (VEZES and DUFFOUR), A., i, 540; (DUFFOUR), A., i, 541.
- Iron, meteoric, stability or metastability of (GUERTLER), A., ii, 833.
- native, isolation of, from basalt (SEEBACH), A., ii, 963.
- pure, electrolytic preparation of (ANBERG), A., ii, 414.
- content in the human organs (MAGNUS-LEVY), A., ii, 426.
- amount of, in organs in pernicious anemia (RYFFEL), A., ii, 329.
- crystalline structure of, at high temperatures (ROSENHAIN and HUMFREY), A., ii, 128.
- flame spectrum of (HERMSALECH and DE WATTEVILLE), A., ii, 172.
- the magnetic properties of modifications of (HILPERT), A., ii, 579.
- potential of (LAMB), A., ii, 925.
- passivity of (KRASSA), A., ii, 129.
- passivity of, influence of the magnetic field on the (BYERS and DARRIN), A., ii, 579.

- Iron**, electrolytic deposition of (FRATZ), A., ii, 414.
 electrodes. See Electrodes under Electrochemistry.
 cementation of, by solid carbon (CHARPY and BONNETOT), A., ii, 215.
 the system nickel and (RUFER and SCHÜTZ), A., ii, 959.
 crystallography of the system, carbon and (KROLL), A., ii, 1070.
 influence of sulphur on the system, carbon and (LIESCHING), A., ii, 1070.
 the system, copper, nickel and (VOGEL), A., ii, 616.
 influence of antimony and tin on the system, carbon and (GORRENS and ELLINGEN), A., ii, 298.
 rusting of (LAMBERT and THOMSON), T., 2426; P., 290.
 action of steam on (FRIEND), A., ii, 414.
 action of air and steam on, and rusting of (FRIEND), A., ii, 39.
 retardation of the oxidation of, by chromic chloride (ROHLAND), A., ii, 129.
 and steel, the action of pure air and water on (FRIEND), P., 179.
 behaviour of, with stannous salts (THIEL and KELLER), A., ii, 962.
 formation of silicon sulphide in the desulphurisation of (FELDING), A., ii, 32.
 and its oxides, action of, on mixtures of carbon monoxide and carbon dioxide with hydrogen (GAUTIER and CLAUSMANN), A., ii, 855.
 and its oxides, action of, on carbon monoxide at a red heat (GAUTIER and CLAUSMANN), A., ii, 709.
Iron alloys, with carbon (WIGST), A., ii, 414.
 the equilibrium diagram of (HEYN), A., ii, 298.
 decarburisation of, by gaseous oxidising agents (HOCKER), A., ii, 293.
 with manganese and carbon (ARNOLD and READ), A., ii, 1071.
 with phosphorus (KONSTANINOFF), A., ii, 130; (KÜHN), A., ii, 131.
 with tungsten, with molybdenum, and with vanadium, estimation of carbon and sulphur in (MÜLLER and DIERHELM), A., ii, 1110.
 rapid estimation of carbon in (AVERRO), A., ii, 896.

 static (SMITH and MENZIES), A., ii, 1036.
Itaconic anhydride, rate of hydration of (RIVETT and SINGWICK), T., 1677; P., 200.
- J.
- Jam**, estimation of salicylic acid in (v. FELLEBERG), A., ii, 906.
Jarosite, identity of pastrets with (AZEMA), A., ii, 720.
Jasmine oil (ELZE), A., i, 637.
Java Canang oil (ELZE), A., i, 688.
Joaquinite (LOUDBERBACK and BLANDALE), A., ii, 310.
Juniperic acid, constitution of (BOUGAULT), A., i, 297.

K.

Kamala and its constituents, physiological action of (SEMPER), A., ii, 797.

Kaolin, action of acetic acid on (VAN DER LEEDEN), A., ii, 621.

Ketabolism of amino-acids (FLATOW), A., ii, 321.

Kephalin (FARNAS), A., i, 4.

Kephalinic acid and its methyl ester (FARNAS), A., i, 4.

Kermes (*Coccus ilicis*), colouring matter of (DIMROTH), A., i, 487.

Kermesic acid, and its salts, acetyl derivative, and methyl ether (DIMROTH), A., i, 487.

Ketan, preparation of (SCHMIDLIN and BERGMANN), A., i, 816.

polymerisation of (CHICK and WILSMORE), T., 1978; P., 217.

some reactions of, and its combination with hydrocyanic acid (DEAKIN and WILSMORE), T., 1968; P., 216.

Ketens (STAUDINGER and BUCHWITZ), A., i, 46; (STAUDINGER and BEREA), A., i, 89; (STAUDINGER, KLEVER, and KOBER), A., i, 586.

preparation of transformation products of (SCHROETER), A., i, 431.

2-Keto-3-acetoxy-4:5-diphenylene-2:3-dihydrofuran-3-carboxylic acid, ethyl ester (RICHARDS), T., 1457; P., 195.

Keto-alcohols, preparation of (FARBEN-FABRIKEN VORM. F. BAYER & Co.), A., i, 706.

Ketoanilindiphenyltetrahydrotriazine (KÜHLING), A., i, 780.

Keto-anils (BUSCH and FALCO), A., i, 747.

Keto-asarone, and its semicarbazone (PAOLINI), A., i, 391.

2-Keto-3-benzoylcarbamyl-5-chloromethyltetrahydro-oxazole (JOHNSON and GUFST), A., i, 886.

4-Keto-2-benzyl-4:5-dihydroglyoxaline, and its derivatives (FINGER and ZEH), A., i, 591.

2-Keto-3:3-bis(hydroxyphenyl)-4:5-diphenylpyrrolone (RUHEMANN), T., 465.

α -Ketobutyric acid, β -cyano-, and its ethyl ester, and its metallic salts, and derivatives (WISLICENTIS and SILBERSTEIN), A., i, 538.

α -Ketobutyrohydrazide, β -cyano-, hydrazones of (WISLICENTIS and SILBERSTEIN), A., i, 539.

2-Keto-4-carbethoxy-1-methyltetrahydro-pyrrolidene-5- α -propionic acid, 4-cyano-, ethyl ester (CAMPBELL and THORPE), T., 1315.

2-Keto-4-carbethoxytetrahydro-pyrrolidene-5- α -propionic acid, 4-cyano-, ethyl ester and its silver and potassium salts (CAMPBELL and THORPE), T., 1314.

γ -Ketodecic acid, metallic salts and derivatives of (BLAISE and KOEHLER), A., i, 298.

1-Keto-8:7-dimethoxy-2-methyltetrahydroisoquinoline hydrate (PYMAN), T., 270.

2-Keto-4:5-diphenylene-2:3-dihydrofuran (RICHARDS), T., 1458; P., 195.

2-Keto-4:5-diphenylpyrrolone, 3-benzoylamino-3-hydroxy- (RUHEMANN), T., 463.

4-Keto-2:6-dithioacetonylpenthiophen-3:5-dicarboxylic acid, ethyl ester (APITZSCH and KELBER), A., i, 410.

1-Keto-2-ethyltetrahydroisoquinoline, 6:7-dihydroxy- (PYMAN), T., 274.

α -Ketoheptic acid, its ethyl ester and their semicarbazones (BLAISE and KOEHLER), A., i, 298.

α -Ketohexahydrobenzylidene- α -amino-phenol (BORSCH, SCHMIDT, TIEDTKE, and ROTTSCHEPPE), A., i, 881.

α -Ketohexahydrobenzylideneaniline (BORSCH, SCHMIDT, TIEDTKE, and ROTTSCHEPPE), A., i, 881.

α -Ketohexahydrobenzylideneaniline- β -sulphonic acid and its salts (BORSCH, SCHMIDT, TIEDTKE, and ROTTSCHEPPE), A., i, 881.

Ketohydrindenophenazine (RUHEMANN), T., 1449.

6-Keto-11-hydroxyphenyl-6:11-dihydronaphthacene, 5:12-dihydroxy-, and its triacetate and acetyl derivative (VOWINCKEL and DE WEEERTH), A., i, 50.

1-Keto-2-indoxylantracene, and 5- and 8-hydroxy- (BEZMIK and FRIEDLÄNDER), A., i, 190.

2-Keto-1-indoxylantracene (BEZMIK and FRIEDLÄNDER), A., i, 190.

3-Keto-4(2')-indoxyl-1-phenyl-3-methylpyrazole (FELIX and FRIEDLÄNDER), A., i, 279.

Ketols, action of methyl *tert*-butylketone on (BOON), T., 1256; P., 94.

4-Keto-5-methoxydehydrocamphoric acid, methyl ester (KOPPEL), A., i, 51.

1-Keto-6(or 7)-methoxy-2-methyltetrahydroisoquinoline, 7(or 6)-hydroxy-, and its sodium salt (PYMAN), T., 271.

1-Keto-2-methyltetrahydroisoquinoline, 6:7-dihydroxy- (PYMAN), T., 271.

α -Keto-8-methylvaleric acid, β -cyano-, ethyl ester (WISLICENTIS and SILBERSTEIN), A., i, 539.

- Ketone**, C_3H_6O , from cyclopropane and acetyl bromide and its semicarbazone (KRAPIWIN), A., i, 349.
- C_3H_6O , from semicarbazone of ketone C_3H_6O (KRAPIWIN), A., i, 349.
- $C_6H_{10}O_2$, from *d*-lauroleone and its semicarbazone (NOYES and DERICK), A., i, 754.
- $C_7H_{12}O$, from Δ^6 -heptylene and acetyl chloride and its semicarbazone (KRAPIWIN), A., i, 349.
- $C_{15}H_{16}O$, from the action of light on camphor, and its semicarbazone (CIAMICIAN and SILBER), A., i, 496.
- $C_{10}H_{16}O$, from action of magnesium *tert*-butyl chloride on ethyl oxalate (EGOROVA), A., i, 91.
- $C_{14}H_{18}O_3Cl_2$, from picrotoxin and hydrochloric acid (ANGELICO), A., i, 577.
- $C_{14}H_{16}O_3$, from reduction of α -picrotinic acid, and its oxime (ANGELICO), A., i, 577.
- $C_{14}H_{16}O_3$, and its derivatives, from α -picrotinic acid (ANGELICO), A., i, 405.
- $C_{15}H_{20}O$, from α - and β -gurjunene, and its oxime (DEUSSEN and PHILIPP), A., i, 575.
- $C_{17}H_{26}O_3N$, and its derivatives from β -ethylthiomorphide (PSCHORR and HOPPE), A., i, 423.
- $C_{18}H_{26}O_3N$, and its derivatives, from β -ethylthiocodide hydrochloride (PSCHORR and KRECH), A., i, 422.
- $C_{19}H_{28}O_4NS$, from β -methylthiocodide and hydrochloric acid (PSCHORR and KRECH), A., i, 422.
- $C_{19}H_{26}O_3NS$, and its oxime hydrochloride, from ethyl thiomorphide (PSCHORR and HOPPE), A., i, 423.
- $C_{20}H_{28}O_4NS$, and its derivatives from β -ethylthiocodide (PSCHORR and KRECH), A., i, 422.
- Ketones**, synthesis of, by means of organo-magnesium compounds (SALKIND and BEBRISCHWILL), A., i, 11.
- catalytic preparation of (SENDERENS), A., i, 11, 179.
- decomposition of, by ultra-violet light (BERTHELOT and GAUDECHON), A., i, 814.
- reactivity of, towards iodine (DAWSON and WHEATLEY), T., 2048; P., 233.

- Lead alloys with bismuth, analysis of (LITTLE and CARMEN), A., ii, 755.
- Lead alloys with cadmium and bismuth (BARLOW), A., ii, 1066.
- equilibrium in the ternary system, cadmium, mercury and (JANECKE), A., ii, 699.
- with mercury, electrochemical investigation of (RICHARDS and GARROD-THOMAS), A., ii, 384.
- with tin, heat of solidification of (GUERTLER), A., ii, 126; (MAZZOTTO), A., ii, 690.
- Lead acetate, ionisation in aqueous solutions of (JAQUES), A., ii, 387.
- arsenate in viticulture (MOREAU and VINET), A., ii, 443.
- carbonates, basic (FALK), A., ii, 1067.
- Lead hydroxycarbonate (*white lead*), action of hydrogen sulphide on (SACHER), A., ii, 712.
- influence of light on blackened (TAUBER), A., ii, 955.
- chromate, solubility of, in hydrochloric acid (BECK and STEGMÜLLER), A., ii, 1067.
- hydroxide, equilibria in the precipitation of (HERZ), A., ii, 1067.
- peroxide, use of, in organic combustions (WEIL), A., ii, 242; (DENNSTEDT and HASSLER), A., ii, 547.
- Triplumbic tetroxide (*red lead*) (MILBAUER), A., ii, 294.
- silicates, in relation to pottery manufacture (THORPE and SIMMONDS), T., 2282; P., 254.
- fused, crystallisation of (HILPERT and NACKEN), A., ii, 955.
- sulphate, solubility of, in hydrochloric acid (BECK and STEGMÜLLER), A., ii, 1067.
- ferriyanide, constitution of (MÜLLER and DIERFENHALEN), A., i, 721.
- Lead, estimation of (SACHER), A., ii, 75, 153.
- estimation of small quantities of, in alloys of antimony, copper and tin (MANN), A., ii, 898.
- approximate estimation of small quantities of (HARGGURT), T., 841; P., 82.
- colorimetric estimation of, in potable water (SCHERINGA), A., ii, 1112.
- volumetric estimation of (RUFF), A., ii, 243.
- electro-analytical determination of, as peroxide (SAND), A., ii, 456.
- Lead chamber process, theory of (MANCHOT), A., ii, 1055.
- Leaves, green, toxicity of salts towards (MAQUENNE and DEMOUSSEY), A., ii, 801.

- Lecithin**, biological importance of (GLIEM), A., ii, 58.
 content in bone marrow (BOLLE), A., ii, 429.
 free and combined, in germinating seeds (BERNARDINI and CHIARULLI), A., ii, 991.
 influence of, on metabolism (YOSHIMOTO), A., ii, 321.
 effect of, on the digestion of fat (USUKI), A., ii, 972.
 estimation of (NERKING), A., ii, 162.
 in soya-oil (RIEDEL), A., ii, 662.
Leothins, bactericidal properties of (RENSHAW and ATKINS), A., ii, 332.
 non-existence of, in the yolk of eggs (BARBIERI), A., i, 704.
Lemon-grass oils (SCHIMMEL & Co.), A., i, 323.
Lemon juice, estimation of citric acid in (SPICA), A., ii, 1120.
Lemon oil, constituents of (GILDEMEISTER and MÜLLER), A., i, 185.
Lens, crystalline, chemico-physical investigations of the (QUAGLIARIELLO), A., ii, 56; (BOTTAZZI and SCALINO), A., ii, 56, 143, 975.
 β -Leonecopal resin (WILLNER), A., i, 499.
Leonecopalic acid (WILLNER), A., i, 498.
Leonecopalinic acid (WILLNER), A., i, 499.
Leonecopalolic acid (WILLNER), A., i, 498.
Leptandra, constituents of (POWER and ROGERSON), T., 1944; P., 218.
Lencine, degradation of, in the liver (SACHS), A., ii, 790.
***L*-Leucine**, derivatives of (ABDERHALDEN and WEBER), A., i, 719.
***iso*Leucine**, derivatives of (ABDERHALDEN and SCHULER), A., i, 304; (ABDERHALDEN and HIRSCH), A., i, 730.
 degradation of, in the liver (WIEHL), A., ii, 789.
Leucocytes, composition and properties of (MANCINI), A., ii, 726.
 a diastatic enzyme in (HABERLANDT), A., ii, 515.
Leucomethylone blue, and its sodium salt, and nitro- (LANDAUER and WEIL), A., i, 202.
Leuco-exindirubin (2:1'-dihydroxy-1:2'-dicoumarone) (FRIES and PRAFFENBORFF), A., i, 186.
Leucepeilin (FRÄNKEL and ELIAS), A., i, 906.
Leucoprotease (BRADLEY), A., i, 795.
Leucoquinine (COMANUCCI), A., i, 582.
***d,l*-Leucotannin**, hexa-acetyl, and strychnine salt of the *l*-compound- (NIERENSTEIN), A., i, 265.
***L*-Leucyl-*L*-aspartic acid** (FISCHER and FIEDLER), A., i, 657.
***L*-Leucylglycyl-*L*-aspartic acid** (FISCHER and FIEDLER), A., i, 657.
***L*-Leucylglycyl-leucine** (ABDERHALDEN and WEBER), A., i, 719.
***L*-Leucylglycyl-*d*-isoleucine** (ABDERHALDEN and SCHULER), A., i, 305.
***L*-Leucylglycyl-*L*-leucylglycyl-*L*-leucine** (ABDERHALDEN and WEBER), A., i, 719.
***L*-Leucyl-*L*-isoleucine** (ABDERHALDEN and SCHULER), A., i, 305.
***L*-Leucyl-*d*-isoleucine anhydride** (ABDERHALDEN and HIRSCH), A., i, 720.
***d*-Leucyl-*L*-tryptophan** (FISCHER), A., i, 22.
 behaviour of, towards autolytic ferments (FISCHER), A., i, 599.
Lichen derivatives, rotatory power of (SALKOWSKI), A., i, 851.
Light. See under Photochemistry.
Ligia oceanica, colour change in (TAIT), A., ii, 731.
Lignin, formation of acetic and formic acids by hydrolysis of substances containing (CROSS), A., i, 457.
Lime. See Calcium oxide.
Lime oil (HAENSEL), A., i, 401.
Limonene, oxides of (PRIESCHAEFF), A., i, 86.
 α - and β -Limonenehydroxylamineoximes, and their hydrochlorides (GEMMAN), A., i, 685.
Limulus, blood-cells of, influence of changes in chemical and physical conditions on the (LOEB), A., ii, 420.
Limulus polyphemus, hemocyanin of (ALBERG and CLARK), A., i, 647.
Linalool, action of hydrochloric acid on (DUFONT and LABAUNE), A., i, 184.
 oxides of (PRIESCHAEFF), A., i, 86.
Linalyl chloride (DUFONT and LABAUNE), A., i, 184.
Linaria striata, a cyanogenetic glucoside in (BOUCHÉLOT), A., ii, 63.
Linase (ARMSTRONG and EVANS), P., 355.
Linolenic acid (ERDMANN and BEDFORD), A., i, 810.
 constitution of (GOLDSOBER), A., i, 216.
***iso*Linolenic acid**, constitution of (GOLDSOBER), A., i, 216.
Linseed oil, composition of (ERDMANN and BEDFORD), A., i, 810.
Lipase (BRADLEY), A., ii, 727.
 gastric, in human embryo (BRADLEY and KOPPEL), A., ii, 122.
 pancreatic, action of haemolytic agents and cholesterol on (ROSEBERG and SHAW-MACKENZIE), A., i, 517.

- Lipase, pancreatic, action of serum on and separation of, from its co-enzyme (ROSENHEIM and SHAW-MACKENZIE; ROSENHEIM), A., ii, 517.
- reactions of (BRADLEY), A., i, 800.
- Lipids (FRÄNKEL and LINNERT), A., i, 295, 600; ii, 729; (FRÄNKEL and OFFER), A., i, 600; (FRÄNKEL and ELIAS), A., i, 906; (FRÄNKEL and DIMITZ), A., ii, 1086.
- of the brain (ROSENHEIM and TEBB), A., ii, 1085.
- of the spinal column (SIGNORELLI), A., ii, 1087.
- iron-containing, in the spleen (BUROW), A., ii, 630.
- hemolysis by (LIEFMANN and COHN), A., ii, 726.
- relation of, to hemolysis (MEYERSTEIN), A., ii, 514.
- dependence of plant respiration on the presence of (PALLADIN and STANEWITSCH), A., ii, 799.
- influence of, on the autolysis of wheat seedlings (KORSAKOFF), A., ii, 990.
- action of chloroform on (CALEGAREANO), A., ii, 1049.
- Lipo-peptides, synthesis and cleavage of (BONDI and EISLER), A., i, 157.
- Lipo-proteins, and their significance in fatty degeneration of cells (BONDI and EISLER), A., i, 157.
- quids, apparatus for measuring known quantities of (HUNIG and VAN'T KRUYE), A., ii, 995.
- compressibility coefficients of (SUCHODSKI), A., ii, 823.
- properties of, at the boiling point (TYRER), A., ii, 827.
- spraying of, ionisation by the (BLOCK), A., ii, 480.
- absorption of, by porous substances (RUSSENBERGER), A., ii, 189.
- extraction of, with Soxhlet's apparatus (SAIKI), A., ii, 117.
- and solids, thermal properties of (LUSSANA), A., ii, 589.
- associated (KURBATOFF and ELISÉEFF), A., ii, 102.
- anisotropic (ROTASKEI), A., ii, 695; (FRIEDEL and GRANDJEAN), A., ii, 809, 1018.
- combustible, estimation of carbon, hydrogen and nitrogen in (BERL), A., ii, 242.
- organic, purification of, by fractional distillation (TIMMERMANS), A., i, 533.
- method of drying (JACKSON and FISKE), A., ii, 1110.
- Liquid mixtures, Pulfrich's ratio between volume contraction and refractive power of (VAN AUBREL), A., ii, 169.
- Lithium, atomic weight of (RICHARDS and WILLARD), A., ii, 292.
- ultra-red line spectrum of (PASCHEN), A., ii, 1014.
- behaviour of, towards sodium, potassium, tin, cadmium and magnesium (MASING and TAMMANN), A., ii, 610.
- action of, on organic halides (SPENCER and PRICE), T., 385; P., 26.
- Lithium alloys with mercury, electrochemical investigation of (RICHARDS and GARROD-THOMAS), A., ii, 384.
- Lithium salts, behaviour of plants towards (RAVENNA and ZAMORANI), A., ii, 235.
- Lithium nitrate, action of, on insoluble carbonates (OLCHNER DE CONINCK), A., ii, 847.
- phosphomolybdates (EPHRAIM and BRAND), A., ii, 207.
- sulphate, sulphuric acid and water at 30°, the system (VAN DORP), A., ii, 608.
- Lithium, estimation of, in waters (LECCO), A., ii, 463.
- Litmus, solubility of, in alcohol (SCHRITZ), A., i, 866.
- Liver, functions of the (NEUBAUER and FISCHER), A., ii, 790.
- hemolysis in the (FINDLAY), A., ii, 788.
- reducing properties of (ROSENTHALER), A., ii, 1089.
- depression of the ammonia-destroying power of (CARLSON and JACOBSON), A., ii, 324.
- fatty acid metabolism in the (MOTTRAM), A., ii, 525.
- formation of acetoacetic acid in the (EMDEN and WIRTH; GRIEBACH), A., ii, 789.
- enzymes of the, decomposition of acetoacetic acid by (WAKEMAN and DAKIN), A., ii, 977.
- cholesterol esters and an enzyme capable of splitting them in (KONDO), A., ii, 791.
- iron-content of, after feeding on ferratin (IMABUCHI), A., ii, 324.
- pigments from invertebrates (PALADINO), A., ii, 977.
- formation of hydroxy-fatty acids during autolysis of the (KONDO), A., ii, 791.
- degradation of leucine in the (SACHS), A., ii, 790.
- degradation of isoleucine in the (WIRTH), A., ii, 789.

- Liver**, behaviour of β -*p*-hydroxyphenyl- α -lactic and *p*-hydroxyphenylpyruvic acids in the (SCHMITZ), A., ii, 984.
secretion by the, of an anticoagulating substance (DEVON), A., ii, 427.
artificially perfused, tyrosine katabolism in the (NEUBAUER and GROSS), A., ii, 790.
of the dog, lactic acid in the antolysed (SAIKI), A., ii, 142.
tortoise's, formation of glycogen in, with pancreatic diabetes (NISHI), A., ii, 227.
estimation of glycogen in (PFLÜGER), A., ii, 225.
 β -Loangocopal resin (WILLNER), A., i, 498.
 α - and β -Loangocopalic acid (WILLNER), A., i, 498.
Loangocopalinic acid (WILLNER), A., i, 498.
Loangocopallic acid (WILLNER), A., i, 498.
Ludwigite from Montana (SCHALLER), A., ii, 878.
Lujaurites from Pilsaidsberg (BROUWER), A., ii, 48.
Luminescence (KOWALSKI), A., ii, 371.
phenomena in certain organic compounds (POCHETTINO), A., ii, 5.
Lumaria biennis, alkaloid in the seeds of (HAIRS), A., ii, 234.
Lungs, exhalation of drugs by (CUSHNY), A., ii, 525.
Lupanine, hydroxy- (BECKEL), A., i, 694.
Lupose (SCHULZE), A., i, 610.
Luteol as an indicator (DE JAGER), A., ii, 746.
Lutidines. See Dimethylpyridines.
Lymph, electrical conductivity of (LUCK-HARDT), A., ii, 226.
fractional coagulation of (LUSKY), A., ii, 226.
flow of, effect of injection of colloids and crystalloids on the (PROLIESZ), A., ii, 437.

M.

- Mageuta tetraperchlorate** (HOFMANN, ROTH, HÖBOLD, and METZLER), A., i, 819.
Magma, basaltic, crystallisation of (FENNER), A., ii, 313.
Magnesium content in the human organs (MAGNUS-LEVY), A., ii, 426.
duration of the spectral rays emitted by the vapour of, in the electric spark (HEMSALECH), A., ii, 1014.
Magnesium, origin of the use of, in organic syntheses (BARBER), A., i, 308.
action of, on the vapours of organic compounds (KEISER and McMASTER), A., i, 213.
application of, in organic syntheses (GRIGNARD), A., i, 466.
behaviour of lithium towards (MASING and TAMMANN), A., ii, 610.
and barium, antagonistic action of (JOSEPH and MELTZER), A., ii, 228.
Magnesium alloys with gold (URAZOFF), A., ii, 43; (URAZOFF and VOGEL), A., ii, 872.
with zinc and cadmium (BRUSI, SANDONNINI, and QUARONCE), A., ii, 954.
Magnesium salts, alleged anæsthetic properties of (GUTHRIE and REAN), A., ii, 793.
Magnesium, carbides of (NOVÁK), A., ii, 778.
carbonate, hydrated, prepared by Moressée (CESARO), A., ii, 613.
chloride, the reversible action of oxygen on (HIRSCHKIND), A., ii, 613.
chlorides, basic (ROBINSON and WAGGAMAN), A., ii, 37.
ammonium phosphate (BUEE), A., ii, 804.
ammonium sulphate, solubility of (LOTHIAN), A., ii, 504.
oxytrithiophosphate and dioxydiethenophosphate (EPHRAIM and MAJLER), A., ii, 206.
Magnesium organic compounds, reaction of unsaturated compounds with (KOHLEK and BURNLEY), A., i, 391; (REYNOLDS), A., i, 857.
scission of phenolic ethers by (GARNARD), A., i, 669.
action of acetic anhydride and its homologues on (FOURNIER), A., i, 652.
action of, on aldehydes (BUSCH and FLEISCHMANN), A., i, 222.
action of, on anilides and their chlorides (BUSCH and FLEISCHMANN), A., i, 728.
action of, on boron trichloride, sulphur chloride, and the esters of sulphurous acid (STRECKER), A., i, 532.
action of, on haloal derivatives of sulphur (FERRARIO and VIGAT), A., i, 604.
action of, on thiouyl chloride (STRECKER, GRIGNARD and ZERST), A., i, 532.
action of, on tiglic aldehyde (AMMANN), A., i, 454.

Magnesium organic compounds:—

Magnesium *tert.*-butyl chloride, action of, on ethyl oxalate (EGOROVA), A., i, 90.

cyclohexyl chloride, action of sulphur and selenium on (MAILHE and MURAT), A., i, 374.

pyrryl iodide, synthesis of pyrrole derivatives by means of (ODDO), A., i, 426.

triphenylmethyl chloride (SCHMIDLIN), A., i, 368.

Magnesium and calcium, separation of (McCRUDDEN), A., ii, 243; (MURMANN), A., ii, 897.

estimation of, in presence of iron (SCHMIDT), A., ii, 899.

estimation of, in soils, in the presence of manganese (DESORMAY), A., ii, 243.

iodometric estimation of, in the triple phosphate (BRANDIS), A., ii, 345.

Magnetic double refraction. See under Photochemistry.

field, use of, for the determination of constitution in organic chemistry (PASCAL), A., ii, 100, 179.

properties of alloys as a function of the composition and the temperature (HONDA), A., ii, 686.

rotation. See under Photochemistry.

susceptibilities of chromophoric groups (PASCAL), A., ii, 580.

of platinum metals and monoclinic crystals (FINKEL), A., ii, 179.

of solids (PASCAL), A., ii, 483.

Magnetism of solutions (DRAPIER), A., ii, 99.

Maize, effect of nutrition with (BAGLIONI), A., ii, 625.

Maize blight. See *Ustilago Maydis Tulazae*.

Malaria, prophylaxis in (GRAZIANI), A., ii, 982.

Maleic acid, methyl ester and anhydride of, action of Grignard reagents on (FURDI and ARUP), T., 1537; P., 199.

characteristic reaction of (LUTZ), A., i, 879.

Maleic acid, bromo-, pyridine, and quinoline salts of (PFEIFFER, LANGENBURG, and BIRENOWER), A., i, 878.

di-bromo-, methyl hydrogen ester (DIELS and REINBECK), A., i, 360.

Maleic anhydride, rate of hydration of (RIVETT and SIDGWICK), T., 1677; P., 200.

di-iodo- (DIELS and REINBECK), A., i, 360.

Maleimide-*p*-phenylacetic acid, hydroxy-, ethyl ester (WIELICENUS and PENNDORF), A., i, 560.

Malic acid, rotatory power of, in the presence of ammonium molybdate and sodium phosphate (MADERNA), A., ii, 915.

Malonamidehydrazide, preparation of (BÜLOW and BOZENHARDT), A., i, 233.

Malonamidehydrazonoacetoacetic acid, ethyl ester (BÜLOW and BOZENHARDT), A., i, 233.

Malonanilic acid, preparation of (CHATTAWAY and OLMSTED), T., 939.

p-bromo-, 2,4-*di*-bromo-, *p*-chloro-, 2,4-*di*-chloro-, and 2,4,6-*tri*-chloro-, 2,4,6-*tri*-bromo-, and their ethyl esters (CHATTAWAY and MASON), T., 341.

Malonanilide, *pp*-*di*-bromo-, 2,4:2':4'-*tetra*-bromo-, 2,4:6:2':4':6'-*hexa*-bromo-, *pp*-*di*-chloro-, 2,4:2':4'-*tetra*-chloro-, and 2,4:6:2':4':6'-*hexa*-chloro- (CHATTAWAY and MASON), T., 340.

Malonic acid, estimation of, by potassium permanganate (CAMERON and McEWAN), P., 144.

Malonic acid, ethyl ester, replacement of alkyl groups in (KOMENOS), A., i, 541.

action of aromatic amines on (CHATTAWAY and OLMSTED), T., 938; P., 69.

Malono-*o*- and *p*-toluidic acids, preparation of (CHATTAWAY and OLMSTED), T., 940.

1:1-Malonylbis-4-benzeneazo-3-methyl-5-pyrazolone (BÜLOW and BOZENHARDT), A., i, 205.

Malonylbishydrazonoacetoacetic acid, ethylester, decomposition products and bisazo-compounds of (BÜLOW and BOZENHARDT), A., i, 103, 205.

oximino-, preparation and decomposition of (BÜLOW and BOZENHARDT), A., i, 233.

Malonylbishydrazonobenzeneazoacetoacetic acid, ethyl ester (BÜLOW and BOZENHARDT), A., i, 205.

Malonylbishydrazono-methyl-, ethyl-, isobutyl-, and benzyl-, acetoacetic acid, ethyl esters (BÜLOW and BOZENHARDT), A., i, 103.

Malonylbishydrazonoxalacetic acid, ethyl ester (BÜLOW and BOZENHARDT), A., i, 103.

Malonylbishydrazonotoluene-*p*-azoxoacetoacetic acid, ethyl ester (BÜLOW and BOZENHARDT), A., i, 205.

Malonyldiguamide. See 4:6-Diketo-2-guanidinopyrimidine.

cycloMalonylhydrazide (BÜLOW and BOZENHARDT), A., i, 103.

- Malt**, amylase from (CHRSZCZ), A., ii, 994.
 invertase from (VANDELDE), A., i, 798.
 infusions, antidiastase in (VANDELDE), A., ii, 645.
Maltol, and its derivatives (BACKE), A., i, 544.
Maltose, derivatives of (FISCHER and FISCHER), A., i, 716.
Maltose, hepta-acetyl (FISCHER and FISCHER), A., i, 717.
Mandellic acid, 5-bromo-2-amino-, and 5-chloro-2-nitro-, and methyl ester of the latter (HELLER and FRANTZ), A., i, 849.
 β -hydroxy, and its calcium and cinchonine salts, and its presence in urine in yellow atrophy of the liver (ELLINGER and KOTAKE), A., i, 385.
Mandelic acid, methyl ester, optically active glycols from (MCKENZIE and WEEN), T., 473; P., 54.
Mandelonitrile, 5-bromo-2-nitro-, 5-bromo-2-nitroso-, and 5-chloro-2-nitro- (HELLER and FRANTZ), A., i, 848.
Manganese, occurrence of, in soil and its effect on grass (GUTHRIE and COHEN), A., ii, 444.
 in fresh-water mussels (BRADLEY), A., ii, 731.
 in animal tissues (BRADLEY), A., ii, 979.
 band spectrum of (CASARETTO), A., ii, 671.
 magnetic properties of (WEISS and ONNES), A., ii, 388.
 anodic behaviour of (KUESSNER), A., ii, 927.
Manganese alloys, magnetisable (HEULEN), A., ii, 179.
 with copper, analysis of (AZZARILLO), A., ii, 754.
 with iron and carbon (ARNOLD and READ), A., ii, 1071.
Manganese salts of hydroxy-acids (TAMM), A., ii, 859.
Manganese oxides, heat of combination of, with sodium oxide (MIXTER), A., ii, 823.
 fusion of, with potassium hydroxide (ASKENASY and KLONOWSKI), A., ii, 297.
 influence of atmospheric oxygen on the oxidation of oxalic acid by (SCHRÖDER), A., ii, 899.
 dioxide, colloidal (DEISS), A., ii, 213.
Manganates, thermal formation of, and molecular weights of (SACKUR), A., ii, 214, 215.
- Manganese**:-
Manganates, electrolytic conversion of, into permanganates (BRAND and RABERÖTTOM), A., ii, 958.
Permanganic acid, and its salts, spontaneous decomposition of (SKRAHAL), A., ii, 855.
Permanganates, influence of dilution on the colour and absorption spectra of (PURVIS), A., ii, 8.
 titration of (BRAY), A., ii, 1001.
Manganomanganates of the alkali metals (AUGER), A., ii, 298.
Manganomanganic thallous fluorite (EPHRAIM and HEYMAN), A., ii, 37.
Manganic fluorides, preparation of (MÜLLER and KOPPE), A., ii, 957.
Manganous calcium bromide (EPHRAIM and MODEL), A., ii, 855.
Manganese organic compounds:-
Manganese molybdenum cyanide (ROSENHEIM, GAEFUNKEL, and KOHN), A., i, 102.
Manganese, detection of, in foods (DUMITRESCU and NICHOLAU), A., ii, 1001.
 detection and estimation of, in wines (DUMITRESCU and NICHOLAU), A., ii, 1114.
 estimation of (FISCHER), A., ii, 76; (DEISS), A., ii, 851.
 estimation of, in potable water (RODENBURG), A., ii, 1000.
 volumetric estimation of (DONATI), A., ii, 550; (KARAOGLANOFF), A., ii, 754; (METZGER and McCrackan), A., ii, 1000.
 volumetric estimation of, in manganese ores (KRISHNAYYA), P., 129.
 titration of, in the presence of fluorides (MÜLLER and KOPPE), A., ii, 957.
 and chromium, separation of (FAIRLO), A., ii, 76.
Manganese-boron, Goldschmidt's, behaviour of, on heating in chlorine and hydrogen sulphide (HOFFMANN), A., ii, 508, 959.
Manganese minerals, from Veitsh, Syria (HOFMANN and SLAVIK), A., ii, 314.
Mannans, nutritive value of (SWARTZ), A., ii, 727.
Mannide diacetate (BLOOR), A., i, 530.
Mannitol hexaphosphate (CONTARD), A., i, 610.
Mannitols, partial transformation of alimentary fatty matter into, by peptic and pancreatic digestion (GAUTHERIE), A., ii, 140.
Mannochloraloses, and its acetyl and benzoyl derivatives (HANRIOT), A., i, 95.

- Mannoseanilide** (IRVING and McNICOLL), T., 1453.
- Manure**, new, "Palmaer phosphate" (v. FEILITZEN), A., ii, 538.
- catalytic, use of boron as (AGULHON), A., ii, 236.
- Manorial experiments**, mineralogical significance of (SAMOILOFF), A., ii, 534.
- with carbon dioxide (MITSCHERLICH), A., ii, 236.
- action of zinc in (EHRNEBERG), A., ii, 236.
- on peat soil with "Palmaer phosphate" (v. FEILITZEN), A., ii, 538.
- Margarine**, estimation of, in butter (RAFFO and FORESTI), A., ii, 360.
- Massage**, action of, on protein metabolism (RANCKEN), A., ii, 521.
- Matico oils**, composition of (THOMS), A., i, 122.
- Matairesinol** (EASTFIELD and BEE), T., 1028; P., 7.
- Matairesinolic acid**, and its calcium salt (EASTFIELD and BEE), T., 1031; P., 7.
- Matairesinoldisulphenic acid** (EASTFIELD and BEE), T., 1030; P., 7.
- Matter**, history of the orientation theory of (v. WEIMARN), A., ii, 1048.
- equation of continuity of the liquid and gaseous states of (KLEEMAN), A., ii, 932.
- Meat**, detection of benzoic acid in (FISCHER and GRUENERT), A., ii, 1121.
- determination of ammoniacal nitrogen in (PENNINGTON and GREENLEE), A., ii, 449.
- estimation of phosphorus in (TROWBRIDGE), A., ii, 546.
- estimation of potassium nitrate in (PAAL and GÄNGHOFER), A., ii, 453.
- Meat extract**, occurrence of inactive lactic acid in a (SALKOWSKI), A., ii, 55.
- Meat extracts**, separation of creatinine from (MICKO), A., ii, 557.
- Malamin**, effect of alkali on (GORTNER), A., i, 760.
- Malanins**, formation of, by diastatic oxidation (AGULHON), A., i, 449.
- Melanuria** (EPPINGER), A., ii, 1092.
- Maliatin** (BRIDEL), A., i, 692.
- Melophanic acid** (benzene-1:2:3:4-tetracarboxylic acid), constitution and methyl ester of (BAMFORD and SIMONSEN), T., 1908; P., 206.
- Melting point apparatus** (STOLTZENBERG), A., ii, 17; (MATTON), A., ii, 388; (WEYL), A., ii, 483.
- Melting point apparatus**, use of, as a low temperature bath (STOLTZENBERG), A., ii, 267.
- determination of, at low temperatures (STOLTZENBERG), A., ii, 182.
- Melting-point curve**, influence of critical solution point on the shape of the (FLASCHNER and RANKIN), A., i, 255.
- Melting point curves** of aromatic diazoamines (SMITH and WATTS), T., 562; P., 45.
- Membranes**, action of (BRCHOLD and ZIEGLER), A., ii, 191.
- Memorial lecture**, Thomeen (TORPE), T., 161.
- Menispermum Canadense*, fruit of (NEIDIG), A., ii, 801.
- Mentha arvensis*, oil from (ROURE-BERTRAND FILS, DUPONT, and LABAUNE), A., i, 756.
- Mentha sylvestris* oil (SCHIMMEL & Co.), A., i, 329.
- dl-Δ^{4,8,9}-m-Menthadiene* (PERKIN), T., 2147.
- dl-, d-, and l-Δ^{4,8,9}-m-Menthadiene* (PERKIN), T., 2139, 2142.
- Δ^{3,8,9}-p-Menthadiene*, new method of preparation of (PERKIN and WALLACH), T., 1427; P., 194.
- Menthan-2:5-diol** (HENDERSON and SUTHERLAND), T., 1618; P., 203.
- Menthan-4:8-diol** (WALLACH), A., i, 569.
- Menthenes**, formation of, from pulegona (AUWERS), A., i, 122.
- Δ³-m-Menthenol(8)*, phenylurethane of (LUFF and PERKIN), T., 2153.
- dl-Δ⁴-m-Menthenol(8)* (PERKIN), T., 2147.
- dl-, d-, and l-Δ³-m-Menthenol(8)* (PERKIN), T., 2139, 2141, 2143.
- Δ³-p-Menthenol(8)*, new method of preparation of, and its phenylurethane (PERKIN and WALLACH), T., 1427; P., 194.
- Δ¹-Menthenone*, from Japanese pepper mint oil, and its derivatives (SCHIMMEL & Co.), A., i, 757.
- l-Menthoethylheptanonolide* (GILDEMEISTER and KÖHLER), A., i, 181.
- Menthol**, rotation of (GROSSMANN), A., ii, 563.
- tertiary, a new, and its derivatives (BÉHAL), A., i, 572.
- d-Menthol*, derivatives of (TSCHUGAEFF), A., i, 862.
- d-iso-Mentholcarboxylic acid* (GARDNER, PERKIN, and WATSON), T., 1771.
- Menthone**, action of magnesium and allyl bromide on (RYSCHENKO), A., i, 181.

- Menthencarboxylic acid** (GARDNER, PERKIN, and WATSON), P., 137.
- d-isoMenthencarboxylic acid** (GARDNER, PERKIN, and WATSON), T., 1770.
- d-isoMenthenedicarboxylic acid** (GARDNER, PERKIN, and WATSON), T., 1772.
- syn- and anti-Menthonylbenshydroximic acid** (CUSMANO), A., i, 50.
- Monthyldiethylbensamidine, and its hydrochloride, hydriodide, and platinichloride** (COHEN and MARSHALL), T., 333.
- Monthyloethylbensamidine, and its hydrochloride, hydriodide, and platinichloride** (COHEN and MARSHALL), T., 333.
- Menthylglycuronic acid, new method of obtaining** (NEUBERG and LACHMANN), A., i, 325.
- Monthylmaltocide, and its barium salt and hepta-acetyl derivative** (FISCHER and FISCHER), A., i, 717.
- Mercury, atomic weight of** (EASLEY), A., ii, 957.
- ionisation produced by splashing of** (LONSDALE), A., ii, 922.
- spectrum of** (PASCHEN), A., ii, 3; (ROYDS), A., ii, 87.
- series spectrum of** (MILNER), A., ii, 914.
- ultra-red line spectrum of** (PASCHEN), A., ii, 1014.
- determination of the vapour pressures of** (SMITH and MENZIES), A., ii, 1087.
- purification of** (MOORE), A., ii, 712.
- equilibrium in the ternary system, lead, cadmium, and** (JÄNCKE), A., ii, 699.
- and hirudin** (PRENSAK), A., ii, 229.
- preparation of pyrimidine derivatives containing** (FÄRGENFÄRRIKEN VORM. F. BAYER & CO.), A., i, 804.
- and mercuric oxide, action of thionyl and sulphuryl chlorides on** (NORTH), A., ii, 296.
- Mercury alloys (amalgams), interaction of mixed salt solutions and** (SMITH), A., ii, 401.
- with alkali and alkaline-earth metals** (SMITH and BENNETT), A., ii, 500.
- with potassium, photo-electric effect of** (POHL and PRINGSHEIM), A., ii, 422.
- with sodium, action of, on methylene ethers** (SALWAY), T., 2413; P., 293.
- with sodium, assay of, with the "decomposition flask"** (BERL and JURRISEN), A., ii, 242.
- silver** (JONES), T., 336; P., 47.
- Mercury alloys (amalgams), with thallium, indium, and tin, electrochemical investigation of** (RICHARDS and WILSON), A., ii, 384.
- with zinc, cadmium, lead, copper, and lithium** (RICHARDS and GARDNER-THOMAS), A., ii, 384.
- with zinc** (COHEN and INOUE), A., ii, 37.
- E.M.F. of** (CHENSHAW), A., ii, 258.
- Mercury compounds, influence of, on metabolism** (IZAR), A., ii, 53.
- Mercury salts, additive compounds of, and aromatic bases** (STARONKA), A., i, 876.
- the aluminium reaction of** (HURT), A., ii, 805.
- action of, on autolysis** (TRUFFET), A., ii, 142.
- halides** (VAN NEST), A., ii, 295.
- the double nitrites of, and the bases of the tetra-alkylammonium series** (RIV), P., 172.
- oxides, electromotive properties of** (ALLMAND), A., ii, 572.
- Mercurous chloride, vapour pressure of** (SMITH), A., ii, 273.
- the system: mercuric chloride and** (JONKER), A., ii, 127.
- action of ammonia on** (SAHA and CHOUDHURI), A., ii, 712.
- Mercuric bromide, ammonia compounds of** (WIDMAN), A., ii, 802.
- Mercuric halides, vapour pressures and molecular volumes of** (FIDEAUX), T., 2032; P., 207.
- bromide and chloride, equilibrium of, with potassium hydroxide,** (HERZ), A., ii, 945.
- chloride, preparation of, by the wet process** (RUPP and KLEE), A., ii, 615.
- ultramicroscopic observations of the hydrolysis of** (FISCHER and BRIEGER), A., ii, 857.
- the system: mercurous chloride and** (JONKER), A., ii, 127.
- equilibrium in the system, pyridine, and** (McBRIDE), A., ii, 401.
- action of, on aluminium** (KORABREST), A., ii, 506.
- detection of, in compressed gas-cotton** (JANNOPoulos), A., ii, 444.
- titration of** (RUPP), A., ii, 456.
- barium chloride** (SCHREINMAKERS), A., ii, 490.
- barium, calcium, and strontium nitrites** (RIV), T., 326; P., 7.
- oxide, action of thionyl and sulphuryl chlorides on** (NORTH), A., ii, 296.

Mercury:—

Dimercurammonium bromide (GAUDICHON), A., ii, 296.
nitrite, decomposition of, by heat (RAY and GHOSH), T., 323; P., 6.

Mercury organic compounds:—

Mercury chloro- and bromo-acetylides (HOFMANN and KIRMREUTHER), A., i, 16.

Mercurycarboxylic acids, hydroxy-, preparation of soluble compounds from the anhydrides of (SCHOMMLER and SCHRAUTH), A., i, 459.

fulminate (SOLONINA), A., i, 464.

Mercuriacetic acid, trichloro-, and trihydroxy- (HOFMANN and KIRMREUTHER), A., i, 17.

Mercuricampher compounds, action of halogens on (MARSH), T., 2410; P., 297.

α -Mercuri- β -hydroxy- β -phenylpropionic acid, inner salt of (BILMANN and BJERRUM), A., i, 347.

Mercuri- β -methoxy- β -phenylpropionic acid, α -hydroxy-, anhydride of (SCHRAUTH, SCHOELLER, and STRUENEE), A., i, 347.

Mercury, detection of, in urine (BECKER; GLASER and ISENBERG), A., ii, 75.

detection of, by the "aluminium reaction" (REICHARD), A., i, 655.

toxicological detection of (LECCO), A., ii, 456.

micro-chemical estimation of (RAASCHOU), A., ii, 350.

estimation of, in urine and faeces (SIEBERT), A., ii, 656.

volumetric estimation of, by means of ammonia (BRESSANIN), A., ii, 1000.

volumetric estimation of, in galenical preparations (GRÜTER), A., ii, 656.

and silver, volumetric separation of (RIPP and LEHMANN), A., ii, 350.

estimation of, with gold cathode (PERKIN), A., ii, 75.

Mercury minerals from Terlingua, Texas (HILKEBRAND and SCHALLER), A., ii, 106.

Mercuridine, absorption spectrum of (FURY), T., 1552.

Mesitylcarbinol, phenylurethane of (CARRE), A., i, 620.

Mesityleneazoglutaconic acid, ethyl ester, mesitylhydrazone (HENRICH, LEICHENBURG, NÄCHTIGALL, THOMAS, and BAUM), A., i, 901.

Mitylenic acid, 4-amino-, ethyl ester (WHEELER and HOFFMAN), A., i, 666.

Mityl oxide (methyl isobutyl ketone, α -propylideneacetone), aminopyrrolone derivatives from (KOHN and DM), A., i, 316.

Mesityl oxide, semicarbazide-semicarbazone hydrochloride (RUPE and KESSLER), A., i, 15.

dibromide semicarbazone (RUPE and KESSLER), A., i, 93.

S-Mesitylphenazothionium, dinitro-, hydroxido (BARNETT and SMILES), T., 371.

Mesolite from the Faroe Islands (GÖRGEY), A., ii, 312.

from the Radathal, Harz (FROMME), A., ii, 314.

Mesothorium, chemistry of (SODDY), P., 338.

Mesoaxaldehyde, *p*-nitrophenylhydrazones (HARRIES and TÜRK), A., i, 608.

Mesoaxalic acid, ethyl ester, condensation of phenyliso-oxazolone with (MEYER), A., i, 593.

Mesoaxalylphenylhydrazonedihydrazide (BÜLOW and BOZENHARDT), A., i, 205.

Metabolic disturbance after extirpation of the suprarenal glands (SCHWARZ), A., ii, 978.

Metabolism, experiments on, as statistical problems (RIETZ and MITCHELL), A., ii, 1082.

influence of alcohol on (MENDEL and HILMICH), A., ii, 223.

effect of castration on (McCRUDEN), A., ii, 321.

in relation to digestion (DAHM), A., ii, 1083.

in Addison's disease (BEUTENMÜLLER and STOLZENBERG), A., ii, 982.

in protracted inanition (GRAFF), A., ii, 422.

influence of lecithin on (YOSHIMOTO), A., ii, 321.

influence of mercury compounds on (IZAK), A., ii, 53.

after-effect of increased muscular work on (JAQUET), A., ii, 519.

effect of water drinking with meals on (FOWLER and HAWK), A., ii, 625.

the value of protein cleavage products in (ANDERHALDEN and FRANK), A., ii, 322; (ANDERHALDEN and GLAMER; ANDERHALDEN and MANOLI), A., ii, 521.

of fatty acids in the liver (MOTTRAM), A., ii, 525.

of calcium, magnesium, and phosphorus (KOCHMANN), A., ii, 786.

of carbohydrates (WACKER), A., ii, 806.

of oxalic acid (TOMASZEWSKI), A., ii, 425.

of phosphorus (ROGOZINSKI), A., ii, 972.

- Metabolism of sodium chloride in man** (TUTTUR; v. HOESSLIN), A., ii, 424.
- of uric acid in dogs (ACKROYD), A., ii, 977.
- cardiac, of alcohol (HAMILL), A., ii, 921.
- carbohydrate, in *Carcinus maenas* (v. SCHÖNBORN), A., ii, 1083.
- gaseous, in anoxihæmia (LESSER), A., ii, 429.
- of various organs (COHNHEIM; COHNHEIM and PLETNEFF), A., ii, 1079.
- effect of carbohydrate food on (MÜLLER), A., ii, 1083.
- of sea animals, influence of oxygen pressure on (HENZE), A., ii, 785.
- of the dog's heart during vagus inhibition (WOLFSOHN and KETRON), A., ii, 222.
- of infants (SCHLOSSMANN and MURCHHAUSER), A., ii, 724.
- of the small intestine (BRODIE and VOGT; BRODIE, CULLIS, and HALLIBURTON), A., ii, 518.
- heart (BORDE), A., ii, 976.
- nitrogen, relation between, and uric acid excretion (BIERNACKI), A., ii, 423.
- in pregnant dogs (MURLIN), A., ii, 729, 1082.
- influence of the removal of the small intestine on (CARREL, MEYER, and LEVENE), A., ii, 323.
- influence of excision of the stomach on (CARREL, MEYER, and LEVENE), A., ii, 974.
- of rabbits, influence of nucleic, and uric acids and allantoin on the (SCHITTENHELM and SEISSER), A., ii, 423.
- of nitrogen and phosphorus, relation between the (GRUND), A., ii, 624.
- nuclein, in the pig (SCHITTENHELM), A., ii, 626.
- oxygen, of the blood (KROGH), A., ii, 512.
- phosphorus, in man (HOLST; HEUBNER), A., ii, 519.
- protein, action of massage on (RANCKEN), A., ii, 521.
- influence of carbohydrate and fat on (CATHCART and TAYLOR), A., ii, 1084.
- influence of removal of segments of the gastro-intestinal tract on (LEVIN, MANSON, and LEVENE), A., ii, 63.
- in children (GROSSER), A., ii, 424.
- effect of subcutaneous administration of fat on (HEILNER), A., ii, 625.
- Metabolism, protein, in plants, influence of mineral salts on** (ZALESKI and ISRAILEVY), A., ii, 335.
- in ruminants, effect of non-protein nitrogen compounds on the (KELLNER, EISENKOLBE, FLEBBE, and NEUMANN), A., ii, 424.
- of parturient women (MURLIN and CARPENTER), A., ii, 729.
- purine (SCAFFIDI), A., ii, 626.
- in hibernating animals (KENNAWAY), A., ii, 728.
- in man and animals (MENDEL and LYMAN), A., ii, 973.
- of the monkey (WELLS), A., ii, 322.
- influence of ingestion of nucleic acid on (HIROKAWA), A., ii, 787.
- sugar, and pancreas, relation between (BALDWIN), A., ii, 224.
- Metal ammonia perchlorates** (SALVADORI), A., ii, 1002.
- Metal ammonia compounds, complex** (OSTROMISLENSKY and BERGMAN), A., i, 887; (WERNER), A., ii, 857, 960.
- Metallic carbonyls, properties of** (MOND, HIRTZ, and COWAR), T., 798; P., 67.
- cations, complex (HERTZ), A., ii, 611.
- hydroxides, amphoteric (WOOD), T., 878; P., 94.
- nitrides, electrical conductivity of (SRUKOFF), A., ii, 254.
- oxides, catalytic reactions by means of (MAILHE), A., i, 807.
- action of, on alcohols (SABATIER and MAILHE), A., i, 294.
- temperatures of reduction of (FAY, SEEKER, LANE, and FERGUSON), A., ii, 711.
- action of chlorine and carbon tetrachloride on (MICHAEL and MURPHY), A., ii, 1068.
- salts, fused, electrolytic dissociation of (LORENZ), A., ii, 259.
- secondary Röntgen rays from (GLASSON), A., ii, 674.
- action of, in physiological processes (HÖBER), A., ii, 330.
- silicates (JORDIS and LINCKE), A., ii, 418.
- sulphides, action of liquids which dissolve sulphur on (JORDIS and SCHWEIZER), A., ii, 405.
- Metalloids and metals, presence of, in drinking waters** (GARRIGOT), A., ii, 705.
- detection of, in mineral waters (GARRIGOT), A., ii, 549.
- Metals, spectra of the, in the electric arc** (HASSELBERG), A., ii, 811.
- change of the emissive power of, with the temperature in the ultra-red (RUBENS and HAGEN), A., ii, 762; (HAGEN and RUBENS), A., ii, 469.

- Metals**, dispersion and absorption of, for the visible and ultra-violet spectrum (MEIER), A., ii, 369.
 elasticity and hardening of (FAUST and TAMMANN), A., ii, 1039.
 determination of the optical constants of, from polarisation measurements (v. ULJANIN), A., ii, 812.
 internal friction of, at low temperatures (GUYE and SCHARPPE), A., ii, 486.
 viscosity of certain, and its variation with temperature (GUYE and MINTZ), A., ii, 591.
 influence of pressure on the boiling points of (GREENWOOD), A., ii, 390.
 thermal expansion and specific heat of (GRÜNEISEN), A., ii, 824.
 relation between size of the atoms of, and the temperature-coefficient of the resistance (STRINTZ), A., ii, 821.
 thermo-electric forces of solid solutions of (BERNOLLI), A., ii, 1030.
 electro-deposition of (PERKIN and HUGHES), A., ii, 898.
 galvanic ennobling of (VAN DEVENTER and VAN LUMMEL), A., ii, 179.
 formation of disperse systems by, under the influence of ultra-violet light and Röntgen rays (SVENNERG), A., ii, 277.
 modifications of, resulting from electrical disintegration in liquid argon (FISCHER and SOHRÖTER), A., ii, 809.
 solid solutions of, and the electron theory (SCHENCK), A., ii, 482.
 wet oxidation of (LAMBERT and THOMSON), T., 2428; P., 290.
 velocities of certain reactions between dissolved halogens and (VAN NAME and ENGAR), A., ii, 280.
 and their compounds, heat capacity of (SCHIMPF), A., ii, 181.
 solubility of gases in (SEKVERTS and KUMMHAAR), A., ii, 410.
 germicidal action of (RANKIN), A., ii, 282.
 new compounds of nitrogen with (FISCHER and SCHRÖTER), A., ii, 605.
 and alloys, contraction of, during cooling (WÜER), A., ii, 260.
 and metalloids, presence of, in drinking waters (GARRIGOU), A., ii, 705.
 and metalloids, detection of, in mineral waters (GARRIGOU), A., ii, 549.
 colloidal, preparation of, by means of acetaldehyde (CASTORO), A., ii, 620.
 colloidal, preparation of stable solutions of (SERONO), A., ii, 776.
 bivalent, action of salts of, on thiocyanates (BORGIOVANNI), A., i, 825.
- Metals**, Minoan, from the excavations of Crete (Mosso), A., ii, 955.
 of the tin group, separation of (CAVEN), P., 176.
 apparatus for the rapid electro-analytical separation of (SAND), A., ii, 65.
 separation of, by electrolysis (BUCK-MINSTER and SMITH), A., ii, 1112.
 precipitation of, by hydrogen sulphide (BRUNER and ZAWADSKI), A., ii, 944, 945.
Metastyrene (STOBEE and POSNJAK), A., i, 235.
Meteoric stone, from Chandakapur, structure and composition of (BOWMAN and CLARKE), A., ii, 788.
 from Simondium, Cape Colony (PRIOR), A., ii, 315.
Meteorite, new Pennsylvanian (FARRINGTON), A., ii, 420.
 from Angra dos Reis (LUDWIG and TSCHERMAK), A., ii, 315.
Methæmoglobin, morphological detection of, in blood (ERÖNG), A., ii, 623.
Methane, synthesis of (BONE and COWARD), T., 1219; P., 146.
 formation of, from hydrogen and carbon monoxide (GAUTIER), A., ii, 708.
 biological absorption of (GIGLIOLI and MASONI), A., ii, 485.
 rôle of, in organic life (SÖHNGEN), A., ii, 793.
 estimation of, electric combustion furnace for the (FRIES), A., ii, 904.
Methane, fluorodibromo-, and difluorobromo- (SWARTS), A., i, 293.
 tetranitro- (BERGER), A., i, 807.
 simple method of preparation of (CHATTAWAY), T., 2099; P., 164.
Methanedisulphonylbis-p-aminobenzeneazo- β -naphthol (MORGAN, PICKARD, and MICKLETHWAIT), T., 60.
Methanedisulphonylbis-p-aminobenzene-diazonium chloride and nitrate (MORGAN, PICKARD, and MICKLETHWAIT), T., 58.
Methanedisulphonylbis-p-nitroaniline (MORGAN, PICKARD, and MICKLETHWAIT), T., 58.
Methanedisulphonylbis-p-phenylenediamine (MORGAN, PICKARD, and MICKLETHWAIT), T., 58.
Methanedisulphonylbis-p-phenylenediacetamide (MORGAN, PICKARD, and MICKLETHWAIT), T., 60.
Methenesulphonic acid, amino-imino-, and its allyl derivative (BARNETT), T., 64.

- Methanesulphonyl-*p*-aminobenzenesulphonic acid** (MORGAN, PICKARD, and MICKLETHWAIT), T., 63.
- Methanesulphonyl-*p*-nitroaniline** (MORGAN, PICKARD, and MICKLETHWAIT), T., 61.
- Methanesulphonyl-*p*-phenylenediamine**, and its hydrochloride (MORGAN, PICKARD, and MICKLETHWAIT), T., 61.
- Methanesulphonyl-*p*-phenylenediazonide** (MORGAN, PICKARD, and MICKLETHWAIT), T., 62.
- α - and β -Methasone anhydrides**, and their derivatives (STRINKOFF, BOHRMANN, GRÜNNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 307.
- Methhebenine**, methosulphate and methiodide (PSCHORR and LOEWEN), A., i, 424.
- Methoxalanthranil** (BOBERT and GORTNER), A., i, 284.
- Methoxalanthranilic acid** (BOBERT and GORTNER), A., i, 284.
- o*-Methoxyacetophenone**, ω -chloro- (TUTIN), T., 2503; P., 244.
- p*-Methoxyacetophenone**, ω -amino-, hydrochloride, and other salts of (TUTIN), T., 2509.
- 5-Methoxy-*p*-anisylsalicylic acid**. See 5-Methoxy-2-*p*-methoxyphenoxybenzoic acid.
- 3-Methoxybenzaldehyde**, 2-hydroxy-, and its methyl ether (NOELTING), A., i, 177.
- 3-Methoxybenzaldehyde**, 2-hydroxy-, (*o*-vanillin) and its derivatives and condensation products (NOELTING), A., i, 176.
- Methoxybenzaldehydemeethoxydiphenylethyldrazone** (BUSCH and FLEISCHMANN), A., i, 283.
- 4-Methoxybenzhydrol**, 2,4-di-hydroxy-, its dipotassium salt and diacetyl and dibenzoyl derivatives (PORS and HOWARD), T., 973; P. 38.
- o*-, *m*-, and *p*-Methoxybenzoic acids**, menthyl esters of (COHEN and DUDLEY), T., 1739.
- 4-Methoxy-2-benzoylbenzoic acid**, 2'-hydroxy-, methyl ester (TAMBOUR and SCHÜRCH), A., i, 559.
- 2-Methoxy-(α)-benzoyliminocinnamic anhydride** (MAUTHNER), A., i, 113.
- 4-Methoxy-2-benzoylbenzoic acid**, 2'-hydroxy- (TAMBOUR and SCHÜRCH), A., i, 559.
- o*-Methoxybenzylidene-*p*-aminobenzoic acid**, and its ethyl ester (MANCHOT and FURLONG), A., i, 34.
- m*-Methoxybenzylidene-*p*-aminobenzoic acid**, *p*-hydroxy-, and its ethyl ester (MANCHOT and FURLONG), A., i, 33.
- o*-Methoxybenzylideneaniline** (NOELTING), A., i, 177.
- m*-Methoxybenzylideneaniline**, and 2-hydroxy-, and its methyl ether and 4-hydroxy- (NOELTING), A., i, 177.
- o*- and *p*-Methoxybenzylideneanthranilic acid** (WOLF), A., i, 736.
- 3-Methoxybenzylideneanthranilic acid**, 4-hydroxy- (WOLF), A., i, 736.
- 5-*p*-Methoxybenzylidene-3- ψ -cumyl- and 3-isohexyl-rhodanic acids** (KALUZA), A., i, 130.
- m*-Methoxybenzylidenedihydrazine**, and its phenylthiosemicarbazide (FRANZEN and EICHLER), A., i, 700.
- 4-*m*-Methoxybenzylidenemethyl-6-methyl-2-pyrimidone**, *p*-hydroxy-, and its salts (STARK and BÖGMANN), A., i, 437.
- m*-Methoxybenzylidene-*o*- and *p*-toluidine**, *p*-hydroxy- (MANCHOT and FURLONG), A., i, 33.
- p*-Methoxybenzylmalonic acid** and α -bromo- (FRIEDMANN and GUTTMANN), A., i, 741.
- 1- α -Methoxybenzyl-2-naphthol-3-carboxylic acid**, methyl ester of (FRIEDL), A., i, 742.
- p*-Methoxycinnamic acid**, 3,5-di-iodo-, and its salts and esters (WHEELER and JOHNS), A., i, 114.
- 2-Methoxycoumaran**, 4,6-dibromo- (FRIES and MOSKOFF), A., i, 332.
- Methoxycoumaranone** (FELIX and FRIEDLÄNDER), A., i, 279.
- 8-Methoxycoumarin** (NOELTING), A., i, 177.
- 3-Methoxy-1:1-dimethyl- Δ^2 -cyclohexenylidene-5-cyanoacetic acid**, and isomeric ethyl esters of (CROSSLEY and GILLING), T., 528.
- 5-Methoxy-1:3-dimethylhydantolmethylamide** (BLITZ), A., i, 523.

- Neutralisation**, discoverer of the law of (SPETER), A., ii, 947.
- Neutral salt action** (v. SZYSZKOWSKI), A., ii, 703.
- Nickel**, the system iron and (RUER and SCHÜZ), A., ii, 959.
- the system, iron, copper, and (VOGEL), A., ii, 616.
- the system, sulphur and (BORNEMANN), A., ii, 1072.
- absorption of carbon by, in the electrolysis of aqueous solutions (LAMBRIS), A., ii, 131.
- Nickel alloys** with copper (VIGOUROUX), A., ii, 182.
- with silver (VIGOUROUX), A., ii, 717.
- Nickel ore**, analysis of (BAUDISCH), A., ii, 77.
- Nickel salts**, magnetic susceptibilities of (FINKE), A., ii, 179.
- action of nitrites and hyposulphites on (BALL), P., 329.
- Nickel carbonyl**, interaction of, with carbon disulphide (DEWAR and JONES), T., 1226; P., 137.
- oxide, heat of formation of, and heat of combination of, with sodium oxide (MINTER), A., ii, 828.
- phosphides, two new (JOLIBOIS), A., ii, 132.
- wire, behaviour of, to hydrogen at high temperatures (v. PIRANI and MEYER), A., ii, 719.
- Nickelamine molybdenum cyanide** (ROSENHEIM, GARFUNKEL, and KOHN), A., i, 102.
- Nickel**, reactions of (ALVAREZ), A., ii, 454.
- detection of (BIANCHI and DI NOLA), A., ii, 1003.
- detection of, in the presence of much cobalt (BALL), P., 329.
- direct titration of (RUPP and PFENNING), A., ii, 458.
- gravimetric estimation of, in nickel steel (RHEAD), A., ii, 352.
- estimation of, in nickel steel (GROSSMANN and SCHÜCK), A., ii, 658.
- volumetric estimation of (JAMIESON), A., ii, 658.
- and cobalt, separation of (WERNER), A., ii, 352.
- electrolytic separation of (ALVAREZ), A., ii, 657; (BRUYLANTS), A., ii, 1114.
- Nickel steel**, estimation of nickel in (GROSSMANN and SCHÜCK), A., ii, 658.
- gravimetric estimation of nickel in (RHEAD), A., ii, 352.
- Nicotine**, absorption spectra of, as vapour, liquid, and in solution (PITREIS), T., 1035; P., 113.
- Nicotine**, mode of action of (HOLL), A., ii, 59.
- action of, on frog's muscle (LANGLEY), A., ii, 797.
- action of, on muscle, and antagonism of, by curarine (VELRY and WALLER), A., ii, 524.
- production of, in tobacco culture (SCHLOESING), A., ii, 743.
- Nitrates**. See under Nitrogen.
- Nitration**, studies in (TANGLE and BURKE), A., i, 21.
- Nitres**, estimation of chlorates in (FAGES VIRGILI), A., ii, 348.
- Nitric acid**. See under Nitrogen.
- Nitric compounds**, estimation of, in sulphuric acid (LÉO), A., ii, 71.
- Nitrides**. See also Metallic nitrides.
- Nitriles**, molecular complexity of, in the liquid state (TURNER and MERRY), P., 128.
- preparation of (REID), A., i, 109.
- alkylation of (BODROUX and TABOURY), A., i, 557.
- aliphatic, preparation of (ABDSORFF), A., i, 721.
- aromatic, synthesis of (BODROUX and TABOURY), A., i, 482.
- open chain, formation of imino-derivatives of cyclopentene from (MIRCHELL and THORPE), T., 907; T., 114.
- Nitrotrimethylsulphoxylic acid**, sodium, zinc, and calcium salts (CHEMISCHE FABRIK VON HEYDEN), A., i, 229.
- Nitrotrimethylsulphurous acid**, sodium salt (CHEMISCHE FABRIK VON HEYDEN), A., i, 229.
- Nitrites**. See under Nitrogen.
- Nitroamines**, aromatic, and allied substances, transformation of, and its relation to substitution in benzene derivatives (BRITISH ASSOCIATION REPORTS), A., i, 551.
- action of concentrated sulphuric acid on (REVERON), A., i, 255.
- Nitro-compounds**, reduction of (HELLER and FRANTZ), A., i, 848.
- by hydrogen sulphide (GOLDSCHMIDT and LARSEN), A., ii, 29.
- by spongy copper (MAILHE and MURAT), A., i, 830.
- with zinc dust and acetic acid (HELLER), A., i, 598.
- aliphatic (STEINROFF, BOHMANN, KIRCHHOFF, JÜRGENS, and BASEDEK), A., i, 305.
- aromatic, as precipitants for alkaloids (ROSENTHALER and GÜRNEL), A., ii, 557.

Nitro-compounds:—

- aromatic, relation between the absorption spectra and chemical constitution of (BALY, TUCK, and MARSDEN), T., 571; P., 51.
- Nitrogen, atomic weight of (GUYE and DROUGININE), A., ii, 1056.
- preparation of pure (FISCHER and HÄHNEL) A., ii, 608.
- refraction and dispersion of (CUTHBERTSON and CUTHBERTSON), A., i, 85.
- band spectrum of (CROZE), A., ii, 368; (ANGERER), A., ii, 561; (V. DEN HELM), A., ii, 811.
- canal-rays of, positive and negative ions in (WIEN), A., ii, 475.
- inversion points of (PORTER), A., ii, 592.
- atmospheric, method of collecting, (REBENSTONFF), A., ii, 604.
- and carbon dioxide, Andrews' compressibility curves for mixtures of (KNOTT), A., ii, 187.
- and hydrogen, compression of a mixture of (BRINER and WROCZYNSKI), A., ii, 707.
- and oxygen, analogies between derivatives of (ANGELI), A., ii, 844, 948.
- coefficients of absorption of, in distilled and sea water (FOX), A., ii, 29.
- vapour, saturated and supersaturated, data for (PLANK), A., ii, 706.
- new compounds of, with metals, and their atability in the light of the periodic system (FISCHER and SCHRÖTER), A., ii, 605.
- deposition of, in animals (FRISKE), A., ii, 64.
- the elimination of, following the administration of amino-acids, glycylglycine, and its anhydride (LEVENE and MEYER), A., ii, 53.
- excretion of the kidney (BARRINGER and BARRINGER), A., ii, 1091.
- distribution of, in the intestinal excreta (LABBE), A., ii, 1090.
- partition of, in human milk (FREHN), A., ii, 429.
- assimilation of, by bacteria (BOTTOMLEY; HOFFMANN and HAMMER), A., ii, 988.
- assimilation of, with cellulose or agar-agar as source of energy (PRINGSHEIM; PRINGSHEIM and PRINGSHEIM), A., ii, 230; (KOCH), A., ii, 536.
- free atmospheric, assimilation of, by plants (MAMELI and POLLACCI), A., ii, 645.
- ammonia and nitrates as sources of, for mould fungi (BITTER), A., ii, 230.

- Nitrogen, amide and other forms of, the relationship between, in ripe seeds (PANROZZANI), A., ii, 438.
- in soil. See under Soil.
- Nitrogen oxides, production of, by bacteria (TACKER), A., ii, 231.
- in atmospheric air at various altitudes (HAYHURST and PRING), T., 368; P., 92.
- peroxidation of, by ultra-violet light (BERTHELOT and GAUDERON), A., ii, 606.
- behaviour of, towards water and alkalis (FOERSTER and BLICH), A., ii, 1059.
- attempt to transform, into the corresponding calcium salts (TASSILLY and LEROIDE), A., i, 535.
- Nitrogen monoxide (*nitrous oxide*) (STAVENHAGEN and SCHUCHARD), A., ii, 774.
- compression of (BRINER and WROCZYNSKI), A., ii, 707.
- solubility of (FINDLAY and CRIGHTON), T., 536; P., 44.
- Nitrogen dioxide (*nitric oxide*), formation of, from air, in the electric arc (HOLWECH), A., ii, 578; (HABER, KOENIG, and PLATOU), A., ii, 1057; (HABER and PLATOU; HOLWECH and KOENIG), A., ii, 1058; (HABER and HOLWECH), A., ii, 1059.
- formation of, during the combustion of hydrogen (WOLKITSIN), A., ii, 1059.
- behaviour of, at low temperatures (ADWENTOWSKI), A., ii, 199.
- decomposition of (BRINER and WROCZYNSKI), A., ii, 120.
- compounds of, with cupric salts (MANCHOT), A., ii, 955.
- ferrous compounds of (MANCHOT and HUTTNER), A., ii, 414.
- compounds of, with iron and blood-pigment (MANCHOT), A., ii, 416.
- peroxide or tetroxide, analysis of (GUYE and DROUGININE), A., ii, 1056.
- a new sulphide of (BURT), T., 1171; P., 127.
- Nitric acid and nitrates, new colour test for (SCHMIDT and LUMPT), A., ii, 450.
- Nitrates, action of crushed quartz on solutions of (PATTEN), A., ii, 950.
- anhydrous, preparation of, by double decomposition (GUNTZ and MARTIN), A., ii, 497.
- absorption spectra of (SCHAEFFER), A., ii, 562.
- decomposition of, by bacteria (SEWERIN), A., ii, 143.

Nitrogea:—

- Nitrates**, manurial action of (KELLNER), A., ii, 340.
 detection of, in presence of bromides, iodides and ammonium compounds (GOLDSCHMIDT), A., ii, 344.
 detection of, in the presence of chlorates and bromates (TAMAYO), A., ii, 450.
 estimation of (POZZI-ESCOT), A., ii, 71, 155; (FARCY), A., ii, 71, 72; (LOMBARD), A., ii, 72; (CLARENS; CAHEN), A., ii, 752.
 estimation of, phenolsulphonic acid method for the (CHAMOT and PRATT), A., ii, 545; (POUGET), A., ii, 652.
 and other nitrogen compounds, analysis of (BRONNERT), A., ii, 1116.
 use of nitron in the analysis of (VASILIEFF), A., ii, 1109.
Nitrous acid, molecular weight of, in aqueous solution (SAPOSHNIKOFF), A., ii, 230.
Nitrites, ionisation of the, measured by the cryoscopic method (RAY and MUKHERJEE), P., 173.
 organic, preparation of (FERRARIO), A., ii, 707.
 manurial action of (KELLNER), A., ii, 340.
 estimation of, by the "sulphophenol" reagent (POUGET), A., ii, 652.
Nitrogen, detection of, in organic substances (ELLIS), A., ii, 997.
 estimation of very small amounts of (ZELLEN), A., ii, 70; (MITSCHERLICH), A., ii, 448; (DAVENPORT), A., ii, 998.
 estimation of, in amino-compounds (VAN SLYKE), A., ii, 751.
 estimation of, as ammonia (GRÉGOIRE), A., ii, 651.
 estimation of, by Kjeldahl's method (HEUBNER and WIGNEA), A., ii, 240; (HARRISON and SELBY), A., ii, 751; (BROWN), A., ii, 804.
 estimation of, in calcium cyanamide (STUTZER and SÖLL), A., ii, 1009.
 estimation of, in explosives (POPPERBERG and STEPHEN), A., ii, 451.
 estimation of, in foods (ESSELS), A., ii, 448.
 estimation of, by means of formaldehyde titration (DE JACOB), A., ii, 751.
 estimation of ammoniacal, in meat (PENNINGTON and GREENLEE), A., ii, 449.

- Nitrogen**, estimation of, in nitrates (POZZI-ESCOT), A., ii, 155; (SALLE), A., ii, 451; (FERRARIO), A., ii, 652.
 estimation of, in smokeless powders (BERL and JURRIESEN), A., ii, 240.
 estimation of ammoniacal, in urine (HUGUET), A., ii, 155; (BENEDICT and SAIKI), A., ii, 166; (ROSA and OTTENBURG), A., ii, 449.
 influence of chlorides on the estimation of, as nitrates (STEWART and GRAVES), A., ii, 652.
Nitrogen compounds, tervalent, molecular complexity of, in the liquid state (TURNER and MERRY), T., 2069; P., 220.
 stereoisomeric tervalent, a supposed case of (JONES and WHITE), T., 632; P., 57.
Nitrogen linking with carbon (BUTZ), A., i, 524.
Nitrogenous metabolism. See under Metabolism.
Nitro-group, displacability of the (PONZIO), A., i, 339.
 replacement of halogen by the (RATFORU and HEYL), A., i, 373, 739.
 the side valency of the (HOPMANN and KIRMUTHNER), A., i, 548.
 reduction of. See under Nitro-compounds.
Nitrohydroxy-derivatives, aromatic, preparation of (WOLFFSTEIN and BOEYERS), A., i, 27.
Nitrometer for estimating urea, modification of the (MOSSLER), A., ii, 663.
Nitron. See 1:4-Diphenyl-3,5-cyanilo-4:5-dihydro-1:2:4-triazole.
Nitron process, estimation of potassium nitrate in meat by the (PAAL and GANGHOFFER), A., ii, 453.
Nitrosates, action of hydroxylamine on (CUSMANO), A., i, 655, 865.
Nitrosoamides, reaction of, with phenylhydrazine (WILLSTÄTTER and STOLL), A., i, 134.
Nitrosoamines, stable primary (HELLER and SOURELIS), A., i, 749.
Nitrosobacteria, biology and chemistry of (GAGE), A., ii, 531.
Nitrosochlorides, action of hydroxylamine on (CUSMANO), A., i, 655, 865.
C-Nitroso-compounds, historical notes on (RAMBERGER), A., i, 706.
Nitroaryl chloride, formation of (BRUNER and WRÓCZYŃSKI), A., ii, 120.
 reduction of (JONES and MATHEWS), A., ii, 1090.
Nitrous acid. See under Nitrogen.
Nomenclature of inorganic compounds (HOFFMANN), A., ii, 198.

Nonadecyl alcohol, from Japan tallow (MATTHEWS and HEINTZ), A., i, 150.
 Nonamethoxytriphenylmethane (FABINYI and SZÁKI), A., i, 837.
 Non-electrolytes, diffusion of (ÖHOLM), A., ii, 273.
 osmotic pressure of concentrated solutions of (SACKUR), A., ii, 273.
 depression of electrical conductivity by (ARMSTRONG and CROTHERS), P., 299.
 influence of, on enzymic activity (ARMSTRONG and ARMSTRONG), P., 334.
 mixtures of, with water, free energy of chemical action in (PISSARJEVSKY and ZEMBIKSKY), A., ii, 595.
 solubility of potassium sulphate in concentrated aqueous solutions of (FOX and GAUGE), T., 377; P., 27.
 Δ¹-Nonenoic acid (HALLER and BROCHET), A., i, 216.
 and its esters and derivatives (HARDING and WEIZMANN), T., 299; P., 24.
 α-Nonoic acid, condensation products of, with glycine, alanine and leucine (HOPWOOD and WEIZMANN), P., 69.
 α,β-dibromo- (HARDING and WEIZMANN), T., 302.
 β-hydroxy-, and its silver salt (HALLER and BROCHET), A., i, 216.
 and its ethyl ester (HARDING and WEIZMANN), T., 302.
 α-Nonoyl chloride, α-bromo- (HOPWOOD and WEIZMANN), P., 69.
 α-Nonoylglycine, α-amino-, and α-bromo- (HOPWOOD and WEIZMANN), P., 69.
 Δ¹-Nonolenic acid. See Δ¹-Nonenoic acid.
 Nopie acid, a reaction of (FERNÁNDEZ), A., ii, 1119.
 Noreksantalal and its acetate and semicarbazone (SEMMLER and ZAAR), A., i, 573.
 Nortricloeksantalal, derivatives of (SCHIMMEL & Co.), A., i, 753.
 Noreksantallic acid, and its methyl ester (SEMMLER), A., i, 496.
 Noreksantalol (SEMMLER and ZAAR), A., i, 573.
 Nourishment, assimilation of natural and artificial (ORGLER), A., ii, 1084.
 Nucleic acid, presence of iron in (SAUERLAND), A., i, 845.
 from yeast, composition of (KOWALEVSKY), A., i, 906.
 uric acid combinations with (SCHITTENHELM), A., i, 341.
 fate of, in the organism (FRANK and SCHITTENHELM), A., ii, 52.
 influence of, on the nitrogen metabolism of rabbits (SCHITTENHELM and SEISSER), A., ii, 423.
 behaviour of, in the cleavage of the sea-urchin's egg (MASING), A., ii, 731.

Nuclein bases, behaviour of, in the dark in plants (KIESEL), A., ii, 800.
 Nucleo-protein of milk glands, scission products of (MANDEL), A., i, 147.
 of spleen (SATO), A., ii, 56.
 in the yolk platelets of the frog's egg (McCLENDON), A., ii, 54.
 Nupharine, extraction of (GORIS and CRÉTÉ), A., i, 419.
 Nutritive solutions, influence of the mineral constituents of, on *Asotobacter* (KUZKMIENIEWSKA), A., ii, 987.

O

 α -Phenonaphthacarbazole-8-sulphonic acid (BUCHERER and SONNENBERG), A., i, 145.
 11-Phenonaphthacenequinone, 5:12-di-hydroxy- (VOSWINCKEL and DE WEEERT), A., i, 50.
 8-Phenonaphthaxanthone hydrobromide (GOMBERG and CONE), A., i, 872.

- Phanoquinone, hexabromo- (OLIVIER), A., i, 80.
- Phenorassamine chloride. See 9-Phenyl-xanthinid chloride; 3-6-diamino.
- Phenothiazethionium, diaminobenzoylamine, chloride (MITSUGI, BEYSCHLAG, and MÖHLAU), A., i, 338.
- Phenothiazine, diaminobenzoylamine, and its stannichloride, and other salts; dinitrobenzoylamine, and dinitrobenzoylamine- (MITSUGI, BEYSCHLAG, and MÖHLAU), A., i, 338.
- Phenoxozone (diphenylene dioxide), preparation of: (FARBENFABRIKEN VORM. F. F. BAYER & Co.), A., i, 784.
- o*-Phenoxyacetyloxybenzoic acid (CHEMISCHE FABRIK VON HEYDEN), A., i, 486.
- 2-Phenoxybenzoic acid, 4-bromo- (GOMBERG and CONE), A., i, 58.
- 4-Phenoxybenzoic acid, 2:4'-dinitro, and its silver salt (COOK), A., i, 781.
- 1-*o*-Phenoxybenzyl-2-naphthol-3-carboxylic acid, methyl ester of (FRIEDL), A., i, 742.
- 4-(or 1)-Phenoxy-3-methylanthraquinone, 1-(or 4)-chloro-8-hydroxy- (WALSH and WEIZMANN), T., 690.
- γ -Phenoxy- α -phenylpropane, β -hydroxy- (FOURNEAU), A., i, 246.
- α -Phenoxypropane, γ -chloro-8-hydroxy-phenylurethana of (BOYD and MARLE), T., 1789; P., 209.
- Phenoxypropanolamines, (BOYD), T., 1791; P., 209.
- β -Phenoxyisopropyl alcohol, β -amino, and its salts (BOYD), T., 1791; P., 209.
- Phenoxypropylenebromohydrin (FOURNEAU), A., i, 246.
- Phenyl acetate, 4-bromo-2-nitro, 4-bromo-2:6-dinitro, 2-bromo-4-nitro, and 2-bromo-4:6-dinitro- (VAN ERP), A., i, 618.
- sodium carbonate, action of acetone on (MÖLL VAN CHARANTR and MONTAGNE), A., i, 311.
- benzyl ether (v. MEYER), A., i, 316.
- ether, tetrabromo- (COOK), A., 781.
- decabromo- (BONNEAU), A., i, 670.
- 2:4-dinitro, and trinitro, and derivatives (COOK), A., i, 731.
- ethers, action of bromine on, in the presence of aluminium bromide (BONNEAU), A., i, 669.
- derivativea of, with glycerol (FOURNEAU), A., i, 246.
- Phenyl ethers, *p*-chloro-*o*-amino-, 2- and 4-chloro-2'-amino-, 2- and 4'-chloro-4'-amino-, 4:2'- and 4:4'-dichloro-2'-amino-, 2:4'-dichloro-4-amino-, and their derivatives (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 312.
- ethyl ether. See Phenetole.
- glycide ether, *p*-nitro- (FOURNEAU), A., i, 247.
- mercaptan, interaction of, with thionyl chloride (TASKER and JONES), P., 234.
- m*-hydroxy-, and its lead salt (v. SZATHMÁRY), A., i, 733.
- propyl ether, pentabromo- (BONNEAU), A., i, 670.
- o*-, *m*-, and *p*-tolyl ethers, 2- and 4-amino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 374.
- m*- and *p*-tolyl ethers, *p*-chloro-, and their sulphonic acids (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 312.
- p*-tolyl ether, 2:4-dinitro-, and its derivatives (COOK), A., i, 731.
- sulphide, action of hydrogen peroxide on (HINSBERG), A., i, 164.
- chloro-hydroxy- (GAZDAR and SMILES), T., 2252.
- vinyl ether (WOHL and BERTHOLD), A., i, 620.
- Phenylacenaphthaphenazonium, and 2-amino-, and 3-chloro-, and their derivatives and salts (ULLMANN and CASSEIRER), A., i, 202.
- Phenylacetaldehyde, α -cyano- (BODROUX), A., i, 623.
- Phenylacetamide, *o*-bromo- α -nitro-, potassium salt of, and α -*o*-di-bromo- α -nitro- (WISLICENUS and FISCHER), A., i, 622.
- o*-nitro- (TSCHORR and HOPPE), A., i, 737.
- Phenylacetic acid, behaviour of, in fowls (TOTANI), A., i, 880.
- menthyl ester of (COHEN and DUDLEY), T., 1749.
- Phenylacetic acid, α -amino-*p*-hydroxy-, and its salts (ALOY and RABAUT), A., i, 558.
- α -bromo- α -amino- (WISLICENUS and FISCHER), A., i, 622.
- oximinonitro-, ethyl ester, and its derivatives (SCHMIDT and DIETTERLE), A., i, 815.
- dithio-, methyl ester (HOUBEN and SCHULTZE), A., i, 711.
- Phenylacetonitrile (benzyl cyanide), synthesis by means of (BODROUX and TABOURY), A., i, 257.
- action of benzaldehyde on the sodium derivative of (BODROUX and TABOURY), A., i, 622.

- Phenylacetoneitrile** (*benzyl cyanide*), action of esters of monobasic aliphatic acids on the sodium derivative of (BODROUX), A., i, 623.
- Phenylacetoneitrile**, *o*-amino-, and its derivative (PSCHORR and HOPPE), A., i, 737.
- o*-bromo-, condensation of ethyl nitrate with, and *o*-bromo-*o*-nitro-, and its methyl ether and sodium and potassium salts (WISLIGENUS and FISCHER), A., i, 621.
- Phenylaceturic acid**, *p*-chloro- (FRIEDMANN and MAASE), A., ii, 795.
- Phenylacetylaminomethylcarbinol** (PICTET and GAMS), A., i, 774.
- Phenylacetyl- β -3-methoxy-4:5-methyl-enedioxypheylethylamine** (SALWAY), T., 1213.
- Phenylalanine**, *m*-chloro- (FLATOW), A., ii, 321.
- p*-chloro-, and its hydrochloride and benzoyl derivative (FRIEDMANN and MAASE), A., ii, 794.
- Phenyl- β -alanine**, 2:4-dinitro- (ABERHALDEN and BLUMBERG), A., i, 371.
- Phenylalkylamines**, *o*-dihydroxy-, optically inactive, preparation of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 372, 664.
- Phenylalkylnitroamines**, *trinitro*- (FRANCHIMONT), A., i, 617.
- Phenyl α -aminopropyl ketone**, hydrochloride, picrate and platinichloride of (HILDESHEIMER), A., i, 891.
- α -Phenylamylamine**, and its derivatives (v. BRAUN), A., i, 844.
- 1-Phenyl-2-isocamylurazole** (BRUNEL and ACHRE), A., i, 521.
- Phenyl-*p*-anisidine**, tribromo- (WIELAND and WICKER), A., i, 243.
- β -Phenyl- α -anisyl- $\Delta\alpha$ -butene- γ^2 -dianil** (BORSCH and TITSINGH), A., i, 65.
- α -Phenyl- β -anisyl- $\Delta\alpha$ -butene- γ^2 -dianil** (BORSCH and TITSINGH), A., i, 66.
- Phenyl-*p*-anisylethylene**, dibromo-derivative of (BURIGNIES), A., i, 668.
- 2-Phenyl- β -anisylpyridine** (SCHOLTZ and MEYER), A., i, 562.
- β -Phenyl- β -*o*-anisylthiosemicarbazide**, and its *m*-nitrobenzylidene derivative (BUSCH and REINHART), A., i, 77.
- Phenyl-*p*-anisyl-3:4-gem-triazoleisooxazole** (WIELAND, GELIN, and ROSEU), A., i, 785.
- Phenylarsenous oxide**, *p*-hydroxy- (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 148.
- p*-iodo- (MAMELI and PATTA), A., i, 531.
- Phenylarsinic oxide**, *p*-amino-, condensation product of, with β -naphthylquinonesulphonic acid. (EHRLICH, BERTHEIM, and SCHMITZ), A., i, 452.
- Phenylarsinic acid** and its derivatives, reduction products of (EHRLICH, BERTHEIM, and SCHMITZ), A., i, 451.
- Phenylarsinic acid**, *o*-amino- (*o*-arsanilic acid) 4-chloro- (BENDA), A., i, 148.
- p*-amino- (*arsanilic acid*) caramide and thiocarbamide derivatives of (FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING), A., i, 148.
- mono*- and *di*bromo-, *dichloro*-, *mono*- and *di*-iodo- (BERTHEIM), A., i, 346.
- Phenylarsinoacetic acid**, *p*-amino- (EHRLICH, BERTHEIM, and SCHMITZ), A., i, 452.
- Phenylasparagine**, 2:4-dinitro- (ABERHALDEN and BLUMBERG), A., i, 371.
- Phenylbenziminazole-*o*-carboxylic acid**. See Benziminazole-2-benzoyl acid.
- Phenyl- ψ -azimino benzene**. See 2:1:3-Benzotriazole.
- Phenyl-2-azimino naphthalene-5:7-di-sulphonic acid**, *p*-nitro-, and *p*-amino- (GESELLSCHAFT FÜR CHEMISCHE INDUSTRIE IN BASEL), A., i, 207.
- Phenyl-2-azimino-5-naphthol-7-sulphonic acid**, *p*-amino-, preparation of (GESELLSCHAFT FÜR CHEMISCHE INDUSTRIE IN BASEL), A., i, 206.
- 3:4-Phenylazimino-6-phenylisoxazole**. See Diphenyl-3:4-gem-triazole-isoxazole.
- Phenylazolide**, *o*- and *m*-bromo- (DIMROTH and PFISTER), A., i, 904.
- 1-Phenyl-1:2:3-benzotriazole-5-sulphonic acid** (SCHWABE and WOLFF), P., 340.
- 2-Phenyl-1:3-benzoxazine-4-one** (TITHERLEY), T., 200; P., 9.
- 6*-bromo- (HUGHES and TITHERLEY), P., 344.
- 6*-chloro- (TITHERLEY and HUGHES), T., 1376; P., 175.
- 6-Phenyl-1:2:3:7:9-benzopentazole**, 4-hydroxy- (BÜLOW), A., i, 81.
- 1-Phenyl-benzsulphonitriene** (ULLMANN and GROSS), A., i, 886.
- 2-Phenyl-2:1:3-benzotriazole**, 5-amino-, 6-chloro-5-nitro-, 4:5:7-trichloro-6-hydroxy-, and 4:5-dichloro-6:7-dihydroxy- (ZINCKE and SCHARFF), A., i, 141.
- Phenylbenzylacetone**, 4:4'-dichloro- (STRAUS, KRIER, and LETZ), A., i, 567.
- β -Phenyl- α -benzylglutaconic acid** and its barium and silver salts (FEIST and POMME), A., i, 39.

4. Phenyl- γ -benzylidenembutyric acid, β -hydroxy, methyl ester and its bromide, and γ -bromo- β -hydroxy, methyl ester (KÖHLER and HERITAGE), A., i, 484.
5. Phenyl- α -benzylideneglutaconic acid (FEIST and POMME), A., i, 39.
1. Phenyl-4-benzylidene-3-methyl-5-pyrazolone-2'-carboxylic acid (MICHAELIS, KRUG, LEO, and ZIESEL), A., i, 514.
1. Phenyl-4-benzylidene-3-methyl-5-pyrazolone-3' and 4'-carboxylic acid (MICHAELIS and HORN), A., i, 517.
8. Phenyl- γ -benzylidenevaleric acid, β -hydroxy, methyl ester (KÖHLER and HERITAGE), A., i, 484.
- Phenylbenzyl ketone, semicarbazone of (SENDERENS), A., i, 489.
2. Phenylbenzyl-6-methyl-*n*-propyl-pyridinium iodide (SCHOLTZ), A., i, 634.
5. Phenyl- β -benzylpropionic acid, and its silver salt (RUHMANN), T., 460.
3. Phenyl- α -benzyl- α -propylpropionbenzene (HALLER and BAUER), A., i, 490.
- Phenylbenzyl sulphoxide (PUMMERER), A., i, 463.
- Phenylbiuret, *p*-bromo- (BÖSEKEN and COUVERT), A., i, 645.
3. Phenyl- γ -bromobenzylidenembutyric acid, β -hydroxy, methyl ester (KÖHLER and HERITAGE), A., i, 484.
1. Phenyl-1-*p*-bromophenylpyrazoline (AUWERS and VOSS), A., i, 70.
1. Phenyl- β -*m*-bromophenylthiosemicarbazide (BUSCH and REINHARDT), A., i, 76.
- Phenyl-*p*-bromoquinoxanthanol bromide hydrobromide (GOMBERG and CONE), A., i, 58.
- Phenyl-*p*-bromoxanthanol and its bromide (GOMBERG and CONE), A., i, 58.
- Phenylisobutane, 1- α -*di*hydroxy- (McKENZIE and WREN), T., 431.
- Phenylbutan- β -one, semicarbazone of (SENDERENS), A., i, 489.
- benzylbutylamine, *tri*nitro- (FRANCHIMONT), A., i, 616.
- Phenylbutylamine, and its derivatives (v. BRAUN), A., i, 844.
- benzylbutyl cyclohexyl ketone (KÖHLER and BURNLEY), A., i, 392.
- benzylbutyl nitroamine, *tri*nitro- (FRANCHIMONT), A., i, 616.
- Phenyl-2 and 4-*n*- and isobutylurazole, and their silver salts (BRUNEL and ACHÉE), A., i, 521.
- Phenylbutyric acid, preparation of (RUPE and PROSKE), A., i, 367.
- γ -Phenylbutyronitrile (v. BRAUN), A., i, 844.
- Phenylcamphoramic acid, *p*-hydroxy, isomeric forms of (PIUTTI, LEONE, and D'EMILIO), A., i, 675.
- Phenyl- α -camphoramic acid, 3-amino, and its hydrochloride and acetyl derivative, 4-hydroxy, and 3-nitro- (WOOTTON), T., 413.
- Phenylcampherimide, *p*-hydroxy- (PIUTTI, LEONE, and D'EMILIO), A., i, 675.
- Phenylcarbamic acid, 5-hydroxy-methyl ester of (CARLINFANTI), A., i, 733.
- chloro- and bromo- substituted propyl and isopropyl esters of (JOHNSON and LANOLEY), A., i, 885.
- Phenylcarbamide, action of chlorine on, and 2:4:6-trichloro- (CHATTAWAY and CHANEY), T., 292; P., 22.
- Phenylcarbamylfurylpyrazolone (TORREY and ZANETTI), A., i, 892.

- Phenylsulphoxyacetic acid and its ethyl ester (PUMMERER), A., i, 468.
- α -Phenylsulphoxypropionic acid (PUMMERER), A., i, 468.
- Phenyltartramic acid, *m*-nitro-, compound with *m*-nitroaniline (TINGLE and BURKE), A., i, 21.
- p*-nitro- (TINGLE and BURKE), A., i, 22.
- Phenyltetrahydroxazolone (SCHROETER), A., i, 431.
- Phenylthiobiuret, *p*-bromo- (BOESKEN and COUVERT), A., i, 645.
- Phenylthiocarbamic acid, allyl, methyl and benzyl esters (ROSCHERTVENSEN), A., i, 107.
- N*-Phenylthiodiphenylamine (BARNETT and SMILES), T., 564.
- Phenylthioglycol-*p*-arsinic acid (FARBWERKE FORM. MEISTER, LUCIUS, & BRÜNING), A., i, 452.
- Phenylthiolacetic acid, ethyl and methyl esters (PUMMERER), A., i, 468.
- Phenylthiolbenzoic acid, *o*-4', and 5'-chloro-2'-nitro-, *o*-2':4'-dinitro- and *o*-2':4'-6'-trinitro- and their methyl esters (MAYER), A., i, 261.
- 2-Phenylthiol-4-bromobenzoic acid (GOMBERG and CONE), A., i, 871.
- α -Phenylthiolpropionic acid, ethyl ester, (PUMMERER), A., i, 468.
- 9-Phenylthioxanthanol, 4-bromo- (GOMBERG and CONE), A., i, 871.
- 9-Phenylthioxanthanyl chloride and its derivatives, perchlorate, 4-bromo-, bromide and 4-chloro-, chloride (GOMBERG and CONE), A., i, 870, 871.
- Phenyl-*p*-tolylallylcarbinol (KUZMIN), A., i, 109.
- 3-Phenyl-*o*-tolyl- α -benzylidenethiosemicarbazide (BUSCH and REINHARDT), A., i, 75.
- α -Phenyl- α -*p*-tolylbutane- γ -triol (KUZMIN), A., i, 110.
- Phenyl-*o*- and -*m*-tolylloxamide (SUIDA), A., i, 665.
- Phenyl-*p*-tolylloxamide, *p*-indo-, and 4:2'-dinitro- (SUIDA), A., i, 665.
- 3-Phenyl-*o*-tolylpropionic acid, 3-hydroxy-, and its salts (KUZMIN), A., i, 110.
- 3-Phenyl-1-*o*-tolylpyrazole, 5-chloro- (MICHAELIS and LEO), A., i, 515.
- 3-Phenyl-1-*o*-tolyl-5-pyrazolone (MICHAELIS and LEO), A., i, 515.
- Phenyl-*p*-tolylpyrrolinophenazine (KUEHMANN), T., 1444.
- 3-Phenyl-*o*-tolyl- α -*m*-, and -*o*-tolylthiosemicarbazides (BUSCH and REINHARDT), A., i, 75.

- Phenyltriazene, *o*-, *m*-, and *p*-bromo-, and the copper derivative of the latter (DIMROTH and PFISTER), A., i, 904.
- 1-Phenyl-1:3:5-triazine, 3:6-diamino-, and its picrate (RACKMANN), A., i, 397.
- Phenyl-2:1:4-triazine-3-one, 5:6-di-*p*-bromo-, and its sodium and acetyl derivatives (BLITZ, EDLFSSEN and SEYDEL), A., i, 570.
- Phenyltriazacetic acid, and its ethyl ester (FORSTER and MÜLLER), T., 138; P., 4.
- 3-Phenyl-1:2:4-triazole, 5-bromo- (MANCHOT), A., i, 442.
- 4-Phenyl-1:2:3-triazole, and its silver salt, hydrochloride and platinumchloride (OLIVERI-MANDALÀ and COPPOLA), A., i, 594.
- 4-Phenyl-1:2:3-triazole-5-carboxylic acid, and its barium salt (OLIVERI-MANDALÀ and COPPOLA), A., i, 594.
- Phenyltriazomalonic acid, and its ethyl ester and amide (FORSTER and MÜLLER), T., 135; P., 4.
- Phenyltriazomethylcarbamids (FORSTER and MÜLLER), T., 1065; P., 113.
- Phenyl-1:2:4-triazylhydrazine, and its derivatives (MANCHOT), A., i, 442.
- Phenyltridocylnitrosoamine (LESUEUR), T., 2140.
- Phenyl-*N*-trimethylalanine, methyl ester, platinum- and aurichlorides of (ENGELAND), A., i, 343.
- 1-Phenyl-2:3:4-trimethyl-5-pyrazolone, *p*-nitro- (FARBWERKE VORM. MEISTER, LUCIUS, and BRÜNING), A., i, 78.
- 4-Phenyltriphenylmethane (SCHLENK, WEICKEL, and HERZENSTEIN), A., i, 237.
- 4-Phenyltriphenylmethyl, and its peroxide (SCHLENK, WEICKEL, and HERZENSTEIN), A., i, 236.
- 3-Phenylvaleronitrile (v. BRAUN), A., i, 844.
- Phenyl- α -valine, 2:4-dinitro- (ABDERHALDEN and BLUMBERG), A., i, 371.
- 9-Phenylxanthone, 9-chloro-2:8-dihydroxy-, and its derivatives (v. BAeyer, AICKELIN, DIEHL, HALLENSLEBEN, and HESS), A., i, 253.
- 3-hydroxy-, and its acetate and benzoate (KAUFFMANN and PANKWITZ), A., i, 394.
- 3:6-dihydroxy- (POPE and HOWARD), T., 61.
- 9-Phenylxanthone-9-ol, and *p*-chloro-, and their derivatives and salts (GOMBERG and CONG), A., i, 56.
- 4-hydroxy-, and 1:8-dihydroxy-, and its chloride (v. BAeyer, AICKELIN, DIEHL, HALLENSLEBEN, and HESS), A., i, 251.
- 9-Phenylxanthonium, 3-amino-6-hydroxy-, and 3:6-diamino-, chlorides and platinumchlorides (KEHRMANN and DENGELER), A., i, 407.
- α -, and 8-2-Phenyl-1-*o*-xylylene-6-methylpiperidinium, bromides and platinumchlorides (SCHOLTZ), A., i, 635.
- Phenyl-*m*- and -*p*-xylyloxamide (SUIDA), A., i, 665.
- Phillipsite, from Sirgwitz, Silesia (BARRIER and GONNARD), A., ii, 418.
- α - and 8-Phlophen, formation of (NIHRENSTEIN and WEBSTER), A., i, 124.
- Phloridin, behaviour of, after extirpation of the kidneys (LESCHKE), A., ii, 530; (GLAESNER and PICK), A., ii, 639, 1094.
- Phloridzin diabetes. See under Diabetes.
- Phloridzin glycocholia (WOODYATT), A., ii, 227.
- Phloroglucinol, derivatives of (FISCHE), A., i, 243.
- amino-, hydrochloride of (LEUCHE and THEODORESCU), A., i, 386.
- trithio-, derivatives of (POLLAK and TUGAROVIC), A., i, 734.
- Phloroglucinoldicarboxylic acid, dimethyl ester and its amide (LEUCHE and THEODORESCU), A., i, 386.
- Phorone monooxide (HARRIES and TÜRK), A., i, 608.
- Phosphates. See under Phosphorus.
- Phosphatides, influence of alcohol on the quantity of, in animal organs (SIEBER), A., ii, 147.
- the importance of, for the living cell (KÖCH), A., ii, 142.
- of horse pancreas (FRÄNKEL and OFFER), A., i, 600.
- and cerebrosides, properties of a mixture of, compared with those of protagon (CRAMER), A., i, 296.
- Phosphorescence (URBAIN), A., ii, 765.
- relation between absorption and (BRÜNINGHAUS), A., ii, 88.
- theory of the law of the optimum of (BRÜNINGHAUS), A., ii, 89.
- progressive, at a low temperature (DE KOWALSKI), A., ii, 1016.
- of some inorganic salts (WILKINSON), A., ii, 5.
- of uranyl salts at very low temperatures (BECQUEREL, BECQUEREL, and ONNES), A., ii, 371.
- of organic compounds on spontaneous oxidation (DELÉPINE), A., i, 295, 545, 612.
- of dialkylthiocarbonates (BILLETZ), A., i, 544.
- restoration of, to sulphides of the alkaline earths (GARNET), A., ii, 173.

- Phosphoric acid. See under Phosphorus.
- Phosphorites, French, mineralogical constitution of (LACHOIX), A., ii, 720.
- Phosphorus, atomic weight of (BAXTER and JONES), A., ii, 238.
- allotropic forms of, (STOCK), A., ii, 288.
- colloidal preparation of (v. WEIMARN and MALJISHEFF), A., ii, 941.
- black, nature of (GERNEZ), A., ii, 707.
- Hittorf's and red (STOCK and GOMOLKA), A., ii, 30.
- white, behaviour of, at low temperatures (COHEN and INOUE), A., ii, 406.
- white, red, and pyromorphic, relations between (JOLIBOIS), A., ii, 846.
- oxidation of (JONES and VAN KESSEMA), A., ii, 31.
- transformation of, in the cardiol ultramicroscope (SIEDENTOFF), A., ii, 280.
- in beef (FRANCIS and TROWBRIDGE), A., ii, 731, 792.
- in feces (LIPSCHUTZ), A., ii, 227.
- organic, the content in, of ripe seeds (PARROZZANI), A., ii, 438.
- excretion of, in urine (KONDO), A., ii, 1091.
- in yeast (BUCHNER and HAEHN), A., ii, 989.
- Phosphorus compounds, heated, emission of positive rays from (HORTON), A., ii, 176.
- with iron (KONSTANINOFF), A., ii, 130; (KUNN), A., ii, 131.
- Phosphorus chloride, a new (BESSON and FOURNIER), A., ii, 121.
- pentachloride, action of, on unsaturated compounds (CLARKE), *Tr.*, 890, p. 96.
- suboxide (STOCK), A., ii, 121.
- Phosphoric acid, alkali and water, equilibria in the systems (D'ANGE and SCHREINER), A., ii, 1050.
- detection of, in wines (HUBERT and ALBA), A., ii, 651.
- estimation of, iodometrically (ABTMANN and BRANDIS), A., ii, 241; (BRANDIS), A., ii, 345.
- in silicic slugs and native phosphates (GUERRY and TOUSSAINT), A., ii, 73.
- by means of silver nitrate (WILKIE), A., ii, 752.
- Phosphates, influence of, on the respiration of plants (IVANOFF), A., ii, 438.
- function of, in alcoholic fermentation (HARDEN and YOUNG), A., ii, 643.
- Phosphorus chloride:—
- Phosphates, insoluble, of the soil, the co-operation of micro-organisms in the utilisation of, by higher plants (DE GRAZIA), A., ii, 436.
- effect of soluble salts on (GRAVES), A., ii, 444.
- detection of, in tissues (LIESERGAUS), A., ii, 1085.
- commercial analysis of (WILKIE), A., ii, 753.
- gravimetric estimation of (MATTHE), A., ii, 653.
- alkali, estimation of, by direct titration (POZZI-ESCOFF), A., ii, 245.
- native, estimation of total phosphoric acid in (GUERRY and TOUSSAINT), A., ii, 73.
- Phosphoric acids, ortho-, meta-, and pyro-, reciprocal transformations of (BALAREFF), A., ii, 607.
- Orthophosphoric acid, and metaphosphoric acid, relation between composition and conductivity in solutions of (PRIDEAUX), A., ii, 12.
- Metaphosphoric acid, hydration of (BALAREFF), A., ii, 951.
- ethyl ester, and its use in organic chemistry (LANGHELD), A., ii, 536.
- Hypophosphoric acid, formula of (CORNER), A., ii, 121.
- preparation of (CAVALIER and CORNER), A., ii, 31.
- preparation, molecular weight and benzyl and guanidine salts of (ROSENHEIM and PINSKER), A., ii, 708.
- estimation of (ROSENHEIM and PINSKER), A., ii, 73.
- Monophosphoric acid (SCHMIDLIN and MASSINI), A., ii, 498.
- Paraphosphoric acid, (SCHMIDLIN and MASSINI), A., ii, 498.
- Phosphorous acid, detection of, in organs (EHRENFELD and KULKA), A., ii, 59.
- estimation of (ROSENHEIM and PINSKER), A., ii, 73.
- Hypophosphorous acid, detection of, in organs (EHRENFELD and KULKA), A., ii, 59.
- estimation of (ROSENHEIM and PINSKER), A., ii, 73.
- Hypophosphites, decomposition of water by, in presence of palladium (BACH), A., ii, 31.
- behaviour of, in the organism (PADUA), A., ii, 432.
- Superphosphates, estimation of free acid in (GUTHRIE and RAMSAY), A., ii, 72.
- Selenophosphates (EPHRAIM and MAJLER), A., ii, 206.

iosphorus pentasulphide (STOCK and
 HERSCOVICI), A., ii, 499.
 Tetraphosphorus tri- and hepta-sul-
 phides (STOCK and RUDOLPH; STOCK
 and HERSCOVICI), A., ii, 200.
 Phosphoryl chloride as a cryoscopic
 solvent (WALDEN), A., ii, 1036.
 Thiophosphates (EPHRAIM and
 MAJLER), A., ii, 208.
 Phosphorus organic compounds, forma-
 tion of, in alcoholic fermentation
 (HARPEN and YOUNG), A., i, 292.
 Phosphorus, estimation of, in bronze,
 brass and similar alloys, in the
 presence of arsenic (SCHÜRMANN),
 A., ii, 545.
 estimation of, in meat (TROWBRIDGE),
 A., ii, 548.
 Phosphoryl chloride. See under Phos-
 phorus.
 PHOTOCHEMISTRY:—
 Light, chemical action of (BAM-
 BERGER and ELGAR), A., i, 267;
 (CIAMICIAN and SILBER), A., i,
 299, 489, 496; (WEIGERT), A.,
 ii, 174, 373.
 circularly-polarised, attempts at
 asymmetric synthesis by means
 of (PADOA), A., ii, 6.
 action of, on dyes (GEBHARD), A.,
 i, 405.
 emission and its excitation
 (LENARD), A., ii, 869.
 production of, by the firefly
 (KASTLE and McDERMOTT), A., ii,
 1088.
 effect of, on the E.M.F. of cells con-
 taining uranous and uranyl sul-
 phates (TITLESTAD), A., ii, 379.
 dispersion of, by potassium vapour
 (BEVAN), A., ii, 914.
 pressure of, on gases (LEBEDEFF),
 A., ii, 472.
 action of, on unsaturated ketones
 (STOBEE and WILSON), T., 1722;
 P., 206; (PRAETORIUS and
 KORN), A., i, 859.
 bleaching of colouring matters by
 (SCHWEZOFF; KÜMMEL), A., ii,
 916.
 ultra-violet, abiotic action of (TAS-
 SILLY and CAMBER), A., ii,
 882.
 comparison of photochemical and
 abiotic action of (CERNOWO-
 DEANU and HENRI), A., ii, 332.
 chemical and biological effects of
 (LOMBARD), A., ii, 197.
 decomposition of alcohols, alde-
 hydes, acids and ketones by
 (BERTHELOT and GAUDECHON),
 A., ii, 814.

XCVIII. ii.

PHOTOCHEMISTRY:—

Light, ultra-violet, conversion of stable
 stereoisomeric ethylene de-
 rivatives into the labile modi-
 fications by (STOERMER), A., i,
 114.
 bactericidal power of (VALLERT),
 A., ii, 332.
 action of, on carbohydrates
 (BIERRY, HENRI, and RANC),
 A., i, 652.
 chemical effects of, on gases
 (BERTHELOT and GAUDECHON),
 A., i, 349; ii, 564; 606.
 action of, on solutions of gold
 salts (SVEDBERG), A., ii, 509.
 action of, on certain medicinal
 preparations and on glucosides,
 alkaloids and phenols (LESURE),
 A., ii, 739.
 paper sensitive to (SCHALL), A.,
 ii, 249.
 action of, on plants (POUGNET),
 A., ii, 993.
 action of, on sugar solutions
 (BERTHELOT and GAUDECHON),
 A., ii, 813.
 effect of, on water (COURMONT,
 NOGIER, and ROCHAIX), A., ii,
 641.
 Solarisation in aqueous solution
 (WINTHER), A., ii, 373.
 Sunlight, organic syntheses by
 (PATKNO and CIEFFI), A., i, 41.
 catalytic action of (NEUBERG), A.,
 ii, 1020.
 Photochemical action (WARBURG), A.,
 ii, 6.
 equilibrium (BAUN), A., ii, 381.
 and electrochemical equilibria
 (SMITS), A., ii, 24.
 formation of formaldehyde in green
 plants (SCHRYVER), A., ii, 334.
 inhibition, nature of (CHAPMAN and
 MACMAHON), T., 849; P., 83.
 phenomena in dye solutions (WEIG-
 ERT), A., ii, 174, 373; (GEBHARD),
 A., ii, 248.
 reactions (WEIGERT), A., ii, 174;
 (BENEATH), A., ii, 813.
 synthesis of carbohydrates and
 quaternary compounds (BERTHE-
 LOT and GAUDECHON), A., i, 543.
 Photo-electric effect of the alkali
 metals in polarised light (PORT),
 A., ii, 90.
 sensitiveness of the alkali metals
 (POHL and FRINGSHEIM), A., ii,
 379, 472.
 of coloured hydrides of alkali
 metals (ELSTER and GEITEL),
 A., ii, 379.

PHOTOCHEMISTRY:—

- Photo-electric effect** of potassium mercury alloys (POHL and PRINGSHEIM), A., ii, 822.
- Photographic images** from silver salts, action of quinones and their sulphonic derivatives on (LUMIERE, LUMIERE, and SEYEWITZ), A., ii, 916.
- Optical activity** of the asymmetric atom (EVANS), A., ii, 6.
- relation of, to position isomerism (COHEN and DUDLEY), A., ii, 1732; P., 209.
- effect of contiguous unsaturated groups on (EDMINSON and HILDITCH), T., 223; P., 10; (HILDITCH), T., 1091; P., 95, 141.
- constants of certain elements (v. WARTENBURG), A., ii, 246.
- of metals, determination of, from polarisation measurements (v. ULJANIN), A., ii, 812.
- and specific gravity of isomeric organic compounds, relation between the (HEYDRICH), A., i, 705.
- inversion**, Walden's (McKENZIE and HUMPHRIES), T., 121; P., 7; (McKENZIE and WAGNER), T., 1016, 2564; P., 85, 325; (McKENZIE and WAGNER), T., 1355; P., 181; (LUTZ), A., i, 230; (FISCHER, SCHIEBLER and GROH), A., i, 522.
- isomerides** (v. OSTROMISLENSKY), A., ii, 247.
- properties and crystallography of organic compounds (BLASS), A., i, 614.
- Optically active compounds**, influence of constitution on the rotatory power of (RUPE), A., i, 398; ii, 470.
- rotation dispersion of (GROSSMANN and LANDAU), A., ii, 1018.
- effect of solvents on the rotation of (PATTERSON and STEVENSON), T., 2110; P., 236.
- containing one asymmetric silicon group (UMLENGER and KIPFING), T., 755; P., 65.
- Optico-chemical constants**, calculation of (REDKOVIC), A., ii, 669.
- Radiation**, homogeneous corpuscular (SADLER), A., ii, 251.
- ultra-red, effect of pressure on the absorption of, by gases (v. BAER), A., ii, 914.
- Rays**, chemical changes produced by different kinds of (NEUBERG), A., ii, 814, 1020.

PHOTOCHEMISTRY:—

- Rays**, corpuscular hypothesis of different kinds of (BRASS), A., ii, 919.
- Rays**, ionisation produced by (WHEELLOCK), A., ii, 1021.
- phosphorescence** produced by (MARSDEN and RUTHERFORD), A., ii, 565.
- radio-chroism of organic substances to (GUILLEMINOT), A., ii, 250.
- Particles**, ionisation produced by air (KLEEMAN), A., ii, 92; (GEIGER), A., ii, 473.
- Particles**, distribution of (RUTHERFORD, GEIGER, and BATEMAN), A., ii, 917.
- scattering of, by matter (GEIGER), A., ii, 472.
- rate of emission of, from uranium, thorium and uranium minerals and products (BROWN, GEIGER and RUTHERFORD), A., ii, 917.
- Rays**, law of absorption of (HAHN and MEITNER), A., ii, 8; (WILSON), A., ii, 175.
- emission and absorption of (CHOUTHER), A., ii, 672; (HAHN), A., ii, 673.
- magnetic line-spectrum of (v. BAER and HAHN), A., ii, 556.
- passage of, through matter (SCHNIGG), A., ii, 7, 378.
- homogeneous, scattering of (CHOUTHER), A., ii, 918.
- range of (BRASS), A., ii, 919.
- phosphorescence produced by (MARSDEN), A., ii, 565.
- radio-chroism of organic substances to (GUILLEMINOT), A., ii, 250.
- of actinium, ionisation of gases by (KLEEMAN), A., ii, 474.
- from radium, absorption of, by solutions and liquids (BOROWSKY), A., ii, 875.
- the scattering of (MADSEN), A., ii, 7.
- from radium-*B*, heterogeneity of (GRAY and WILSON), A., ii, 1022.
- from uraninite, activity of (LLOYD), A., ii, 765.
- Particles**, absorption and reflexion of, by matter (KOVARIK), A., ii, 1021; (KOVARIK and WILSON), A., ii, 1022.
- Rays**, experimental investigation of the nature of (v. SCHWEINLER), A., ii, 376, 766.
- structure of (MEYER), A., ii, 573.
- homogeneity of (SODDY, SODDY, and RUSSELL), A., ii, 474.
- radio-chroism of organic substance to (GUILLEMINOT), A., ii, 250.

PHOTOCHEMISTRY:—

- Positive rays**, emission of, from heated phosphorus compounds (HORTON), A., ii, 176.
- Anode rays**, spectra of (REICHENHEIM), A., ii, 1014.
- Canal rays** of hydrogen, oxygen and nitrogen, positive and negative ions in (WIEN), A., ii, 475.
- Cathode rays**, formation of (DUNOYER), A., ii, 475.
- absorption of, in gases, measurement of, by means of secondary rays (BAERWALD), A., ii, 250.
- of different velocity, absorption of, in helium (ROBINSON), A., ii, 93.
- photoelectric, distribution of, in a vacuum and in different gases (ROBINSON), A., ii, 377.
- ejected by X-rays, ionisation produced in gases by (KLEEMAN), A., ii, 567.
- from secondary Röntgen rays (BEATTY), A., ii, 674.
- influence of, on precious stones (MEYER), A., ii, 9.
- Röntgen rays**, phenomena of transmission of (BARKLA), A., ii, 8.
- ionisation by (BARKLA), A., ii, 920.
- cathode rays ejected by, ionisation produced in gases by the (KLEEMAN), A., ii, 567.
- influence of, on precious stones (MEYER), A., ii, 9.
- radio-chemistry of organic substances to (GUILLERMINOT), A., i, 250.
- secondary homogeneous (CHAPMAN and PIPER), A., ii, 567.
- secondary, from metallic salts (GLASSON), A., ii, 674.
- secondary, production of cathode particles by (BEATTY), A., ii, 675.
- Radioactive constants**, tables of (KOLOWRAT), A., ii, 249; (LAEV), A., ii, 814.
- Radioactive elements**, table of (GREINACHER), A., ii, 569.
- Radioactive emanations**, solubility of, in liquids (BOYLE), A., ii, 677.
- Radioactive minerals** (DOELTER and SIEK; BOYER and WHERRY; WATERS), A., ii, 569.
- Radioactive minerals** of Italy (NASINI and LEVI), A., ii, 1028.
- Radioactive recoil** (RUSE), A., ii, 475; (WERTENSTEIN), A., ii, 476, 816.
- Radioactive substance**, determination of the ratio of mass to weight for a (SOUTHERN), A., ii, 1026.
- Radioactive substances**, influence of temperature on the transformation of (SCHMIDT and CERMACK), A., ii, 918.

PHOTOCHEMISTRY:—

- Radioactive substances**, electric charges acquired in high vacua by (MCLENNAN), A., ii, 678.
- the photographic action of α -particles emitted from (KINOSHITA), A., ii, 375.
- Radioactivity**, apparatus for measuring (SZILARD), A., ii, 7.
- biological (LANCIEN and THOMAS), A., ii, 374.
- of dew (NEGRO), A., ii, 249.
- of the rocks of the Transandinian tunnel (FLETCHER), A., ii, 677.
- of mineral springs. See under Water.
- of the products of the recent eruption of Etna (PIUTTI and MAGLI), A., ii, 1026.
- of the products from the fumaroles of Vesuvius (KERNOT), A., ii, 206.
- Dispersion** in gaseous substances, theory of (NATANSON), A., ii, 170.
- and reflection of liquids, anomalous (MERCZYNO), A., ii, 15.
- and rotation dispersion of naturally active crystals (ROSE), A., ii, 246.
- Reflection** and dispersion of liquids, anomalous (MERCZYNO), A., ii, 15.
- Refraction** of gases; its application to analysis (STUCKERT), A., ii, 245.
- Molecular refraction** of isomerisable unsaturated acids and their salts (HANTZSCH and MEISENBURG), A., ii, 169.
- of thiocyanates and other salts (DIXON and TAYLOR), T., 927; P., 90.
- Refractive index** and volume concentration of a solution, relation between (FOUQUET), A., ii, 393.
- relation between, and density in binary mixtures (SCHWEERS), A., ii, 913.
- of colloids (FREI), A., ii, 365.
- Refractive power** of liquid mixtures, Pulfrich's ratio between volume contraction and (VAN AUDEL), A., ii, 189.
- of substances in dilute solutions (CHENEVEAU), A., ii, 365.
- relative influence of the ketonic and ethenoid linkings on (SMEDLEY), T., 1475; P., 148.
- Refractivity** and volume of dissolved substances, influence of complex formation on the (RIMEACH and WINTERN), A., ii, 810.
- Magnetic double refraction** of aromatic liquids (COTTON and MOUTON), A., ii, 368.

PHOTOCHEMISTRY:—

- Magnetic rotation** of the plane of polarisation in crystalline liquid substances (VIETH), A., ii, 672.
- Mutarotation** and constitution of sugar anilides (IRVINE and McNICOLL), T., 1449; P., 195.
- Rotation** of optically active compounds, effect of solvents on (PATTERSON and STEVENSON), T., 2110; P., 236.
- Rotatory dispersion** (GROSSMANN), A., ii, 563; (GROSSMANN and LANDAU), A., ii, 1017, 1018.

- absorption of larium by** (COLIN and DE RUFFZ), A., ii, 533.
- calcium taken up as silicates by** (MIETH), A., ii, 1105.
- osmotic pressure in** (DIXON and ATKINS), A., ii, 533.
- protective action of sodium for** (OSTERHOUT), A., ii, 62.
- occurrence of arsenic in** (HEADEN), A., ii, 890.
- synthetic production of asparagine in** (PRIAT, SCHNIKOFF and SCHELOFF), A., ii, 835.
- betaines present in** (ENGELAND), A., ii, 885.
- catalase in** (ROMENBERG), A., ii, 992.
- chlorogenic and caffeic acids in** (CHARAUX), A., ii, 991.
- containing coumarin and decomposable glucosides**, action of ultra-violet light on (PORONET), A., ii, 993.
- presence of free hydrocyanic acid in** (RAVENNA and TONEGATTI), A., ii, 844.
- Plants**, assimilation of free atmospheric nitrogen by (MAMELI and POLLACCI), A., ii, 645.
- behaviour of nuclein bases in the dark in** (KIESSEL), A., ii, 800.
- assimilation of pentoses and pentitols by** (BOKORNY), A., ii, 834.
- origin and function of pentosans in** (RAVENNA and MONTANARI), A., ii, 993.
- position at which the nitrogen of nitrates is utilised in** (ACQUA), A., ii, 533.
- behaviour of**, towards lithium salts (RAVENNA and ZAMORANI), A., ii, 235.
- influence of anesthetics and of cold on coumarin-producing** (HECKER), A., ii, 63.
- influence of varying relations between lime and magnesia on the growth of** (BERNADINI and SINISCALCHI), A., ii, 61.
- action of different amounts of copper in the soil on the growth of** (SIMON), A., ii, 64.
- green**, formation of formaldehyde in (SCHRYVER), A., ii, 334.
- action of gaseous formaldehyde on** (GRAFF and v. PORTHIM), A., ii, 335.
- action of vapour on** (MIRANDE), A., ii, 884.
- higher**, action of hydrolysable salts on (GRÉGOIRE), A., ii, 644.
- fermentative cleavage of ammonia in** (KIESSEL), A., ii, 439.
- labiate**, presence of starchose in (PIAULT), A., ii, 330.
- ornamental**, nitrogenous and mineral composition of (HÉBERT and TRUFFAUT), A., ii, 150.
- water**, influence of electricity on the assimilation of carbon dioxide by (KOLTONSKI), A., ii, 333.
- detection of arbutin and methylarbutin in** (BOURQUELOT and FICHTENHOLZ), A., i, 273.
- estimation of chlorophyll in** (MALARSKI and MARCHLEWSKI), A., ii, 362.
- Platinum**, atomic weight of (ARCHBOLD), A., ii, 43.
- incandescence of** (METNIER), A., ii, 15.
- solution of**, in sulphuric acid (DELÉPINE), A., ii, 135.
- red colloidal metallic** (WÖHLER and SPENGLER), A., ii, 1075.
- electromotive behaviour of the oxides of** (GRURE), A., ii, 927.
- Platinum-black**, preparation of (McDELMOTT), A., ii, 804.

- Platinum metals**, magnetic susceptibilities of (FINKER), A., ii, 179.
- Platinum organic compounds** (OSTROMISLENSKY and BERGMANN), A., i, 887.
- Platinum wire**, cleaning of (DE KONINCK), A., ii, 541.
- Substitute for**, in qualitative analysis (KIRBY), A., ii, 445.
- behaviour of**, to hydrogen at high temperatures (v. PIRANI and MEYER), A., ii, 719.
- Plato-pyridine ammine-chloro-sulphite** (OSTROMISLENSKY and BERGMANN), A., i, 887.
- Plato-semitylenediamine chloride** (OSTROMISLENSKY and BERGMANN), A., i, 888.
- Platinum**, colorimetric, estimation of small amounts of (MINGAY), A., ii, 78.
- Plumbogorossite** (HILLEBRAND and WRIGHT), A., ii, 966.
- Plumbonilobite earths** (HAUSER), A., ii, 221.
- Podolite**, probable identity of, with dahllite (SCHALLER), A., ii, 1076.
- Poison**, active principle of a Benin spear (LAIDLAW), A., i, 54.
- of *Adetum Hongkel***, from the French Soudan (PERROT and LEFRANCE), A., ii, 151.
- Poisons**, union of, with cardiac muscle (VERNON), A., ii, 1086.
- and enzymes** (BYWATERS and WALLER), A., ii, 786.
- action of**, on enzymatic processes (SANTERSON), A., ii, 331.
- action of**, on plant respiration (PALADIN), A., ii, 438.
- resistance of animals to**, effect of diet on the (HUNT), A., ii, 736.
- Poisoning**, cobra, and hemolysis (BANG), A., ii, 229.
- by polylenediamine** (JOANNOVICS and PICK), A., ii, 435.
- Polonium**, extraction of (CURIE and DEBIERNE), A., ii, 251.
- radioactivity of**, rate of decay of the (WATERS), A., ii, 569.
- rays of**, decomposition of water by the (BERGWITZ), A., ii, 377.
- Polycarboxylic acids**, unsymmetrical, course of Friedel-Craft's reaction with (KIRPAL), A., i, 504.
- Polychroism** of artificially coloured crystals (GAUBERT), A., ii, 4.
- Polycyclopharic acid** (KUNZ-KRAUSE and MANICKE), A., i, 678.
- Polyfistula** method of London (SAWITSCH), A., ii, 422.
- Polymorphism and isomerism** (CIUSA and PADOA), A., i, 196; (STORCK and WILSON), A., i, 623; (FOCK), A., ii, 23.
- Polypeptides**, synthesis of (FISCHER and LUNJAK), A., i, 136; (ABDERHALDEN and SCHULER), A., i, 304; (ABDERHALDEN and SUWA), A., i, 637; (FISCHER and FIEDLER), A., i, 656; (FISCHER and ROSENBERG), A., i, 657; (ABDERHALDEN and WERNER), A., i, 718; (ABDERHALDEN and HIRSCH), A., i, 720.
- synthetical**, study of enzymes by means of (KOELKER), A., i, 794.
- estimation of**, in urine (HENRIQUES and SØRENSEN), A., ii, 164.
- by the formaldehyde-titration** (HENRIQUES and SØRENSEN), A., ii, 468.
- Polypeptones**, utilisation of, by the tubercle bacillus (KOELKER and HAMMER), A., ii, 737.
- Position isomerism**, relation of, to optical activity (COHEN and DUDLEY), T., 1732; P., 209.
- "Potash salts"**, is their hygroscopic nature an advantage to vegetation? (TACKE), A., ii, 340.
- Potassium**, monotonicity of the molecules of (WENZ), A., ii, 1061.
- fundamental spectrum of** (GOLDSTEIN), A., ii, 669.
- ultra-red line spectrum of** (PASCHEN), A., ii, 1014.
- spark spectrum of** (SCHILLINGER), A., ii, 369.
- vapour**, absorption spectrum of (BEVAN), A., ii, 87.
- dispersion of light by** (BEVAN), A., ii, 914.
- compressibility of**, at different temperatures (PROTZ), A., ii, 187.
- radioactivity of** (ELSTER and GRITEL), A., ii, 378; (HENRIOT), A., ii, 678.
- behaviour of lithium towards** (MÄSSING and TAMMANN), A., ii, 610.
- Potassium alloys**, with mercury, photo-electric effect of (POHL and PRINGSHEIM), A., ii, 922.
- Potassium salts**, native, methods of analysis of (ROEMER), A., ii, 347.
- insulated**, electric charges acquired in high vacua by (McLENNAN), A., ii, 678.
- Potassium arsenosomolybdate** (EPHRAIM and FEIDEL), A., ii, 301.
- bromate**, physiological action of (SANTERSON), A., ii, 431.
- carbonate**, potassium ethyl dipropylmalonate and water, equilibrium in the system (M'DAVID), A., ii, 837.
- chloride**, vapour pressure of aqueous solutions of (KRAUSKOPF), A., ii, 688.

- Potassium chlorate**, action of, on concentrated sulphuric acid (SMITH), P., 124.
- dichromate**, reaction of, with ammonium chloride (FRANKFÖRTER, ROSENTHAL, and MANUEL), A., ii, 292.
- hydroxide**, equilibrium of, with mercuric bromide and chloride (HERZ), A., ii, 945.
- presence of paraffin in, and preparation of a colourless alcoholic solution of (BENGEN), A., ii, 446.
- action of, on calcium phosphate (OESCHNER DE CONINCK), A., ii, 953.
- iodide**, solubility of, in methyl alcohol (CENTNER-SZWER), A., ii, 500.
- and iodine, solubility of, in aqueous-alcoholic solutions (PARSONS and CORLISS), A., ii, 1061.
- and copper sulphate, velocity of reaction between (OLIVERI-MAN-DALA), A., ii, 490.
- tri-iodide**, conductivity and ionisation of (BRAY and MACKAY), A., ii, 320.
- mercuri-iodide**, phenomena observed when, is dissolved in ether and water (MARSH), T., 2297; P., 50.
- zinc iodide** (EPHRAIM and MODEL), A., ii, 351.
- permanganate**, electrolytic production of, from potassium manganate (ASKENASY and KLONOWSKI), A., ii, 413.
- nitrate**, estimation of, in meat, by means of nitron (PAAL and GANGHOFER), A., ii, 453.
- oxyselenophosphate** (EPHRAIM and MAYLER), A., ii, 207.
- silicostungstates**, *d*- and *l*-, dissimilarity in properties of (COFAUX), A., ii, 301.
- amphate**, influence of substances in solution on the velocity of crystallisation and the crystal-habit of (WENZ), A., ii, 23.
- thermal analysis** of the system: potassium fluoride and (KARANDER), A., ii, 33.
- solubility** of, in concentrated aqueous solutions of non-electrolytes (BOX and GAUGE), T., 377; P., 27.
- and sodium sulphates, transformations in mixed crystals (NACKEN), A., ii, 501.
- Potassium cuprictrates** (PICKERING), T., 1337; P., 17.
- Potassium ferrocyanide**, action of, on hydrogen aurichloride, aurous cyanide, finely-divided gold, and gold hydroxide (BEUTEL), A., ii, 722, 723.
- ferro- and ferri-cyanides**, iodometric estimation of (MECKLENBURG), A., ii, 761; (MÜLLER and DITTEL), A., ii, 910.
- methylstannicarbonate** (PFEIFFER, LEHNHARDT, LUFTENSTEINER, PRADÉ, SCHNURMANN, and TRUCKER), A., i, 724.
- thiocyanate**, cryohydrate of (VASILIEFF), A., i, 465.
- thiocyanate and pyridine**, the system (WAGNER and ZERNER), A., ii, 942.
- cobaltous thiocyanate**, absorption spectra of, in organic solvents (v. ZAWIDSKI), A., ii, 562.
- Potassium**, quick detection of small amounts of (BOWSEN), A., ii, 347.
- estimation of (CAVAZZA), A., ii, 459; (BOWSEN), A., ii, 999.
- estimation of, as potassium platinum-chloride (ROHLAND), A., ii, 548.
- estimation of, in silicates (VERWET), A., ii, 74.
- estimation of assimilable, in soils (BIELER-CHATELAIN), A., ii, 453.
- Potential**. See under Electrochemistry.
- Pottery manufacture**, lead silicates in relation to (THORPE and SIMMONDS), T., 2232; P., 254.
- Powders**, smokeless, estimation of nitrogen in (BEEL and JURRISSSEN), A., ii, 240.
- Praseodymium**, action of, on the frog's heart (MINES), A., ii, 794.
- Pratensol** and its triacetyl derivative (POWER and SALWAY), T., 238; P., 20.
- Pratol** from red clover flowers, and its acetyl derivative (POWER and SALWAY), T., 233; P., 20.
- Precious stones**, influence of Röntgen, radium and cathode rays on (MEYER), A., ii, 9.
- Precipitates** "amorphous," proof of their crystalline nature (v. WEIMARN), A., ii, 399.
- small, apparatus for collection of (DIEFOLDER), A., ii, 343.
- Precipitation**, inhibition of, by precipitoids (SPÄT), A., ii, 971.
- reactions, determination of the sensitiveness of (BÜTTNER), A., ii, 185.
- Precipitoids**, inhibition of precipitation by (SPÄT), A., ii, 971.

- Frehnitic acid** (*benzene-1:2:3:5-tetracarboxylic acid*), constitution and esters of (BAMFORD and SIMONSEN), T., 1906; P., 204.
- Pressor bases** in urine (BAIN), A., ii, 528.
- Pressure** uniform in all directions, presumed chemical and physical effects of (SPERZA), A., ii, 773.
- Primverase**, an enzyme in *Primula officinalis* (GORIS and MASCRE), A., ii, 64.
- Primoverin**, a glucoside occurring in *Primula officinalis* (GORIS and MASCRE), A., ii, 64.
- Primula officinalis*, two new glucosides in (GORIS and MASCRE), A., ii, 63.
- Prinulaverin**, a glucoside occurring in *Primula officinalis* (GORIS and MASCRE), A., ii, 64.
- Prismatine** from Waldheim, Saxony (UHLIG), A., ii, 311.
- Proline**, formation of, by hydrolysis of gelatin (FISCHER and BOEHNER), A., i, 345.
- L*-Propyl-*D*- and *L*-phenylalanines, and the copper salt (FISCHER and LUTIAK), A., i, 136.
- trans-cyclo*Propane-1:2:3-tricarboxylic acid, ethyl ester (DARAPSKY), A., i, 437.
- cyclo*Propane-1-carboxylic acid, 1-cyano-ethyl ester (MITCHELL and THORPE), T., 1002.
- Propenylsuccinic acid** and its calcium salt (FICHTER and PROBST), A., i, 217.
- Prophylaxis** in malaria (GRAZIANI), A., ii, 982.
- Propionamidophosphoryl**, α -dichloro-dichloride (STEINKOFF, BOHRMANN, GRÜNUPF, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 308.
- Propionanilide**, *p*-nitro- (TINGLE and BURKE), A., i, 21.
- Propionic acid**, sodium salt, compound of, with acetic anhydride (TSAKALOTOS), A., i, 458.
- Propionic acid**, α -bromo-, interaction of, and its sodium salt, with silver salts in aqueous solution (SEETER), T., 346; P., 23.
- L*, and its inactive form (RAMBERG), A., i, 4.
- di*thio-, methyl ester (HOUREN and SCHULTZE), A., i, 711.
- Propioniminoethyl ether** (MATSUI), A., i, 696.
- γ -Propionyl-*n*-butyric acid, semicarbazone and *p*-nitrophenylhydrazones (BLAISE and KOEHLER), A., i, 561.
- Propionylethanol**, 4- α - and β -amino-, and their hydrochlorides (FARBEN-FABRIKEN VORM. F. BAYER & Co.), A., i, 314.
- 2-Propionyl-2-ethylcyclopentanone** (BLAISE and KOEHLER), A., i, 627.
- 5-Propionyl-*n*-heptonic acid**, and its derivatives (BLAISE and KOEHLER), A., i, 627.
- 2-Propionylcyclohexanone**, derivatives of (BLAISE and KOEHLER), A., i, 627.
- 5-Propionyl-*n*-hexonic acid**, and its semicarbazone (BLAISE and KOEHLER), A., i, 627.
- Propionyl-leucinamide**, bromo- (BERGELL and v. WULFING), A., i, 365.
- d*-Propionyl-*L*-leucyl-*D*-isoleucine, α -bromo- (ABDERHALDEN and HIRSCH), A., i, 720.
- 2-Propionyl-2-methylcyclopentanone** (BLAISE and KOEHLER), A., i, 627.
- 2-Propionylcyclopentanone**, salts and derivatives of (BLAISE and KOEHLER), A., i, 627.
- Propionylserine**, α -bromo- (FISCHER and ROESNER), A., i, 658.
- Propionylveratrole**, α -amino- (FARBEN-FABRIKEN VORM. F. BAYER & Co.), A., i, 314.
- o*-, *m*-, and *p*-Propoxybenzoic acids, menthyl esters of (COHEN and DUDLEY), T., 1742.
- o*- and *p*-isopropoxybenzoic acids, menthyl esters of (COHEN and DUDLEY), T., 1743.
- Propyl alcohol**, specific gravity of mixtures of water and (DOROSCHESKY and ROSCHDESTVENSKY), A., i, 85.
- α -isopropyl- γ -acetylbutyric acid, and its semicarbazone (SCHIMMEL & Co.), A., i, 758.
- n*- and iso-Propylammonium, tri-dichlorides and bromides (GUTBIER and RIES), A., i, 97.
- platinibromide (GUTBIER and BAURIEDL), A., i, 12.
- Propylbenzene**, γ -iodo- (v. BBAUN), A., i, 844.
- iso-Propylbenzene, *p*-iodo-, diiododichloride and other derivatives (SCHREINER), A., i, 468.
- n*-Propylbenzocycloheptadienone (THIELE and WEITZ), A., i, 854.
- p*-iso-Propylbenzylidene-*p*-aminobenzoic acid (MANCHOT and FURLONG), A., i, 34.
- α -iso-Propylbutyric acid, β -hydroxy-, synthesis of, and ethyl ester and salts (MATZUREVITSCH), A., i, 89.
- 1-Propylcitronellol** (AUSTERWEIL and COCHIN), A., i, 572.

- 2-Propyldihydroisoindole**, and its derivatives (SCHOLTZ and WOLFRUM), A., i, 773.
- isoPropyldiphenyl-1:1'-2'-tricarboxylic acid**, 3-hydroxy- (BUCHER), A., i, 239.
- Propylene**, preparation of (SENDERENS), A., i, 649.
- oxide, and the corresponding hydroxy-chloroacetate (PRIESCHAEFF), A., i, 86.
- Propylenediammonium**, iridi-chloride and bromide (GUTHRIE and RIKSS), A., i, 98.
- platinibromide (GUTHRIE and BAURIEDL), A., i, 13.
- Propyleneguanidine**. See 2-Imino-4-methyltetrahydroglyoxaline.
- d*- and *l*-**isoPropylheptanonolide** (BARBIER and GRIGNARD), A., i, 555.
- Propylenediacetate** (WEGSCHEIDER and SPÄTH), A., i, 155.
- isoPropylenediacetoacetaldehyde**, and its copper salt (COUTURIER), A., i, 299.
- isoPropylenediacetone**. See Mesityl oxide.
- Propylenedibishydrazobenzene** (RASNOW and BAUMANN), A., i, 79.
- 1-isoPropylcyclopentan-1-ol** (MEERWEIN and UNKEL), A., i, 857.
- isoPropylisophthalic acid**, synthesis of (BARCELLINI), A., i, 744.
- p*-**isoPropylstyryl nonyl ketone** (SCHOLTZ and MEYER), A., i, 562.
- Propylsuccinic acid**, anilide, anil, diamide, dihydrazide, and dibenzylidene derivative of (LOCQUIN), A., i, 10.
- Propyltheophylline**, chlorohydroxy- (CHEMISCHE WERKE VORM. DR. H. BYK), A., i, 766.
- Propylurethane**, and its nitroso-derivative (NIEDLINGER, ACREE, and HEATH), A., i, 342.
- Protagon**, comparison between the properties of, and those of a mixture of phosphatides and cerebrosidea (CRAMER), A., i, 296.
- non-existence of, in the brain (ROSENHEIM and TEEB), A., i, 529.
- Protamines** (KOSSEL), A., i, 908.
- action of proteolytic enzymes on (TAKEMURA), A., i, 82.
- Protein**, parenteral administration of (V. KOROBY), A., ii, 1084.
- action of alkalis on (KOSSEL and WEISS), A., i, 791.
- content in the human organs (MAGNUS-LEVY), A., ii, 426.
- in the pancreatic juice (WECHSLER), A., i, 527.
- cleavage in the stomach (SCHREINERT), A., i, 322.
- Protein**, formation in ripening seeds (SCHULZE and WINTERSTEIN), A., ii, 644.
- in plants, the part played by oxygen in the formation of (ZALESSKI), A., ii, 149.
- cleavage products, value of, in metabolism (ABDERHALDEN and FRANK), A., ii, 322.
- (ABDERHALDEN and GLAMSER; ABDERHALDEN and MANOLIU), A., ii, 521; ABDERHALDEN and RONA), A., ii, 877; (ABDERHALDEN and SUWA), A., ii, 975.
- of the partial hydrolysis of (ABDERHALDEN and SUWA), A., i, 528.
- coagulation, the relation between muscle rigor and (ROSSI), A., ii, 730.
- lysine-free, putrefaction of (ACREMANN), A., i, 288.
- the phosphorylation of (NEBERG and POLLAK), A., i, 610.
- of Bence-Jones, so-called (CHRISTIAN, GÉRARD, and THOMAS), A., ii, 733; (WILLIAMS), A., ii, 981.
- is it produced from osseo-albumoid? (ROSENBLUM), A., ii, 731.
- resorption of the (BOCHARDT and LIPPMAN), A., ii, 521.
- solutions, behaviour of, with acetone (WEYL), A., i, 287; ii, 468.
- influence of urea on the internal friction and conductivity of (MORUZZI), A., i, 791.
- metabolism. See under Metabolism.
- combinations, determination of iodine in (RIGGS), A., ii, 650.
- Proteins**, general chemistry of (MICHAELIS and RONA), A., i, 646, 905.
- adsorption of (BLITZ and STEINER), A., i, 209.
- the refractive indices of solutions of (ROBERTSON), A., i, 526, 793.
- heat coagulation of (CHICK and MARTIN), A., i, 597.
- differentiation of, by the precipitation reaction (WELSH and CHAMMAN), A., ii, 975.
- electrochemistry of (ROBERTSON), A., ii, 679, 939.
- catalytic action of (DAKIN), A., i, 101.
- hydrolysis of (ABDERHALDEN), A., i, 447, 792.
- by acids, the quantity of amino-acids yielded by (OSBORN and BRIDGES), A., i, 447.
- by sulphuric acid (SKRAFT and KRAUSE), A., i, 447.
- by hydrogen chloride (FRANKE), A., i, 289.

- Proteins, partial hydrolysis of (ABDERHALDEN), A., i, 211; (ABDERHALDEN and FUNK), A., i, 320; (LRYENE, VAN SLYKE, and BIRCHARD), A., i, 794.
- synthesis and cleavage of, in the animal organism (ABDERHALDEN and LONDON), A., ii, 425.
- difference in nutritive value of, in relation to their composition (ZISTERER; VOIT and ZISTERER), A., ii, 425.
- protective action of, on enzymes (ROSENTHALER), A., i, 600.
- compounds of, with inorganic haloid salts (SIMON), A., i, 527.
- of milk, biological differentiation of milk and (KOLLMAYER), A., ii, 633.
- precipitation of, by salts, of heavy metals, calorimetric investigation of the (GAYDA), A., i, 527.
- iodo- (NEUBERG), A., i, 704.
- Proteins, colour reactions of (REICHARD), A., ii, 363; (ARNOLD), A., ii, 560.
- analysis of (ETARD and VILA), A., i, 598; (OSBORNE and JONES), A., i, 598; ii, 763.
- estimation of, in milk and blood (WEYL), A., i, 287.
- estimation of peptide compounds in, and in their cleavage products (HENRIQUES and GJALDBAK), A., ii, 764.
- See also Serum proteins.
- Proteolysis, gastric (CHOAY), A., ii, 516.
- Prothrombin (HOWELL), A., i, 793.
- Protocatechualdehyde, semicarbazone of (KNÖFFER), A., i, 433.
- chloro-, and its derivative with ethyl chlorocarbonate (WEISSE), A., i, 853.
- Protocatechylproteins, pharmacological action of (MARSHALL), A., ii, 639.
- Protoplasm and blood, neutrality equilibrium in (HENDERSON), A., ii, 139.
- Fruites, occurrence of, in plants (ARMSTRONG; ARMSTRONG and HORTON), P., 334.
- Prunetin, and its derivatives (FINNEMORE), A., ii, 1102.
- Prunetol, and its derivatives (FINNEMORE), A., 1002.
- Fruitrin (FINNEMORE), A., ii, 1103.
- Prunol, and its sodium derivative (POWER and MOORE), T., 1104; P., 124.
- Prunus, examination of the bark of a species of (FINNEMORE), A., ii, 1102.
- Prunus serotina (black cherry), the constituents of the leaves of (POWER and MOORE), T., 1099; P., 124.
- Pseudocinchona africana* (Rubiaceae), hydrolysis of new alkaloid from (FOURNEAU), A., i, 501.
- Pseudonepheline, from Capo di Bove, near Rome (ZAMBONINI), A., ii, 1078.
- Ptyalin concentration, relation of, to diet and to the rate of secretion of saliva (CARLSON and CRITTENDEN), A., ii, 516.
- Pucherite, from West Australia (GRIF-FITUS), A., ii, 47.
- Pukates, alkaloids of the (ASTON), T., 1381; P., 11.
- Pukateina, and its salts (ASTON), T., 1382; P., 11.
- Pulegenic acid, methyl ester, reduction of (RUPE and BÜRGIN), A., i, 378.
- Pulegone, conversion of, into menthenes (AUWERS), A., i, 122.
- oxime, hydroxylamineoxime, nitrosohydroxylamine and semicarbazone (CRISMANO), A., i, 183.
- Pulegyl alcohol, and its derivatives (RUPE and BÜRGIN), A., i, 378.
- Pump, Toepler (STEELE), A., ii, 602; (v. ANTROPOFF), A., ii, 947.
- Pumpkin. See *Cucurbita Pepo*.

- Purgic acid, hydrolysis of (VUTOČEK), A., i, 274.
- Purine formation, origin of (MAREŠ), A., ii, 973.
- metabolism. See Metabolism.
- Purine bases, of the bone-marrow (THAR), A., ii, 141.
- in cancerous tumours (SAIKI), A., ii, 146.
- estimation of, in urine (KENNAWAY), A., ii, 83.
- Purine enzymes, in the rat (ROHDÉ and JONES), A., ii, 430.
- Purpuric acid (HANTZSCH and ROBISON), A., i, 200.
- Putrefaction bases, production of (ELLINGER), A., i, 447.
- from the decomposition of soybeans (*Glycine hispida*) (YOSHIMURA), A., ii, 1103.
- Pyramidone, titration of (LEMAIRE), A., ii, 909.
- Pyranthrene (SCHOLL and POTTSCHWALSCHEG), A., i, 272.
- Pyranthroque (SCHOLL and SEER), A., i, 271.
- Pyrazines, substituted, and their salts, absorption spectra of (TUTIN and CATON), T., 2524; P., 245.
- Pyraziscoumarazone, and 4-bromopyraziscoumarazone (MICHAELIS and ZIESEL), A., i, 513.

- Pyrazole**, new preparation of (OLIVERI-MANDALA), A., i, 433.
- Pyrazolines**, influence of constitution on the conversion of phenylhydrazones of unsaturated compounds into (AUWERS and Voss), A., i, 70.
- Pyrazoquinazoline**, 7-chloro-, and 7-hydroxy- (MICHAELIS and ZIESEL), A., i, 513.
- Pyrene**, formation of, from thehaine (FREUND), A., i, 631.
structure of (LANGSTEIN), A., i, 726.
- Pyrene acid**, α - and β -methyl hydrogen esters of (LANGSTEIN), A., i, 726.
- Pyridino**, absorption spectra of the vapours of, and its derivatives (PURVIS), T., 692; P., 45.
equilibrium in the system, and mercuric chloride (MOBRIDGE), A., ii, 401.
and potassium thiocyanate, the system (WAGNER and ZERNER), A., ii, 942.
action of sulphites on (REITZENSTEIN and BRUNING), A., i, 876.
action of, on 1:3-dichloro-4:6-dinitrobenzene (ZINCKE and WEISPFENNING), A., i, 585.
action of, on 2-chloro-3:5-dinitrobenzoic acid (ZINCKE), A., i, 556.
behaviour of, in goats and pigs (TOTANI and HOSHIAI), A., ii, 881.
derivatives, formation of, from the condensation products of aldehydes with ketones (SCHOLTZ and MEYER), A., i, 561.
hydrate (DE CONINCK), A., i, 188.
- Pyridine bases**, action of 1-chloro-2:4-dinitrobenzene on (REITZENSTEIN and STAMM), A., i, 283.
- Pyridinium iridi-chloride** and bromido (GUTHRIE and RIESS), A., i, 98.
molybdenum cyanide (ROSENHEIM, GARBUNKEL, and KOHN), A., i, 102.
stannic salts (PFEIFFER, FRIEDMANN, and REKATE), A., i, 877.
- α -Pyridinylacrylic acid**, derivatives of (PFEIFFER, LANGENBURG, and BRENCWIG), A., i, 878.
- Pyridinylmaleic acid**, derivatives of (PFEIFFER, LANGENBURG, and BRENCWIG), A., i, 878.
- Pyrimidine derivatives**, metabolism of (MENDEL and MYERS), A., ii, 521.
containing mercury, preparation of (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 804.
- Pyrimidines** (JOHNSON), A., i, 69; (WHEELER, MCFARLAND, and STOREY), A., i, 188.
- 6-Pyrimidone**, 2:4-diamino-5-succinyl-amino- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 79.
- Pyrites**, analysis of (VILSTRUP), A., ii, 458.
estimation of sulphur in (ZARNETMAYER), A., ii, 802.
estimation of sulphuric acid and sulphur in (HUYBRECHTS), A., ii, 544.
- α -Pyrocresol**, constitution of (ZMER-ZLIKAR), A., i, 763.
- Pyrogallol dimethyl ether**, as a reagent for chromic acid, ferric salts, and nitrites (MEYERFELD), A., ii, 901.
- Pyrola rotundifolia*, glucoside of (FICHTENHOLZ), A., ii, 889.
- Pyrrrole**, absorption spectrum of (PRIVIA), T., 1648; P., 201.
derivatives, synthesis of (PILOTV), A., i, 277.
- Pyrrolidinocarboxylic acid**, preparation of calcium salt (ABDERHALDEN and KAUTZSCH), A., i, 280.
- Pyrrolidone derivatives**, amino-, from mesityl oxide (KOHN and BEN), A., i, 136.
- Pyrrolidonecarboxylic chloride** (ABDERHALDEN and SUWA), A., i, 687.
- Pyrrolidonecarboxylic acid**, formation of (ABDERHALDEN and KAUTZSCH), A., i, 768.
- Pyrrolidonylglycine**, and its ethyl ester and copper salt (ABDERHALDEN and SUWA), A., i, 637.
- Pyrrrophyllin**, and its salts (WILLSTÄTTER and FRITZSCHE), A., i, 128.
- Pyrrporphyrin**, and its ester and salts (WILLSTÄTTER and FRITZSCHE), A., i, 129.
- Pyrryl ethyl ketone**, phenylhydrazone (ODDO), A., i, 426.
- 2-Pyrryl propyl ketone**, and its phenylhydrazone (ODDO), A., i, 426.
- Pyrrvaldehyde-bis-somicarbazone** (RITZ and KESLER), A., i, 94.
- Pyruvic acid**, preparation of (WOHL and MAAG), A., i, 606.

Q.

- Quartz**, crushed, action of, on nitrate solutions (PATTEN), A., ii, 950.
- Quercitol pentaphosphate** (CONTARIS), A., i, 810.
- Quercitrin**, and its trisodium derivative (MOORE), P., 182.
- Quercyrite** (LACROIX), A., ii, 720.
- Quinazolinones** (BOGERT and GOSWAMI), A., i, 283; (BOGERT, AMEND, and CHAMBERS), A., i, 893.

- 4-Quinoxalones-2-carboxylic acid (4-hydroxyquinoxaline-2-carboxylic acid) and its ammonium salt and ethyl ester (BOGERT and GORTNER), A., i, 234.
- Quinhydrone, from chloranil and aromatic hydrocarbons (HAAKE), A., i, 43.
- Quinine, constants of the first and second dissociations of (BARRATT), A., i, 336.
action of chlorine and ammonia on (COMANDUCCI), A., i, 581.
effect of, on resistance to infection (GRAZIANI), A., ii, 982.
influence of, on trypanosome infection (MORONROTH and HALBERSTADTER), A., ii, 881.
hydrochloride, rotatory power of (ANDRÉ and LEULIER), A., i, 581.
- β -Quinine ethiodide, action of Grignard's reagent on (FREUND and MAYER), A., i, 132.
- Quinine salts, tests for purity of (TUTIN), A., ii, 1124.
- Quinol monomethyl ether, benzoyl-amino-, and nitro-, benzoste of (KAUFFMANN and FRITZ), A., i, 377.
triphenylmethyl ether (SCHMIDLIN, WOHL, and THOMMEN), A., i, 377.
dichloroacetate (ABERHALDEN and KAUTZSCH), A., i, 254.
- Quinol, 2-5-dinitro-, as an indicator for measuring hydrogen ion concentration (HENDERSON and FORBES), A., ii, 541.
- Quinolbenzoin, and its chloride (v. BAERYER, AICKELIN, DIEHL, HALLENLEBEN, and HESS), A., i, 252.
its salts and dimethyl ether (KEHRMANN and SILZER), A., i, 408.
- Quinoline, absorption spectra of, as vapour liquid and in solution (PURVIS), T., 1035; P., 113.
p-hydroxyazo-derivatives of (FOX), T., 1337; P., 137.
sulphosalicylate (PRUNIER), A., i, 585.
- Quinoline, 3-acetylamino-, 3-amino-, and its coloured salts, 2-chloro-3-amino-, and 3-hydroxy-, and its sulphate (MILLS and WATSON), T., 745; P., 56.
- 5-7-dibromo-8-amino-, acetyl and benzoyl derivatives of, and 5-7-dibromo-8-nitro-, and its platinum chloride (KUNCKELL), A., i, 507.
8-hydroxy-, metallic salts of (FOX), T., 1119; P., 134.
5-hydroxy- (EDINGER and BÜHLER), A., i, 64.
- Quinolines, tricyclic (BOESCHER, SCHMIDT, TIETKE, and ROTTSIEPER), A., i, 880.
- iso*Quinoline bases, synthesis of (PICTET and GAMS), A., i, 773.
derivatives (PYMAN), T., 264; P., 21; (PYMAN and RYNNOLDS), T., 1320; P., 180.
- Quinolineazo-8-hydroxyquinoline, and its sodium salt and hydrochlorides (FOX), T., 1345.
- Quinoline-3-azo-8-naphthol (MILLS and WATSON), T., 753; P., 56.
- Quinolineazophenotole (FOX), T., 1347.
- Quinolineazophenol, and its hydrochlorides and acetate (FOX), T., 1346.
- Quinoline-3-carboxamide, and 2-chloro- (MILLS and WATSON), T., 745; P., 56.
- Quinoline-6-carboxylic acid, ethyl and diethylaminoethyl esters, hydrochlorides (EINHORN and FRIBELMANN), A., i, 134.
- Quinolinsiodoacetamide (EINHORN and GÖTTLER), A., i, 134.
- Quinoline-6-mercaptan-8-carboxylic acid, benzoyl derivative (EDINGER and BÜHLER), A., i, 64.
- Quinolins-red (VONGERICHTEN and KRAUTZ), A., i, 201.
- Quinolinium stannic salts (PFEIFFER, FRIEDMANN, and REKATE), A., i, 377.
- iridi-chloride and bromide (GUTHRIE and RIESS), A., i, 98.
- 4-Quinolone, 2,3-dihydroxy-, and its benzoyl derivative (HELLER and TISCHNER), A., i, 65.
- Quinolphthalcin methyl ester, salts of (KEHRMANN and SILZER), A., i, 407.
- Quinolquinone-chloro- and dichloroimide (KNORR), A., i, 324.
- Quinolyl *iso*quinolyl ketone and its oxime (VONGERICHTEN and KRAUTZ), A., i, 201.
- Quinone $C_{10}H_6O_2$ (two isomerides) from oxidation of diethylantraceneindandione and diethylphenanthreneindandione respectively (FREUND and FLEISCHER), A., i, 491.
- $C_{12}H_{10}O_4$ from oxidation of diethylreteneindandione (FREUND and FLEISCHER), A., i, 492.
formation of a keten-like (LEUCHS and THEOPHILUSCU), A., i, 395.
- p*-Quinone. See *p*-Benzquinone.
- Quinones, action of triphenylmethyl on (SCHMIDLIN, WOHL, and THOMMEN), A., i, 377.
compounds of, with esters of aminoacids (FISCHER and SCHRADER), A., i, 270.

Quinones, additive compounds of, with acids and phenols (MEYER), A., i, 179.
and their sulphonic derivatives, action of, on photographic images (LUMIERE; LUMIERE and SEWETZ), A., ii, 916.
estimation of (WILLSTÄTTER and MAJIMA), A., ii, 553.
Quinonoid compounds (WILLSTÄTTER and MAJIMA), A., i, 748; ii, 553.

B.

Rabbit, purine enzymes of (MITCHELL), A., ii, 731.
Racemic aldehydes, attempted resolution of (WOOLTON), T., 405; P., 43.
compounds, existence of, in solution (DUNSTAN and THOLE), T., 1249; P., 146.
triboluminescence of (v. OSTROMISSENSKY), A., ii, 1019.
liquid (LADENBURG), A., i, 686; (LADENBURG and SOBERG), A., i, 769.
Racemisation of optically active hydantoin derivatives (DAKIN), A., i, 590.
Racemism, partial (DITTLI), A., i, 188.
Radiation and Rays. See under Photochemistry.
Radioactivity. See under Photochemistry.
Radio-lead (HERCHFINKEL), A., ii, 817.
Radium content of basalt (STRETT), A., ii, 1025.
content of rocks (BÜCHNER), A., ii, 1025.
content of Cambridge waters and of varieties of charcoal (SATTERLEY), A., ii, 1025.
ratio of, to uranium in minerals (SODDY and PIBRET), A., ii, 922.
in the atmosphere (KURZ), A., ii, 476.
disintegration products of, in the atmosphere (PACINI), A., ii, 374.
metallic (CURIE and DEBIÈRE), A., ii, 816.
attempts to prepare (EHLER), A., ii, 1024.
relation between uranium and (SODDY), A., ii, 10, 921.
the half-life period of (GRAY and RAMSAY), T., 185; P., 25.
the disengagement of heat in a mixture of, with a phosphorescent salt (DUANE), A., ii, 816.
production of helium by (RUTHERFORD and BOLWOOD), A., ii, 175; (DEWAR), A., ii, 376.

Radium, energy of the rays of (DUANE), A., ii, 815.
 β -rays of (KOLOWRAT), A., ii, 815.
the scattering of β -rays of (MAJIMA), A., ii, 7.
absorption of β -rays from, by solutions and liquids (BORODOWSKY), A., ii, 375.
disengagement of emanation from salts of (KOLOWRAT), A., ii, 81.
emanation, atomic weight of (DEBIÈRE), A., ii, 675.
influence of, on equilibrium in a gaseous system (USHER), T., 368, 1193; P., 20, 133.
density of (RAMSAY and GRAY), A., ii, 767.
amount of, in the atmosphere, and its variation with the weather (SATTERLEY), A., ii, 676.
measurement of (DUANE and LABORDE), A., ii, 678.
measurement of the constant of (CURIE), A., ii, 374.
French and German units of measurement for (JABOIN and BEATDOIN), A., ii, 675.
ionisation of air by (DE BROGLIE), A., ii, 579.
absorption of, by coconut charcoal (SATTERLEY), A., ii, 921.
action of, on colloids (JONISSEN and WOUTSTRA), A., ii, 1024.
physiological behaviour of (LASZ), A., ii, 431.
action of, on the development of animal eggs (HERTWIG), A., ii, 983.
detection of, in urine (LAQUEZ), A., ii, 58.
rays, influence of, on precious stones (MEYER), A., ii, 9.
influence of, on the coloration of saundin, zircon, and quartz (BRUNS), A., ii, 9.
Radium, estimation of (LLOYD), A., ii, 568.
by measurement of the emanation (CURIE), A., ii, 476.
Radium bromide, action of, on the skin of the rabbit's ear (BARRATI), A., ii, 983.
sulphate, slow precipitation of (KOLOWRAT), A., ii, 767.
Radium salts, disengagement of emanation from (KOLOWRAT), A., ii, 1023.
Radium-A ions, method for determination of the constants of (SALPETER), A., ii, 220.
Radium-B, deflexion by an electrostatic field of, on recoil from radium-A (RUSS and MAKOWER), A., ii, 1029.

- Radium-*B*, deflexion by a magnetic field of, on recoil from radium-*A* (MAKOWER and EVANS), A., ii, 1023.
- Radium-*C* and -*B*, recoil of (MAKOWER and REISS), A., ii, 91.
- Radium-*D* and its transformation products (ANTONOFF), A., ii, 568.
- Radium-*E*, heterogeneity of β -rays from (GRAY and WILSON), A., ii, 1022.
- Raffinose, influence of salts on the rotatory power of (WASHBURN), A., i, 300.
- Rain-water. See under Water.
- Raspberries, occurrence of formic acid in (RÖHRIG), A., ii, 235.
- Rats, resistance of, to thyroidectomy, and morphine poisoning (OLDS), A., ii, 797.
- Redalose (WEYL), A., i, 792.
- Reductase in liver and kidney (HARRIS), A., ii, 324, 730.
- Reduction of metallic oxides, initial temperatures of (FAY, SEEKER, LANE, and FERGUSON), A., ii, 711.
- of the nitro-group by hydrogen sulphide (GOLDSCHMIDT and LARSEN), A., ii, 282.
- Reductodehydrochloric acid and its dioxime (SCHENCK), A., i, 10.
- Refractivity: See under Photochemistry.
- Renal calculi, insoluble calcium salts in (MACKARELL, MOORE, and THOMAS), A., ii, 732.
- Rennet in *Vasconcellea quercifolia* (GERBER), A., ii, 64.
- influence of acids on the loss of activity of, caused by shaking (SCHMIDT-NIELSEN and SCHMIDT-NIELSEN), A., i, 801.
- Rennin (*chymosin*), identity of, with pepsin (van DAM), A., i, 290; (RAKOCZY), A., i, 801; (SAWITSCH), A., ii, 876.
- and pepsin, filtration of (FUNK and NIEMANN), A., i, 801.
- and pepsin, activities of, in dogs and calves (HAMMARSTEN), A., ii, 876.
- Resazine, tribromo- (HEIDUSCHKA and SCHELLER), A., i, 397.
- Resin acids, of the Conifere (EASTFIELD and BEE), T., 1028; P., 7.
- Resins, estimation of, in turpentine oils (NICOLARDOT and CRÉMENT), A., ii, 460.
- Resotyclopharol (KUNZ-KRAUSE and MANICKE), A., i, 678.
- Resorcinol, condensation of *sal*aldehyde with (POPE and HOWARD), T., 972; P., 88.
- condensation of benzaldehyde with (POPE and HOWARD), T., 78.
- Resorcinol, bisazo-, and trisazo-derivatives of (ORNDORFF and RAY), A., i, 597.
- dichloroacetate (ABDERHALDEN and KAUTZSCH), A., i, 254.
- detection of (VOICY-BOUCHER and GIRARD), A., ii, 162.
- Resorcinol, 2:6-*d*-bromo-4-acetylaminio-, diacetate of, 2:6-*d*-bromo-4-amino-, and its hydrochloride, and 2:6-*d*-bromo-4-nitro-, and its ammonium salt (RAIFORD and HEYL), A., i, 730.
- 6-nitro-4-acetylaminio-, 6-nitro-4-amino-, 4:6-diacetylaminio-, and 4:6-*d*-nitro-, and their derivatives (HELLER and SOURLIS), A., i, 749.
- Resorcyllaldehyde, hydrobromide (GOMBERG and CONE), A., i, 872.
- semicarbazone (KNÖPPER), A., i, 433.
- Resorption, processes of, in the alimentary tract (TRAUBE), A., ii, 397.
- Respiration apparatus, for clinical work (GRAFE), A., ii, 422.
- of bees (PARHON), A., ii, 513.
- of plants. See Plant respiration.
- of various organs (COHNHEIM; COHNHEIM and PLETNEFF), A., ii, 1079.
- influence of various agents on (HILL, MACKENZIE, ROWLANDS, TWORT, and WALKER), A., ii, 1079.
- experiments, influence of the exact estimation of the tension of water vapour on (MURSCHHAUSER), A., ii, 784.
- influence of increase in alveolar tension of oxygen on (HOUGH), A., ii, 511.
- at high altitudes (DOUGLAS), A., ii, 784.
- failure of, after intense pain (HENDERSON), A., ii, 227.
- Respiration calorimeter, control tests of a (BENEDICT, RICHE, and ENNKE), A., ii, 511.
- Respiratory quotients after exclusion of the abdominal organs (PORGES; PORGES and SALOMON), A., ii, 785.
- Respiratory centre, action of certain substances on the (LOEVENHAFT and GROVE), A., ii, 724.
- Retene, constitution of (BUCHER), A., i, 239; (LUX), A., i, 239, 745.
- Retenequinone *hemiperchlorate* (HOFMANN, METZLER and LECHER), A., i, 187.
- tribromo-, and its derivatives, and tribromonitro- (HEIDUSCHKA and SCHELLER), A., i, 397.
- Retenequinoneaminoguanidine, and tribromo- and their hydrochlorides (HEIDUSCHKA and SCHELLER), A., i, 397.

- iso*Rhamnetin, in red clover flowers (POWELL and SALWAY), T., 244; P., 20.
- Rhein**, and its potassium derivative and propionate (OESTERLE and RIAT), A., i, 126.
- Rhizome** of *Cimicifuga racemosa*, chemical examination of (FINNEMORE), A., ii, 801.
- Rhodanic acids**, substituted, and their condensation with aldehydes (KALUZA), A., i, 130; (ANDREASCH), A., i, 694.
- Rhodanin-glycylglycine** (ANDREASCH), A., i, 695.
- α -**Rhodaninpropionic acid** (ANDREASCH), A., i, 695.
- Rhodanines**, preparation of (HOLMBERG), A., i, 361.
- substituted, and their condensation products with aldehydes (ASTULICH), A., i, 764.
- α - and β -**Rhodochexonic acids**, and their lactones, phenylhydrazides, and salts (KRAUTZ), A., i, 224.
- α - and β -**Rhodochexose**, and their hydrazones and osazones (KRAUTZ), A., i, 224.
- Rhodose**, configuration of (VOTOČEK), A., i, 223.
- iso***Rhodose**, composition of crude, and its osazone, *p*-bromophenylsazone, and *p*-bromophenylhydrazone (VOTOČEK), A., i, 274.
- Rhodizite**, in the pegmatites of Madagascar (LACROIX), A., ii, 46.
- Rhodophyllin**, dimethyl ester and potassium salt (WILLSTÄTTER and FRITZSCHE), A., i, 128.
- Rhodoporphyrin**, dimethyl ester and compounds with zinc and iron acetates (WILLSTÄTTER and FRITZSCHE), A., i, 129.
- Rhonite**, from Puy de Barneire at Saint-Sandoux (LACROIX), A., ii, 49.
- Rhus Cotinus*, volatile oil of (PERRIER and FOUCHET), A., i, 54.
- d*-**Ribose**, in the pancreas (JACOBS and LEVENE), A., ii, 729.
- Ricinoleic acid**, methyl ester, ozonide of (HALLER and BROCHET), A., i, 216.
- Ring**, four-carbon, instance of the stability of the (CAMPELL and THORPE), T., 2418; P., 296.
- six-membered, formation of, by means of the imino-group (THOLE and THORPE), P., 295.
- Ring formation** in ketonic acids (BLAISZ and KORNBERG), A., i, 626.
- Rivas' test**, is there caramelisation in? (HORN), A., ii, 668.
- Rivotite** (LACROIX), A., ii, 782.
- Robinia pseudacacia*, oil of (ELZE), A., i, 678.
- Rocks**, radium content of (BECHEMER), A., ii, 1025.
- calcareous and dolomitic, amount of thorium in (JOLY), A., ii, 723.
- dyke, in Northumberland (HESLOP and SMYTHIE), A., ii, 313.
- Rock analyses**, and river-water analyses correlation of (SHRETON), P., 110.
- Röntgen rays**. See under Photochemistry.
- Rongalite** (sodium formaldehydesulph. oxybate), and salts of amines (BENZ and MARX), A., i, 728.
- Roots**, selective absorption of ions by (PANTANELLI and SELLA), A., ii, 119.
- absorption of salts by the (DE LAVERGNE), A., ii, 1100.
- concurrent oxidising and reducing power of (SCHREINER and SULLIVAN), A., ii, 741.
- amount of acid in, and resistance to acids of (ASÖ), A., ii, 439.
- Rosemary oil** (SCHIMMEL & Co.), A., i, 328.
- "**Rosin spirit**," presence of camphene in (GRIMALDI), A., i, 273.
- Rotation**. See under Photochemistry.
- Rubeanic acid**, formation of, in the separation of cadmium and copper (BILTZ and BILTZ), A., ii, 456.
- Rubidium**, fundamental spectrum of (GOLDSCHMIDT), A., ii, 669.
- ultra-red line spectrum of (PASCHEN; RANDALL), A., ii, 1014.
- vapour, absorption and fluorescence of (CARTER), A., ii, 672.
- electrolytic preparation of (V. HEVEY), A., ii, 611.
- and caesium chlorides, relative rates of diffusion in aqueous solution of (MINES), A., ii, 691.
- hydroxide, hydrates of (DE FORCAND), A., ii, 124.
- arseno- and phospho-molybdates (EPHRAÏM and HERSCHEINER), A., ii, 208.
- Rubroquinone** (COMANDELLI), A., i, 552.
- Rumex acetosella*, constituents of (TILLY and CLEWER), T., 1.
- Ruthenium carbonyl** (MOND, HERTZ, and COWAR), T., 809; P., 67.
- Rutin**, occurrence of, in *Tephrosia purpurea* (CLARKE and BANERJEE), T., 1837; P., 213.
- osyritrin, myricolorin, and viologuer-citrin, identity of (PERKINS), T., 1775; P., 213.
- S.
- Sabinic acid**, constitution of (BORGGAULT), A., i, 267.

- Saccharic acids**, electrolytic degradation of (NEUBERG, SCOTT, and LACHMANN), A., i, 218.
- "Saccharin."** See *o*-Benzoisulphinide.
- α*-D-glucosaccharin** and its derivatives (NEF and LUGAS), A., i, 714.
- Saccharinic acids**, formation of (NEF), A., i, 711.
- Safranines**, synthesis of the (SAPOSHNIKOFF), A., i, 782.
- Sahidin** from human brain (FRÄNKEL and LINNERT), A., i, 295.
- Salicin**, hydrolysis of (HUDSON and PAINE), A., i, 83.
- Salicyl alcohol**, estimation of, as tribromophenol bromide (AUTENRIETH and BEUTTEL), A., ii, 552.
- Salicylaldehyde** and sulphuric acid, colour reaction of, with fusel oil (KREIS), A., ii, 552.
- Salicylaldehyde**, 5-nitro-, sodium salt (CLAYTON), T., 1406.
- Salicylaldehyde-β-naphthylhydrazone** (PADOA and GRAZIANI), A., i, 510.
- Salicylaldehyde-1:2:4**, and **1:3:4-xylylhydrazones** (PADOA and GRAZIANI), A., i, 510.
- Salicylaldehyde-1:4:5-xylylhydrazones** (PADOA and GRAZIANI), A., i, 778.
- Salicylamide**, 5-bromo-, *o*- and *N*-benzoyl derivatives of (HUGHES and TITHERLEY), P., 344.
- iodo-** (HAASE), A., i, 740.
- Salicylarsinic acid**. See 3-Carboxy-phenylarsinic acid, 4-hydroxy-
- Salicylic acid**, derivatives of (EINHORN and V. BACH), A., i, 259.
- change of benzoic acid into, in sunlight (NEUBERG), A., ii, 814.
- methyl ester, chlorocarbonate, carbamate, diethyl- and dichlorodimethyl-carbamates of (EINHORN and V. BACH), A., i, 259.
- cholesteryl ester, crystalline form of (ARTINI), A., i, 620.
- salicylic acid**, dinitro-, methyl and ethyl esters (ZINCKE), A., i, 556.
- Withio-** (*o*-hydroxyphenylcarbitronic acid), and its lead salt, methyl ester and disulphide (BLOCH and HÖHN), A., i, 257.
- salicylic acid**, detection of (REICHARD and PELLET), A., ii, 206.
- detection of, in wine (VON DER HEIDE and JACOB), A., ii, 359.
- detection and estimation of, in wines (CATTINI), A., ii, 1007.
- estimation of, by distillation (CASSAL), A., ii, 760.
- estimation of, as tribromophenol bromide (AUTENRIETH and BEUTTEL), A., ii, 552.
- Salicylic acid**, estimation of, in jams (V. FELLEBERG), A., ii, 906.
- Salicylic acids**, moniodo-, preparation of (HAASE), A., i, 740.
- Salicytidaneanthranilic acid** (WOLF), A., i, 736.
- β-Salicyloxy-α-hydroxyisobutyric acid**, ethyl, propyl and isocamyl esters (LES ÉTABLISSEMENTS POULENC FRÈRES, and FOURNEAU), A., i, 386.
- S-Salicylphenazothionium**, dinitro-, hydroxide (BARNETT and SMILES), T., 372.
- Salicylphenylbenzamide** (TITHERLEY), T., 209; P., 9.
- Saline purgatives**, the action of (HERTZ, COOK, and SCHLESINGER), A., ii, 145.
- Saliva**, alkalinity of (BERG), A., ii, 320.
- Salivary glands**, permeability of, to sugar (ASHER and KARACLOW), A., ii, 516.
- secretion (ASHER and KARACLOW; JONA), A., ii, 516.
- rate of, relation of ptyalin concentration to the (CARLSON and CRITCHDEN), A., ii, 516.
- Salol**, melting-point of granules of (PAWLOFF), A., i, 740.
- Salt hydrates**, stable. Isolation of (CYM-MING), T., 593; P., 57.
- Saltpetre**, Chili. See Sodium nitrate.
- Salts**, formation of (BRUNI and SANDONNINI; SANDONNINI), A., ii, 383.
- rate of dissolution of (WAGNER), A., ii, 275.
- coloration of (RASSENFOSE), A., ii, 210.
- ionisation of, in mixtures with no common ion (SHERRILL), A., ii, 570.
- displacement of, from solution by precipitants (ARMSTRONG and EYRE), A., ii, 832.
- basic, constitution of (PICKERING), T., 1851; P., 19.
- double, formation of (FOOTE), A., ii, 505.
- theories of the constitution of (PFEIFFER, FRIEDMANN, and REKATE), A., ii, 876.
- the transformation point of (SCHREINEMAKERS), A., ii, 469.
- fused, electro-capillary phenomena with (V. HEVESY and LORENZ), A., ii, 822.
- hydrated; colorimetric analysis of (DONNAN and HOPE), A., ii, 392.
- inorganic, penetration of, into living protoplasm (OSTERHOUT), A., ii, 335.
- with a common ion, behaviour of, when dissolved in an organic solvent (PHILIP and COURTMAN), T., 1261; P., 140.

- Salts**, mineral, the influence of, on the respiration of germinating seeds (ZALESKI and REINHARD), A., ii, 148.
- influence of, on protein metabolism in plants (ZALESKI and ISRAILSKY), A., ii, 335.
- molten, electrolysis of (LORENZ), A., ii, 179; (KALLAN), A., ii, 928.
- neutral, influence of, on indicators (MICHAELIS and KONA), A., ii, 153.
- organic, action of, on physiological processes (HÜBER), A., ii, 878.
- soluble, effect of, on insoluble phosphates (GREAVER), A., ii, 444.
- See also Metallic salts.
- Salt solutions**, properties of, in relation to the ionic theory (NOYES and FALK), A., ii, 929.
- viscosity of (APPLEBEY), T., 2000; P., 216.
- Sambucus*, hydrogen cyanide in (RAVENNA and TONEGUTTI), A., ii, 442.
- Sambucus ciliata* oil (HAENSEL), A., i, 401.
- Sampshire oil**, fractionation of (DELEPIRE), A., i, 401.
- Samsonite**, a manganiferous silver mineral from the Harz (WERNER and FRAATZ), A., ii, 620.
- Sand**, grey, humic acids of (HOENBERGER), A., ii, 745.
- Sandalwood oil** (SCHIMMEL & Co.), A., i, 758.
- Sandmeyer's reaction**, quantitative conditions of (HELLER), A., i, 240.
- Sandstone**, brown, humic acids of (HOENBERGER), A., ii, 745.
- Sanguinaria canadensis*, alkaloids in the roots of (KOZIEWSKI), A., i, 874.
- Sanguinarine periodide** (KOZIEWSKI), A., i, 875.
- Sanidin**, influence of radium rays on the coloration of (BRAUNS), A., ii, 9.
- Santalene dihydrochloride** (SENNLER), A., i, 181.
- a-Santalol**, constitution of (SENNLER), A., i, 574.
- Santenone**, oxime of (SCHIMMEL & Co.), A., i, 758.
- Santenone alcohol**, phenylurethane of (SCHIMMEL & Co.), A., i, 758.
- Santenyl methyl ether** (SCHIMMEL & Co.), A., i, 758.
- Santonin**, action of sulphuric and phosphoric acids on (BARELLINI and SILVESTRI), A., i, 39.
- Saponin**, detection of, in beer, wine, and aerated water, by hemolysis (RUSCONI), A., ii, 559.
- Sapphires**, synthetical production of (VERNEUIL), A., ii, 212; (MOSSES), A., ii, 965.
- Savin**, oil of (ELZE), A., i, 528.
- Scammony resin**, composition of (GOLK and FLUTEAUX), A., i, 402.
- Scandium**, distribution of (FERRELL), A., ii, 509.
- salts of (CROOKES), A., ii, 714; (MEYER and WINTER), A., ii, 853.
- ammonium carbonate (MEYER, WINTER, and SPETER), A., ii, 854.
- sodium carbonate (MEYER, WINTER, and SPETER), A., ii, 854.
- Scatole** (3-methylindole), a new reaction of (SASAKI), A., ii, 166.
- indican and iodine differentiation between, in Jaffe's indican reaction (SPIETHOFF), A., ii, 808.
- Schardinger's reaction** (BREDIG and SOMMER), A., ii, 284.
- Schaum's substance B**, the nature of (TRIVELLI), A., ii, 611.
- Schenck's law**, testing of (BENNOTTI), A., ii, 1030.
- Schiff's bases** (*azils*), isomerism of (MANCHOT and FERLON), A., i, 33; (ANSELMI), A., i, 174.
- coloured salts of (MOORE), A., i, 280.
- Scopoletin**, dibromo-, and its acetyl derivative (MOORE), T., 2229.
- Scutellarein**, and its derivatives (GOLDSCHMIEDT and ZERNER), A., i, 576.
- Scutellarin**, hydrolysis of (GOLDSCHMIEDT and ZERNER), A., i, 576.
- Scyllium edulus*, organs of, purine metabolism in the (SCAFFIDI), A., ii, 626.
- Seals**, the bile of (HAMMARSTEN), A., ii, 879.
- Sea-urchin**, living cells of, oxidation in (WARBURG), A., ii, 628.
- Sea-urchin's eggs**. See Eggs.
- Sea-water**. See under Water.
- Seeds**, relation of methylpentosans to pectosans in (BORGHESANI), A., ii, 632.
- action of potassium salts on the formation of sucrose in (DE PLATO), A., ii, 742.
- germination of, importance of maculages in the (RAVENNA and ZAMORANI), A., ii, 991.
- formation of hydrocyanic acid in the germination of (RAVENNA and ZAMORANI), A., ii, 1099.
- germinating, lecithin and lecithides in (BERNARDINI and CHIARELLI), A., ii, 991.
- germinating, the influence of mineral salts on the respiration of (ZALESKI and REINHARD), A., ii, 148.

- Seeds, ripe, their content in organic phosphorus and the relation between amide nitrogen and the other nitrogenous forms (PAKROZZANI), A., ii, 438.
- ripening, protein formation in (SCHULZE and WINTERSTEIN), A., ii, 644.
- of *Bursaria spinosa*, chemical examination of the oil from (GRIFFITHS), A., ii, 800.
- of *Cucurbita citrullus* (water melon), chemical examination of (POWER and SALWAY), A., ii, 337.
- of *Cucurbita Pepo* (pumpkin), chemical examination of (POWER and SALWAY), A., ii, 338.
- of *Datura Metel*, presence of allantoin in the (DE PLATO), A., ii, 742.
- of *Pinus Koraiensis*, composition of protein from the (YOSHIMURA), A., ii, 442.
- of cultivated plants, composition of (SCHULZE), A., ii, 740.
- Selenium in Altai minerals (PILIPENKO), A., ii, 45.
- dynamic allotropy of (KRUYS), A., ii, 28.
- photoelectric property of (BROWS), A., ii, 573.
- colloidal, preparation of (v. WEIMARN and MALINSCHEFF), A., ii, 941.
- preparation of colloidal solutions of (POCHETTINO), A., ii, 119.
- high sensibility cells (BROWN), A., ii, 573.
- action of hydrogen on, in the presence of another element (PÉLABON), A., ii, 119.
- action of, on magnesium cyclohexyl chloride (MAILHE and MURAT), A., ii, 374.
- compounds of, with chlorine and bromine (BECKMANN and HANSMAN), A., ii, 287.
- Selenium oxide, heat of, formation of, and heat of combination of, with sodium oxide (MIXTER), A., ii, 585.
- Selenious acid, estimation of volumetrically (MARINO), A., ii, 155.
- selenium, estimation of, by means of silver (PERKINS), A., ii, 659.
- selenophen (FOA), A., i, 187.
- selenophosphates. See under Phosphorus.
- seligmannite, from Binn, Switzerland (FÜRER), A., ii, 781.
- l-selinene, and its dihydrochloride (SCHIMMEL & Co.), A., i, 328.
- semicarbazide semicarbazones, constitution and behaviour of (RUFF and KESSLER), A., i, 15.
- Semicarbazone, $C_{10}H_{19}O_2N_2$, from the oxidation of apofenchene (BOTVEAULT and LEVALLOIS), A., i, 687.
- Semicarbazones, effect of negative substituents on the formation of (RUFF and KESSLER), A., i, 93.
- mutual replacement of, and phenylhydrazones (KNÖPPER), A., i, 432.
- Separating apparatus (JACOBSON and DUNSMORE), A., ii, 704.
- Serine, occurrence of, in human perspiration (EMDEN and TACHAU), A., ii, 981.
- dipeptides from (FISCHER and ROESNER), A., i, 657.
- Serological studies (ABDERHALDEN and PINGSOHN), A., ii, 318, 319; (ABDERHALDEN and IMNISCHE); (ABDERHALDEN and ISRAEL); (ABDERHALDEN and SLEESWYK); (ABDERHALDEN and BRAHN), A., ii, 319; (ABDERHALDEN and PINGSOHN), A., ii, 736; (ABDERHALDEN and KATZBERGER), A., ii, 1093.
- Serotonin, and its octa-acetyl-derivative (POWER and MOORE), T., 1109; P., 124.
- Serum, free from electrolytes, preparation of, by electrical dialysis (DILRE and GORGOLEWSKI), A., ii, 515.
- drying of (FRANKEL and ELFER), A., ii, 1081.
- electrical conductivity of (FERN), A., ii, 177; (LUCCHARDT), A., ii, 226.
- action of, on pancreatic lipase (ROSENHEIM and SHAW-MACKENZIE), A., ii, 517.
- placental and retroplacental, ionic concentration in (LOH and HUGGEL), A., ii, 326.
- multivalent precipitating, the capacity of the animal body to produce a (STRZYZOWSKI), A., ii, 623.
- normal, syphilitic and tumour, the non-coagulable nitrogen and the phosphorus content of (TAKIMURA), A., ii, 636.
- Serum-albumin, isoelectric and relative acidity constants of (MICHAELIS and MOSTYNSKI), A., i, 287.
- Serum proteins, action of alkalis on (SCHMIDT), A., ii, 319.
- osmotic pressure of ionising salts of (ROAF), A., i, 344.
- equilibrium of, with acids and alkalis (MOORE and BIGLAND), A., ii, 313.
- action of, on the isolated mammalian heart (GOEHAM and MORRISON), A., ii, 324.
- nutritive value of (IMABUCHI), A., ii, 322.
- Sesame oil, reaction of, with furfuraldehyde (VAN ECK), A., ii, 556.

- Sesquiterpene**, $C_{15}H_{24}$, from the seeds of *Monarda grandiflora* (LEIMBACH), A., i, 186.
- Sesquiterpenes** (DEUSSEN and PHILIPP), A., i, 575.
- Sesquiterpene alcohols** (KIMURA), A., i, 628.
- Shaking apparatus**, for boiling with a reflux condenser (MONTAGNE), A., ii, 485.
- Siderite**, magnetic dichroism of, in liquids (MESLIN), A., ii, 99.
- Silicate fusions**, with artificial mixtures (HAEMMERLE), A., ii, 721.
- Silicic acid and Silicates**. See under Silicon.
- Silicon** from silicates (GRÖPFEL), A., ii, 289.
- amorphous (WILKE-DÖRFERT), A., ii, 281.
- and carbon, morphotropic relations between corresponding compounds of (JERUSALEM), T., 2190; P., 249.
- Silicon nitrides** (WEISS and ENGELHARDT), A., ii, 122.
- monosulphide (CAMBI), A., ii, 952.
- sulphide, formation of, in the disulphurisation of iron (FIELDING), A., ii, 32.
- Silicic acid** in Whartonian jelly (SCHULZ), A., ii, 225; (SERRA), A., ii, 407.
- vapour pressure and velocity of dehydration of powdered (TSCHERNAK), A., ii, 407.
- colloidal, history of (SMITH and BENNETT), A., ii, 500.
- gelatinisation of (PAFFARD and SADOWSKI), A., ii, 593.
- Silicates**, in the earth's crust, modes of weathering (VAN BENNEKEN), A., ii, 419.
- constitution of (MANCHOT), A., ii, 1060.
- silicon from (GRÖPFEL), A., ii, 289.
- fused, application of the laws of eutectics to (FLAWITZKY; ILACKE), A., ii, 510.
- estimation of ferrous oxide in (DITTRICH and LEONHARD), A., ii, 1062.
- titrimetric estimation of ferrous oxide and boric acid in (FROMME), A., ii, 351.
- estimation of, alkalis in (DORING), A., ii, 348.
- See also Metallic silicates.
- Silicon organic compounds** (CHALLENGER and KIRTING), T., 142, 755; P., 3, 65.
- Silicon**, estimation of, in ferrosilicon (PREUSS), A., ii, 346; (NEUMANN), A., ii, 547.
- Silk**, Chefoo, mono-amino-acids from (ANDERHALDEN and WEIDEN), A., i, 289.
- Italian, amino-acids of** (ROOSE), A., i, 794.
- Japanese, amino-acids of** (SUWA), A., i, 794.
- Tai-Tsao-Tsam, mono-amino-acids from** (ANDERHALDEN and SCHMID), A., i, 289.
- Silks**, composition and cleavage products of (ROOSE; SUWA), A., i, 794.
- Silk peptone**, preparation and action of, on peptolytic enzymes (ANDERHALDEN and STEINBECK), A., ii, 950.
- Silver**, atomic weight of (RICHARDS and WILLARD), A., ii, 292; (HUGHES), A., ii, 844.
- ultra-red line spectrum of (PASCHE; RANDALL), A., ii, 1014.
- electrochemical equivalent of (LAFORE and DE LA GORCE), A., ii, 178.
- precipitated (DAS), A., ii, 209.
- influence of dissolved gases on the electrode-potential of the system, silver acetate and (JAQUET), A., ii, 383.
- and thallium, liquid crystalline phases of the monohalides of (SROUTENBERG and HUTH), A., ii, 295.
- hydrosols, coagulation of (DORINGKEL), A., ii, 589.
- use of, in the estimation of molybdenum, vanadium, selenium, and tellurium (PREKINS), A., ii, 650.
- Silver alloys**, with aluminium, electrical properties of (BRONSTEWEL), A., ii, 715.
- with cadmium, equilibrium diagram of (BROXT and OBERGREN), A., ii, 953.
- with cobalt (DU ELLIEZ), A., ii, 716.
- with copper (FIEBIG), A., ii, 851.
- with copper, electrical conductivity and hardness of (KRYENKOFF, PRISHIN, and SENKOWSKY), A., ii, 925.
- with mercury (JONES), T., 356; P., 47.
- with nickel (VIGORANT), A., ii, 716.
- with sodium, equilibrium of (RUBEN), A., ii, 1062.
- Silver salts**, catalytic action of, on chlorates in the presence of aniline hydrochloride (FAGG; VIBOLD), A., ii, 1107.
- solubility of sparingly soluble (WHITBY), A., ii, 612.
- and aliphatic iodides, kinetics of the reaction between (DOXAN and POTTS), T., 1882; P., 272.

- silver salts**, organic, decomposition of (ANGELI and ALESSANDRI), A., i, 605.
- silver antimonides** (LIEMSCH), A., ii, 502.
- bromide, peptisation of (LIESEGANG), A., ii, 953.
- bromides, action of hydrogen peroxide on (TRIVELLI), A., ii, 502.
- carbonate in solution, condition of (SPENCER and LE PLA), A., ii, 47.
- chloride, solubility of, at high temperatures (MELCHER), A., ii, 293.
- solid, conduction of electricity through (LE BLANC and KERSCHBAUM), A., ii, 382, 926.
- iridichloride and iridochloride (DELEPINE), A., ii, 34.
- dichromate and sulphate, mixed crystals of (VAN NAME and BOSWORTH), A., ii, 410.
- halides, photochemical decomposition of (TRIVELLI), A., ii, 502.
- theory of the ripening process of (TRIVELLI), A., ii, 90.
- catalytic action of (SENTER), T., 346; P., 23.
- photo-halides of (REINDERS), A., ii, 1062.
- iodide, emulsion of (THUM), A., ii, 1063.
- nitrate, formation of, from silver sulphide (GRUENER), A., ii, 953.
- ammonium nitrate (SCHREINEMAKERS and DE BAAT), A., ii, 489.
- peroxide, so-called electrolytic (BOSCH), A., ii, 34.
- sulphate, solubility of, in alkali sulphates (BARRE), A., ii, 710.
- and dichromate, mixed crystals of (VAN NAME and BOSWORTH), A., ii, 410.
- and colloidal sulphur, velocity of the reaction between (RAFFO and PIERONI), A., ii, 839.
- sulphite and its alkali double sulphites, action of heat on, and formation of a dithionate (BAUMONT), A., ii, 125.
- tellurides (PELLINI and QUERCIGN), A., ii, 1063.
- Argentodiammonium** iridochloride (DELEPINE), A., ii, 35.
- Silveramine** molybdenum cyanide. (ROSENHEIM, GELFUNKEL, and KOHN), A., i, 102.
- Silver**, qualitative test for small quantities of (ARMANI and BARBONI), A., ii, 659.
- detection and estimation of very small quantities of (WHITBY), A., ii, 654.
- Silver**, estimation of, by electrolytic means (BENNER), A., ii, 999.
- and mercury, volumetric separation of (RUPP and LEHMANN), A., ii, 350.
- Siphon**, improved (JACOBSON and DISAMORE), A., ii, 601.
- for use with carbonyls (RAYMOND), A., ii, 892.
- Skin**, importance of, as a depot of chlorine (PASTBERG), A., ii, 791.
- changes in the, on application of ethyl chloride (FRANZ and REEDIGER), A., ii, 1088.
- Slags**, basic, estimation of total phosphoric acid in (GUERRY and TOUSSAINT), A., ii, 73.
- Sleep**, winter, physiology of (REACH), A., ii, 787.
- Soap emulsions**, physico-chemical theory of (DONNAN and POTTS), A., ii, 933.
- Soaps**, inhibition of hemolysis by (MEYERSTEIN), A., ii, 223.
- alkali, hydrolysis of aqueous alcoholic solutions of (HOLDE, DÜSCHER, and MEYERHEIM), A., i, 533.
- formalin, estimation of formaldehyde in (ALLEMANN), A., ii, 465.
- soluble, colloidal properties of (BORTAZZI and VICTOROFF), A., i, 537.
- Soap solutions**, electrical conductivity of (McBAIN and TAYLOR), A., ii, 177.
- detergent action of (SPRING), A., i, 6153.
- Soda-sandime**, from Mitrowitz (ANGEL), A., ii, 783.
- Sodium**, spectra of (ZICKENDRANT), A., ii, 171.
- spark spectrum of (SCHILLINGER), A., ii, 369.
- ultra-red line spectrum of (PASCHE), A., ii, 1014.
- compressibility of, at different temperatures (PIOTZ), A., ii, 187.
- electrode. See Electrode under Electrochemistry.
- behaviour of lithium towards (MASING and TAMMANN), A., ii, 610.
- method of demonstrating the action of, on water (REBENSTORFF), A., ii, 604.
- protective action of, for plants (OSTERHOUT), A., ii, 62.
- Sodium alloys**, with mercury, action of, on methylene ethers (SALWAY), T., 2413; P., 293.
- with silver, equilibrium of (QUERCIGN), A., ii, 1062.
- Sodium aluminate solutions**, constitution of (SLADE), P., 236.

- Sodium**, arsenosomolybdate (EPHRAIM and FEIDEL), A., ii, 301.
 diborate, technical preparation of (LEVI and CASTELLANI), A., ii, 501.
 action of solutions of, on zinc salts (BORCHERS), A., ii, 1065.
 titration by means of, in the presence of glycerol (TANANAEFF and TSUKERMANN), A., ii, 158.
 carbonate, stable hydrates of (CEM-MING), T., 593; P., 57.
 use of, for oxidising purposes (DREISS), A., ii, 802.
 and strontium sulphate, the reaction between (HERZ), A., ii, 849.
 action of, on insoluble carbonates (OECHEMER DE CONINCK), A., ii, 846.
 aluminium carbonate, Dawsonite, a (GRAHAM), A., ii, 136.
 hydrogen carbonate, constitution of (BIEHR), A., ii, 775.
 scandium carbonate (MEYER, WINTER, and SPETER), A., ii, 854.
 chloride, vapour pressure of aqueous solutions of (KRAUSKOPF), A., ii, 683.
 boiling point of (EMICH), A., ii, 846.
 physiology of (COHNHEIM, KREGLINGER, and KREGLINGER), A., ii, 138.
 influence of the concentration of hydroxyl ions in a solution of, on the relative anti-toxic action of potassium and calcium (LOEB), A., ii, 1095.
 effect of sodium cyanide on the poisonous action of, on sea-urchin's eggs (LOEB and WATKINS), A., ii, 1096.
 hydroxide, action of metals on, fused (LE BLANC and BERGMANN), A., ii, 123.
 iodide, estimation of, in animal tissues (HANSZIK), A., ii, 748.
 zinc iodides (EPHRAIM and MOPEL), A., ii, 851.
 manganate and its hydrates (AUGER), A., ii, 710.
 nitrate, efficiency of, as a fertiliser (VASHA), A., ii, 538.
 phosphates, ionisation of, in dilute solution (RINGER), A., ii, 306.
 hydrogen phosphate, hydrates of (KILAWAKI), A., ii, 846.
 trioxyselenophosphate (EPHRAIM and MASLER), A., ii, 297.
 phosphotungstate as a reagent for uric acid and other reducing substances (CEVELLO), A., ii, 82.
 Selenium, action of, on the pro-duction of carbon dioxide from yeast (KORSAKOFF), A., ii, 989.
 silicate and ferric chloride, reaction between solutions of (JORDIS and LINCKE), A., ii, 418.
 sulphate, fluoride, and chloride, the ternary system (WOLTERS), A., ii, 775.
 heat of hydration of (WETZIE; JORNSSEN), A., ii, 392.
 reduction of, by carbon (COLSON), A., ii, 34.
 and potassium sulphates, transformations in mixed crystals of (NACKEN), A., ii, 501.
 sulphite, double salt of zinc hyposulphite and (FARBENFABRIKEN VORM. F. BAYER & Co.), A., ii, 411.
 hyposulphite, constitution of (HAZLEY and BERTHSEN), A., ii, 291.
 tellurides (PELLINI and QUEBIGN), A., ii, 1062.
 dithionite and trithionate, action of iodine on (MULLER), A., ii, 154.
Sodium organic compounds:—
 Sodium alkyl carbonates (FRANCH-MONT), A., i, 4.
 alkyl compounds and synthesis thereof (SCHONIGIN), A., i, 345.
 alkyl oxides, action of, on ethyl acetoacetate (KUMMEKOS), A., i, 708.
 alkyl thiosulphates, action of alkalis on (PRICE and TWISS), T., 1175; P., 136.
 arylimides (DEITSCHER GOLD- & SILBER-SCHNEIDE ANSTALT), A., i, 164.
 ferrocyanide, excretion of, by the kidney (WASHEIKO), A., ii, 450.
 molybdenum cyanide (ROSENHEIM, GARFUNKEL, and KOHN), A., i, 102.
 phenyl carbonate, action of acetone on (MOLL VAN CHARANTE and MONTAGNE), A., i, 311.
Sodium, estimation of (BULL, T., 1408; P., 169).
Soils, solution of (CAMERON), A., ii, 616.
 occurrence of arsenic in (HEADEN), A., ii, 890.
 occurrence of manganese in (GUTHRIE and CONEN), A., ii, 444.
 bacteriology of (DZIERZBUCKI), A., ii, 532.
 importance of osmotic pressure and of electrolytic conductivity in judging (KÖBE, HASENBÄUMER, and MEYERING), A., ii, 1194.

- ils, effect of alkaloidal solutions on (OTTO and KOOPER), A., ii, 993.
 transformation of calcium cyanamide in (ULPIANI), A., ii, 890.
 effect of carbon disulphide on decomposition processes in (SCHERPE), A., ii, 891.
 accumulation of nitrogen in, by free bacteria (KOCH), A., ii, 60 (KRAINSKY), A., ii, 236.
 ammonia in (RUSSELL), A., ii, 1104.
 denitrification in (KOCH and PETTIT), A., ii, 333.
 denitrification and accumulation of nitrogen in (MARR), A., ii, 536.
 ammonia and nitrate formation in (LIPMAN and BROWN), A., ii, 435.
 solution of phosphoric acid in (PEROTTI), A., ii, 1165.
 retention of superphosphate in (GREISENEGGER), A., ii, 537.
 action of different amounts of copper in, on the growth of plants (SIMON), A., ii, 34.
 nitrogenous compounds in, influence of carbon disulphide on the decomposition of (SCHERPE), A., ii, 339.
 insoluble phosphates of, utilisation of by higher plants (DE GRAZIA), A., ii, 436.
 compounds of, harmful, as affecting the ratio of plant nutrients (SCHREINER and SKINNER), A., ii, 740.
 extracts of, estimation of nitrogen in (DENSCH), A., ii, 70.
 arable, formation of micas in (BIELER-CHATELAN), A., ii, 535.
 nitrogen economy of (PFEIFFER, GUTTMAN, and THIEL), A., ii, 535.
 black cotton, in India, colour of (ANNETT), A., ii, 535.
 peat, nitrogenous compounds in (JODIDI), A., ii, 339.
 analysis of (PETTIT), A., ii, 65.
 acidity of, Albert's method for determining (SÜCHTING and ARND; ALBERT), A., ii, 361.
 estimation of magnesium in, in the presence of manganese (DE SORNAV), A., ii, 243.
 estimation of assimilable potassium in (BIELER-CHATELAN), A., ii, 453.
 oil bacteria. See under Bacteria.
 oil, estimation of the lecithin content of (RIEDEL), A., ii, 662.
 olanzace, migration of alkaloids in grafts of (JAVILLIER), A., ii, 646.
 olarisation. See under Photochemistry.
 olid, impossibility of superheating a (BERTHOUD), A., ii, 825.
 solutions. See Solutions, solid.
 Solids, specific heats of, relation between, and temperature (MAGNUS and LINDEMANN), A., ii, 580.
 measurement of magnetic susceptibility of (PASCAL), A., ii, 433.
 molecular volumes of (STEPHENSON), A., ii, 932.
 perfectly miscible, and their solid solutions, vapour pressures of (VAN-STOKE), T., 429; P., 47.
 conduction of electricity in (KIRKINBERGER and SCHILLING), A., ii, 481.
 adsorption of iodine by (GUTHARD), A., ii, 772.
 and liquids, thermal properties of (LUSANA), A., ii, 589.
 viscosity of, at low temperatures (GUYE and FRIEDENICKE), A., ii, 21.
 Solubilities, determination of, with small quantities of substance (STOLTZENBERG), A., ii, 17.
 Solubilities, below and above the critical temperature (TYRER), T., 621; P., 62.
 Solubility, influence of (HERZ), A., ii, 182, 275.
 a contribution to the theory of (TYRER), T., 1778; P., 205.
 relation between, and the physical state of the solvent in the absorption of carbon dioxide by *p*-azoxyphenetole (HOMFRAY), T., 1669; P., 197.
 of gases in water, influence of colloids and fine suspensions on the (FINDLAY and CREIGHTON), T., 536; P., 44.
 Solubility product, inconstancy of the (HILL), A., ii, 336.
 Solute, volume of a, in solution (TYRER), T., 2620; P., 326.
 and solvent, energy relations of (GARVER), A., ii, 395.
 Solutions, critical phenomena of (TIMMERMAN), A., ii, 19.
 volume of a solute in (TYRER), T., 2620; P., 326.
 in aqueous solutions (LE BLANC and SCHMANDT), A., ii, 275.
 of salts, rate of (WAGNER), A., ii, 275.
 of two salts with a common ion, in an organic solvent (PHILIP and COURTMAN), T., 1261; P., 110.
 Solutions (SCHWEISS), A., ii, 913, 1039.
 theory of (JAKOWSKIN), A., ii, 274; (WASHBURN), A., ii, 1044.
 kinetic theory of, and diffusion (THOMER), A., ii, 191.
 studies of the processes operative in (WORLEY, ARMSTRONG and WORLEY; GLOVER; WORLEY and GLOVER), P., 298; (ARMSTRONG and WHEELER; ARMSTRONG and CROTHERS; ARMSTRONG), P., 299; (ARMSTRONG and EYRE), A., ii, 832.

- Solutions, physical properties of** (HEYDWEILLER), A., ii, 338.
 properties of, at their critical solution-temperature (SCHUKAROFF), A., ii, 192.
 composition and vapour tension of (VERVSKY), A., ii, 1033.
 magnetism of (DRAPIER), A., ii, 99.
 specific heat of (MAGIE), A., ii, 265.
 clearing and decolorising (NEUBERG), A., ii, 446.
 adsorption of, by charcoal (SCHMIDT), A., ii, 1041.
 of inorganic salts in formamide, electrolysis of (RÖHLER), A., ii, 684.
 of normal liquids, contraction constant of (v. BIRON), A., ii, 394.
 of salts, slow change in the nature of (SHRINE), A., ii, 276.
 aqueous, density and electrical conductivity of (HEYDWEILLER), A., ii, 108.
 density and degree of dissociation of (TERESCHIN), A., ii, 190.
 aqueous, crystallisation and dissolution in (LE BLANC and SCHWABER), A., ii, 278.
 conductivity of, at zero (SLOAN), A., ii, 820.
 surface tension of, and Laplace's constant (LEWIS), A., ii, 933.
 non-aqueous, electrical conductivity of, at low temperatures (WALDEN), A., ii, 684.
 colloidal and crystalloidal, existence and properties of dispersive systems in the region between (SVEBERG), A., ii, 108.
 dilute, changes in volume in the formation of (DAWSON), T., 1041, 1896; P., 116, 202.
 ethereal, apparatus for evaporating (GIRDWOOD), A., ii, 117.
 solid, vapour pressures of (VANSTONE), T., 429; P., 47.
 of metals and the electron theory (SCHENCK), A., ii, 482.
 of metal, thermo-electric forces of (BERNARDINI), A., ii, 1030.
 crystalline solid, as disperse systems of different degrees of dispersity (v. WEIMAN), A., ii, 696.
 water-alcohol, van Laar's theory of the contraction in (DUBOSCHNEVSKY and ROSCHEN-SIVENSKY), A., ii, 931.
Solvent, and solute, energy relations of (GARYER), A., ii, 398.
Solvents, influence of, on the equilibrium constant (PISARZEWSKY and HELENOWSKY), A., ii, 505.
Solvents, influence of, on the separation of optically active compounds (FARRENSEN and STEVENSON), T., 2119; P., 238.
 mixed, partition law (HILTZ and KURZER), A., ii, 1045.
 organic, solubilities of organic substances in (TYMEN), T., 1778; P., 205.
Sorbic acid, methyl ester (POKSEN and RÖHDE), A., i, 847.
Sorbic acid, γ -bromo-, and its potassium salt (VIGIER), A., i, 461.
Sorbitol, starch formation from, in Rosaceae (TREBOUX), A., ii, 61.
Space, of four dimensions, representation of physical phenomena in (FRANK), A., ii, 840.
Spaces, dead (LIESEGANG), A., ii, 1062.
Spark, new radiant emission from the (WOOD), A., ii, 915.
Spark gap. See under Electrochemistry.
Sparteine, amount of, in common broom (CHEVALIER), A., ii, 594.
 and its methochloride, triethylchlorides of (SCHOLTZ), A., i, 97.
Spearmint oil, constituents of (EZZE), A., i, 865.
Specific gravity. See Density.
Specific heat. See under Thermochemistry.
Spectra. See under Photochemistry.
Sphingomyelin, preparation of (ROSEHEIM and TERB), A., ii, 1085.
Spinal cord, composition of the (FRANKL and DIMITZ), A., ii, 1088.
Spleen, nucleo-protein of (SATO), A., ii, 56.
 iron-containing lipoids in the (BROWN), A., ii, 630.
Sponges, the iodine complex in (WHEELER and MENDEL), A., ii, 143.
Stachydrine, constitution and derivatives of (SCHULZE and THIERK), A., i, 62; ii, 743; (TIEBER), A., i, 697; (ENGELAND), A., ii, 835.
Stachyose (NEUBERG and LACHMANN), A., i, 225; (SCHULZE), A., i, 610.
 presence of, in halimite plants (PILAVET), A., ii, 336.
 in the roots of *Ranunculus laciniata* (KROTH), A., ii, 886.
Stachys tubers, isolation of stachydrine and other bases from (SCHULZE and THIERK), A., ii, 743.
Stannic compounds. See under Tin.
Star anise oil (SCHUMMEL & CO.), A., i, 329.
Starch, formation of, from sorbitol in Rosaceae (TREBOUX), A., ii, 61.
 coagulation of, by freezing (MALLAS and MOSCHKOFF), A., i, 301.

- Starch**, colloidal properties of (BOTTAZZI and VICTOROFF), A., i, 655.
velocity of saccharification of (VAN LAER), A., ii, 839.
- Starch**, purification of (MALFITANO and MOSCHOFF), A., i, 817.
fixation of bases by (FOUARD), A., i, 225.
action of hydracids and hydrolysing agents on (OECHSNER DE CONINCK), A., i, 655.
influence of bile salts on the pancreatic digestion of (BUGLIA), A., ii, 627.
Lintner's soluble, properties of (CLARK), A., i, 544.
the iodine reaction for (HARRISON), P., 252.
indicator for iodometric titrations (MATHIEU), A., ii, 747.
- Starch Gmelin*, leaves of, secretion of salts by the (SOITSCHERBACK), A., ii, 442.
- Stearic acid**, melting and solidifying points of, mixtures of, with palmitic and oleic acids (CARLINEANT and LEVI-MALVANO), A., i, 5, 6.
- Stearic acid**, *cis- γ -dihydroxy*, (ARNAUD and POSTERNAK), A., i, 356.
dihydroxy-(ARNAUD and POSTERNAK), A., i, 459.
- Δ^7 - and Δ^8 -Stearolic acid** (ARNAUD and POSTERNAK), A., i, 459.
- Stearolic acids**, reduction of, and isomerism of their hydriodo-derivatives (ARNAUD and POSTERNAK), A., i, 356.
- Stearyl- β -alanine** (ABDERHALDEN and FUNK), A., i, 227.
- Stearyl-glycine** (ABDERHALDEN and FUNK), A., i, 227.
- Stearyl-L-tyrosinyl stearate** (ABDERHALDEN and FUNK), A., i, 227.
- Steatite**, adsorption by (ROHLAND), A., ii, 615.
- Steel**. See under Iron.
- Stellaria media*, physiological meaning of the hairs of (KNY), A., ii, 443.
hairs of, protein in (JAMESON), A., ii, 645.
- Stelznerite**, identity of, with antlerite (SCHALLER), A., ii, 1076.
- Stereoisomerism** of tervalent nitrogen compounds, a supposed case of (JONES and WHITE), T., 632; P., 57.
of quinevalent nitrogen (SCHOLTZ), A., i, 834.
- Stillbene**, *oo'-di*bromo-, afflicts *di*bromide and *oo'-di*bromo-*aa'*-*di*cycano- (WISLICENUS and FISCHER), A., i, 621.
- Stimulation**, of, prematory ripening (VINSON), A., ii, 335.
- Stovaine** and cocaine, comparative action of (VELEY and WALLER), A., ii, 228.
- Straw**, disinfection by the incomplete combustion of (TRILLAT), A., ii, 232.
- Strontium**, atomic weight of (THORPE and FRANCIS), A., ii, 209.
ultra-red line spectrum of (RANDALL), A., ii, 1014.
metallic (GLASCOCK), A., ii, 954.
crystalline, preparation of (GUNTZ and GAILLOT), A., ii, 1064.
- Strontium carbonate**, action of alkali nitrates on (OECHSNER DE CONINCK), A., ii, 612.
zinc chloride, and iodide (EPHRAIM and MODEL), A., ii, 851.
nitrate and hydroxide, solubility of, in the presence of each other (PARSONS and PERKINS), A., ii, 1064.
mercuric nitrite (RAY), T., 326; P., 7.
oxyselenophosphate (EPHRAIM and MAILER), A., ii, 207.
sulphate and sodium carbonate, the reaction between (HERZ), A., ii, 849.
- Strophanthine**, influence of, on the electro-cardiogram (STRAUB), A., ii, 434.
action of, on the heart (STRAUB; WRESCHININ), A., ii, 1094.
action of, on the blood-vessels (KASATAN), A., ii, 1094.
- Strophanthus strobilatus*, pharmacological action of, and its use as an arrow poison (FRASER and MACKENZIE), A., ii, 639.
- Strychnine** and allied alkaloids (PERRIN and ROBINSON), T., 305; P., 24.
action of cyanogen bromide on (MOSSLER), A., i, 275.
action of, on muscle (VELEY and WALLER), A., ii, 331.
bromine derivatives of (CIUSKA and SPACLIARINI), A., i, 583.
halogen derivatives of, action of acetone on (BYRAZEWSKI and DZIERZYŃSKI), A., i, 873.
- Strychnine perchlorate** (HOFFMANN, RORN, HÖROTH and METZLER), A., i, 819.
- Strychnine, *di*bromo-, oxide** (BYRAZEWSKI and NOWOSIELSKI), A., i, 874.
peroxide (MOSSLER), A., i, 584.
- Strychnine**, new test for (MALAQUIN), A., ii, 165.
- Strychninesulphonic acid** I, amino-, bromo-, bromonitro-, chloro-, *di*-chloro-, and nitro-, and their derivatives (LEUCHS and BOLL), A., i, 766.
*iso*Strychninesulphonic acid I, and nitro-, and their derivatives (LEUCHS and BOLL), A., i, 767.

- Strychninoanilide** (LEUCHS and REICH), A., i, 768.
- Strychninolone** and its derivatives (LEUCHS and REICH), A., i, 768.
- Strychninonic acid**, and its methyl ester and their hydrates, and nitro- (LEUCHS and REICH), A., i, 768.
- bromo-** (LEUCHS and BOLL), A., i, 767.
- Strychnos alkaloids** (LEUCHS and LEUCHS), A., i, 425; (LEUCHS and BOLL), A., i, 766; (LEUCHS and REICH), A., i, 767.
- Styrene**, polymerisation of (STROBE and POSNJAK), A., i, 235.
- Styrene**, ω -bromo-, hydrocarbons from (RUPE and PROSKE), A., i, 367.
- 3:5-dibromo-2-hydroxy-**, and its acetate, also its bromide and corresponding acetate, and ω -3:5-*tert*-bromo-2-hydroxy-, and its acetate and methyl ether (FRIES and MOSKOPF), A., i, 332.
- Styrenes**, and terpenes, heats of combustion of (AUWERS, ROTH, and EISENLOHR), A., ii, 586.
- Styrylacrylhydroxamic acid** (POSNER and RUDKE), A., i, 847.
- Styryl *n*-butyl ketone**, and its phenylhydrazone (AUWERS and VOSS), A., i, 71.
- 2-Styrylconmarone**, derivatives of (ABEYIN and V. KOSANECKI), A., i, 631.
- Styryl *ortho*-hexyl ketone** and its dibromide (KÖHLER and BUENLEY), A., i, 392.
- styrylitaconic acid**, anhydride of (FICHER and WALTER), A., i, 29.
- Styryl methyl ketone-phenylhydrazone**, *p*-nitro- (AUWERS and VOSS), A., i, 71.
- Styryl α -naphthyl ketone**, *p*-nitro- (SCHOLZ and MEYER), A., i, 562.
- α - and γ -Styryl nonyl ketone**, derivatives of (SCHOLZ and MEYER), A., i, 562.
- Styryl *n*-nonyl ketone-phenylhydrazone** (AUWERS and VOSS), A., i, 71.
- Styryl isopropyl ketone** (AUWERS and VOSS), A., i, 76.
- Suberic acid**, ethyl hydrogen ester and its chloride and *p*-toluidide (BLAISE and KUHNLE), A., i, 293.
- Sublimation** by the dynamical method (SCHEFFER), A., ii, 481.
- Substance**, $\text{C}_4\text{H}_5\text{ON}_7$, and its copper salt, from aminoguanidine diazohydroxide and sodium hydroxide (HOFMANN HOCK, and ROHR), A., i, 447.
- $\text{C}_4\text{H}_5\text{N}_4$, from azoimide and methyl-carballyamine (OLIVERI-MANDALA), A., i, 343.
- Substance**, $\text{C}_4\text{H}_5\text{ON}_7$, from triazomethyl-carbimide and water (FORSTER and MÜLLER), T., 1064.
- $\text{C}_4\text{H}_5\text{O}_2\text{S}_2\text{Na}_2\text{Hg}$, from hydroxymercury-acetic aldehyde and sodium thiosulphate (SCHÖZLER and SCHRAUTH), A., i, 460.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}_3$, from α -methazonic anhydride and water (STEINSKOPF, BOHRMANN, GRÜNPPF, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 808.
- $\text{C}_4\text{H}_5\text{N}_2\text{S}_2$, from diguanide and carbon disulphide (RACKMANN), A., i, 827.
- $\text{C}_4\text{H}_5\text{OS}$, from methyl chlorothiocarbonate and magnesium methyl iodide (DELEPINE), A., i, 612.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}_7$, from triazomethylcarbimide and ammonia (FORSTER and MÜLLER), T., 1065.
- $\text{C}_4\text{H}_5\text{O}_2\text{Cl}_2\text{Hg}$, from mercury chloro-acetylde, mercuric chloride and sodium acetate (HOFMANN and KIRMREUTHER), A., i, 17.
- $\text{C}_4\text{H}_5\text{O}_2$, from isovaleraldehyde and ozone (HARRIES and KOETSCHAL), A., i, 607.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}$, from Δ -glutamic acid (ABDERHALDEN and KATZSCHN), A., i, 769.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}_3$, from triazomethylcarbimide and water (FORSTER and MÜLLER), T., 1063.
- $\text{C}_4\text{H}_5\text{Cl}_{12}$, from action of silent electric discharge on chloroform (LOSANTSCHN), A., i, 1.
- $\text{C}_4\text{H}_5\text{ON}_6$, from 7-hydroxy-5-methyl-1:2:1:9-benzotetrazole and hydrazine (BRILOW and HAAS), A., i, 568.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}_6$, from nitrosodiacetone-senckiaurazide (RUPE and KESLER), A., i, 16.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}_2\text{HgNa}$, from 4-imino-2,6-diketodihydropyrimidine-3-acetic acid and mercuric oxide (FABRIEN-FABRIEN VORM. F. BAYER & Co), A., i, 804.
- $\text{C}_4\text{H}_5\text{O}_2$, from heptaldehyde, ozone, and ethyl chloride (HARRIES and KOETSCHAL), A., i, 607.
- $\text{C}_4\text{H}_5\text{O}_2\text{I}$, from α -dimethylglutamic acid and phosphorus pentachloride (FEIST and REIER), A., i, 10.
- $\text{C}_4\text{H}_5\text{O}_2\text{N}$, from α -aminoglutaric acid, aurichloride of (ENGELAND), A., i, 843.
- $\text{C}_4\text{H}_5\text{O}_2\text{SHgNa}$, from hydroxymercurybenzoic anhydride and sodium sulphite (SCHÖZLER and SCHRAUTH), A., i, 460.
- $\text{C}_4\text{H}_5\text{O}_2$, from octaldehyde and ozone (HARRIES and KOETSCHAL), A., i, 607.

- Substance, $C_8H_{17}N$** , reduction product of η -chloro-octylamine and its salts (GABRIEL), A., i, 229.
- $C_8H_9O_2N_3$, from aniline and nitroacetonitrile (STEINKOPF, BOHRMANN, GRUNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 307.
- $C_{10}H_{10}O_2N_2$, from phenyltriazomethyl-carbamide and sodium carbonate (FORSTER and MÜLLER), T., 1065.
- $C_{10}H_{10}O_2N_4$, from 4:5-diamino-2:6-di-keto-1:3-dimethylpyrimidine (FARBENFABRIKEN VOHM, F. BAYER & Co.), A., i, 79.
- $C_8H_{11}O_2N_2$, from acetonecyanohydrin and hydrogen chloride (ULTEE), A., i, 15.
- $C_8H_5ON_2K$, from p -triazobenzaldehyde and potassium cyanide (FORSTER and JUDD), T., 260.
- $C_8H_7O_3$, from nonaldehyde and ozone (HARRIES and KOETSCHAU), A., i, 607.
- $C_8H_{11}O_2$, additive compound of quinol and acetone (SCHMIDLIN and LANG), A., i, 837.
- $C_8H_7O_3$, additive product of catechol and acetone (SCHMIDLIN and LANG), A., i, 837.
- $C_8H_{12}O_7$, from the interaction of ethyl malonate, sodium ethoxide, and iodine (KOMNENOS), A., i, 542.
- $C_8H_{12}O_9$, from oxidation of 1:3-dimethyl-5-methylene- Δ^2 -cyclohexene (ATWERS and PETERS), A., i, 826.
- $C_8H_5O_2N_2$, from 1-chloro-2:4-dinitrobenzene and sodioacetone (REITZENSTEIN and STAMM), A., ii, 358.
- $C_8H_5OS_2$, from acetophenone and carbon disulphide, and its derivatives (KELBER), A., i, 391.
- $C_8H_{11}O_4N$, from coal tar (SCHULTZ and SZÉKELY), A., i, 725.
- $C_9H_{11}O_2N_3$, from α -toluidine and nitroacetonitrile (STEINKOPF, BOHRMANN, GRUNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 307.
- $C_8H_{17}O_2N$, from α -aminoglutaric acid, auri-chloride of (ENGELAND), A., i, 843.
- $C_{10}H_{12}O$, from polymeric of crotonaldehyde (DELÉPINÉ), A., i, 219.
- $C_{10}H_{18}Cl_2$, from isothylene (KONDAKOFF and SKWORZOFF), A., i, 755.
- $C_{10}H_8ON_2$, from quinoline and cyanogen bromide (v. BRAUN), A., i, 189.
- Substance, $C_{10}H_2O_2N_4$** , from α -methazonic anhydride (STEINKOPF, BOHRMANN, GRUNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 308.
- $C_{10}H_{11}O_2N_3$, from methyl 1-phenyl-5-triazolone-4-carboxylate and alcoholic hydrogen sulphide (DIMROTH, ARKELIN, BRAUN, FESTER, and MERCKLE), A., i, 519.
- $C_{10}H_7O_2N_3$, from 4-keto-2-benzyl-4:5-dihydroglyoxaline and water (FINGER and ZER), A., i, 591.
- $C_{10}H_{12}O_2N_3$, from m -xylydine and nitroacetonitrile (STEINKOPF, BOHRMANN, GRUNUPP, KIRCHHOFF, JÜRGENS, and BENEDEK), A., i, 307.
- $C_{10}H_7O_2N_3$, isomeride of α -limonene-hydroxylamineoxime (CUSMANN), A., i, 686.
- $C_{10}H_{20}O_2N_2Cl_2$, from isomeride of α -limonenehydroxylamineoxime (CUSMANN), A., i, 686.
- $C_{11}H_{13}O_3$, from ethylmethylacetonedicarboxylate (FEIST and POMME), A., i, 9.
- $C_{11}H_9O_2N_3$, from pyridine and 1:3-dichloro 4:6 dinitrobenzene, salts of (ZINCKE and WEISFENNING), A., i, 585.
- $C_{11}H_{15}O_2N$, from action of sodium hydride on cyanacetone (CLARKE and LAPWORTH), T., 15.
- $C_{11}H_{20}O_2N_3$, from 4-methylamino-1:2:2:4-dimethyl-5-pyrrolidone and ethylene oxide (KOH and BUN), A., i, 137.
- $C_{11}H_7O_2S_2$, from dimethyl ether of $C_4H_5OS_2$ (KELBER), A., i, 391.
- $C_{11}H_7O_2HS_2$, from dimethyl ether of $C_4H_5OS_2$ (KELBER), A., i, 391.
- $C_{12}H_{11}$, from action of silent electric discharge on benzene and hydrogen (LOSANTSCH), A., i, 2.
- $C_{12}H_7O$, from acenaphthenequinone, and its magnesium salts (KALLÉ & Co.), A., i, 752.
- $C_{12}H_7O_2$, additive compound of phenol and cyclohexanone (SCHMIDLIN and LANG), A., i, 837.
- $C_{12}H_7O_4$, additive compound of resorcinol and acetone (SCHMIDLIN and LANG), A., i, 837.
- $C_{12}H_{22}O$, from lauryl chloride by the action of heat (BISTEZZONI and LANZUING), A., i, 87.
- $C_{12}H_{20}O_2$, from polymeric of crotonaldehyde (DELÉPINÉ), A., i, 219.
- $C_{12}H_8O_2S_2$, from oxidation of diphenylene p disulphoxide (+ $2H_2O$), (HILDTICH), T., 2588.

- Substance, $C_{12}H_{19}O_2N_3$, from betaine, $C_2H_5O_2N_3$, and sodium hydroxide (ZINCKE), A., i, 556.
- $C_{12}H_{19}O_2N_3$, from the action of nitrous acid on ethyl 1-imino-hydrindene-2-carboxylate (MITCHELL and THORPE), T., 2272.
- $C_{12}H_{13}O_2N$, oxime from ethyl tetrahydrobenzenedicarboxylate (LEUCHS and THEODORESCU), A., i, 396.
- $C_{12}H_{11}O_2N_3$, oxime from the aldehydic ester, $C_{22}H_{29}O_{12}N$ (LEUCHS and THEODORESCU), A., i, 396.
- $C_{12}H_{19}O_2N_3$, from the action of nitrous acid on the β -condensation product of *m*-4-xyldine and acetaldehyde (JONES and WHITE), T., 642.
- $C_{12}H_{13}OI$, from phenoxyhexylene (DIONNEAU), A., i, 354.
- $C_{12}H_{13}O_2N_4$, from hexamethylene-tetramine and resorcinol (GRISKE-WITSCH-TROCHIMOWSKY), A., i, 103.
- $C_{12}H_{19}O_2N$, condensation product from acetonecyanohydrin and hydrogen chloride (ULIÉ), A., i, 15.
- $C_{12}H_{19}O_{12}N$, from the nitration of cellulose (CHANE and JOYCE), A., i, 364.
- $C_{12}H_{19}O_2N_2Na$, from oxidation of aniline-*p*-sulphonic acid (REIFENSTEIN), A., i, 703.
- $C_{12}H_{19}O_2$, from the condensation of cyclobutan-1,3-dione in the presence of quinoline (CHICK and WILMORE), T., 1993; P., 217.
- $C_{12}H_{12}O_4$, from oxypucedanin by the action of sulphuric acid (HERZOG and KROHN), A., i, 125.
- $C_{12}H_{12}N_2$, from dehydracetic acid (BENARY), A., i, 135.
- $C_{12}H_{14}O_3$ and its acetyl derivative and phenylmethane, from oxypucedanin (HERZOG and KROHN), A., i, 125.
- $C_{12}H_{19}O_2$, from α -cyclogeraniol (BOUVEAULT), A., i, 380.
- $C_{12}H_{13}O_2N_2$, from ethyl α -cyano- α -ketobutyrate phenylhydrazones (WISLICENUS and SILBERSTEIN), A., i, 539.
- $C_{12}H_{19}ON$, α - and β -isomerides from ψ -cavidine and acetaldehyde (JONES and WHITE), T., 643.
- $C_{12}H_{18}O_2N_2$, from 4-ethylamino-2:2:3-trimethyl-1-ethyl-5-pyrrolidone and ethylene oxide (KOH and BUM), A., i, 137.
- $C_{12}H_{19}O_2N_2S$ and its methyl ester (MAYER), A., i, 261.
- Substance, $C_2H_3O_3NI_3$, from di-iodotyrosine, methyl iodide and potassium hydroxide (WHEELER and JOHNS), A., i, 114.
- $C_{11}H_{12}O_6$, from extract of red clover flowers (POWER and SALWAY), T., 243; P., 29.
- $C_{11}H_{12}O_6$, from isogalloflavin trimethyl ether (HERZIG, ERDÖS, and RIZICKA), A., i, 676.
- $C_{11}H_{11}O_6$, from α -dimethylglutamic acid and phosphorus pentachloride, and its anilide and methyl hydrogen ester (FEIST and REUTER), A., i, 10.
- $C_{11}H_{12}ON_2$, from salicylideneaniline and potassium cyanide (ROHR and SCHÄTEL), A., i, 776.
- $C_{11}H_{19}O_2N_2$, from 4-keto-2-benzyl-4:5-dihydroglyoxaline (FINGER and ZEH), A., i, 591.
- $C_{11}H_{19}O_2N_2$, from ethyl 1-cyanocyclopropane-1-carboxylate (MITCHELL and THORPE), T., 1001.
- $C_{11}H_{14}O_2Br_2$, from $C_{11}H_{11}O_2$ and bromine (FEIST and REUTER), A., i, 10.
- $C_{11}H_{17}O_2N$, from *p*-ethoxyphenylmalonimide and its sodium derivative (PUTTI), A., i, 23.
- $C_{11}H_{11}O_2N_2Cl$, from nitrosobenzene and methyl 5-chloroanthranilate (FREUNDLICH), A., i, 446.
- $C_{11}H_{12}O_2NCl_2$, from carpine hydrochloride and chlorine (BARGER), T., 172; P., 53.
- $C_{11}H_{15}O_2NCl_2Sh$, from di-*p*-anisylamine and antimony pentachloride (WIELAND and WICKER), A., i, 243.
- $C_{11}H_{16}O_6$, from extract of red clover flowers and its acetyl derivative (POWER and SALWAY), T., 239; P., 20.
- $C_{11}H_{14}O_3$, condensation product of catechol and acetone (SCHMIDLIN and LANG), A., i, 837.
- $C_{11}H_{16}O_2$, from isogalloflavin trimethyl ether (HERZIG, ERDÖS, and RIZICKA), A., i, 677.
- $C_{11}H_{15}O_3$, additive compound of phenol and acetone (SCHMIDLIN and LANG), A., i, 837.
- $C_{11}H_{12}O$, from the essential oil of hyacinths (ENKLAAR), A., i, 123.
- $C_{11}H_{12}O_6$, from action of sodium methoxide on $C_{11}H_{11}O_5$ (FEIST and REUTER), A., i, 10.
- $C_{11}H_{12}O_6$, from rhizome of *Cimicifuga racemosa* (FINNEMORE), A., ii, 891.
- $C_{11}H_{12}O_6$, additive compound of acetone and pyrogallol (SCHMIDLIN and LANG), A., i, 837.

- Substance, $C_{15}H_{20}O$, from diethyl ketone and methyl iodide (HALLER and BAUER), A., i, 300.
- $C_{15}H_{19}O_2N$, from phenylhydroxylamine and benzoylacetalddehyde (ALESSANDRI), A., i, 753.
- $C_{10}H_{12}ONS$, from aniline and a substance from acetophenone (KELBER), A., i, 391.
- $C_{15}H_{15}ON_3S$, from 5-thion-1:4-diphenyltriazole (NIRDLINGER and ACREE), A., i, 786.
- $C_{15}H_{19}O_3N_3K_3$, from s-trinitrobenzene and potassium propoxide (BUSCH and KÜGEL), A., i, 474.
- $C_{17}H_{25}ONCl_2Fe$, ferrichloride of the additive compound of tropine and benzyl chloride (SCHOLTZ), A., i, 97.
- $C_{15}H_{15}O_2$, from extract of red clover flowers and its acetyl derivative (POWER and SALWAY), T., 236:P. 20.
- $C_{16}H_{18}O_9$, from isogalloflavin trimethyl ether (HERZIG, ERDÖS, and RUZICKA), A., i, 678.
- $C_{16}H_{20}O$, from action of silent electric discharge on ethylene (LOSANTICH), A., i, 1.
- $C_{16}H_{12}O_2S_2$, from oxidation of "thio-indigo" (DANAÏLA), A., i, 411.
- $C_{16}H_{12}O_2S_2$, from oxidation of "thio-indigo" (DANAÏLA), A., i, 411.
- $C_{16}H_{12}O_2S_2$, from oxidation of "thio-indigo" (DANAÏLA), A., i, 411.
- $C_{16}H_{17}O_2N_3$, from picryl- α -naphthylamine and silver oxide (BUSCH and KÜGEL), A., i, 473.
- $C_{16}H_{11}O_7N_3$, from 3:5-dinitro-4-hydroxybenzoic acid and quinoline (MORGENSTERN), A., i, 483.
- $C_{16}H_{15}O_2N$, from safrole and nitrosobenzene, 2 isomerides (ANGELL, ALESSANDRI, and PEGNA), A., i, 552.
- $C_{16}H_{15}O_2N$, from chrysopaenic acid methyl ether and ammonia (+ $\frac{1}{2}H_2O$) (OSTERLE and JOHANN), A., i, 860.
- $C_{16}H_{17}O_3N_3$, from dinitrophenyldipyridinium dichloride and alkali, and its salts (ZINCKE and WEISFENNING), A., i, 585.
- $C_{17}H_{21}O_2N$, from dimethylketen and benzylidenemethylamine (STAUDINGER, KLEFFER, and KOEHL), A., i, 588.
- $C_{16}H_{21}O_8P$, from pierotin and phosphorus pentachloride (HORMANN), A., i, 577.
- $C_{18}H_{14}ON_2S$, condensation product of 3-oxyl-1-thionaphthen with p -nitrosodimethylaniline (BADISCHE ANILIN- & SODAFABRIK), A., i, 60.
- Substance, $C_{16}H_{10}O_4N_2S_2Na_2$, from 1-naphthol-4-sulphonic acid, phenylhydrazine and sodium hydrogen sulphite (BUTCHER and SONNENBERG), A., i, 145.
- $C_{17}H_{16}N_2$, from interaction of magnesium phenyl bromide and 3:3-dimethylindoline-2-carboxylonitrile, and its oxime and p -nitrophenylhydrazine (PLANCHER and GEMELLI), A., i, 53.
- $C_{17}H_{16}O_2N_2$, from 3:5-dinitro-4-hydroxybenzoic acid and naphthalene (MORGENSTERN), A., i, 482.
- $C_{17}H_{17}O_2Br_2$, from the reduction of β -bromocarmine (ROHDE and DORMEIER), A., i, 492.
- $C_{17}H_{22}O_2N_2$, from α -leucyl-L-tryptophan (FISCHER), A., i, 22.
- $C_{17}H_{26}O_2Cl_4$, from fatty acids in cod liver oil (HEIDESCHKA and RHEINBERGER), A., i, 297.
- $C_{17}H_{19}O_2N_2Cl$, from picryl chloride and methyl- α -naphthylamine (BUSCH and KÜGEL), A., i, 473.
- $C_{17}H_{14}O_2N_2S_2$, from immedial-indone (FRANK), T., 2045; P., 218.
- $C_{17}H_{19}N_2Cl_2Hg_2$, from dinitrophenylpyridinium chloride and p -aminophenyl mercuriacetate (REITZENSTEIN and STAMM), A., i, 313.
- $C_{17}H_{22}O_2Cl_4$, from fatty acids of cod liver oil (HEIDESCHKA and RHEINBERGER), A., i, 297.
- $C_{17}H_{17}O_2BrMg$, from action of magnesium on p -tolyl ethyl ketone and allyl bromide (GRISHKEWITSCH-TROCHIMOVSKY), A., i, 109.
- $C_{17}H_{19}ON_2Cl_2Hg_2$, from dinitrophenylpyridinium chloride and p -aminophenyl mercuriacetate (REITZENSTEIN and STAMM), A., i, 313.
- $C_{18}H_{20}O_8$, from kermesic acid and hydriodic acid (DINBOOTH), A., i, 458.
- $C_{18}H_{16}O_6$, from 3-hydroxymethylfluorene (KEHRMANN and JONES), A., i, 409.
- $C_{18}H_{20}O_9$, from isogalloflavin trimethyl ether (HERZIG, ERDÖS, and RUZICKA), A., i, 678.
- $C_{19}H_{21}O_2N$, from ester, $C_{20}H_{23}O_2N$ (WILLGROEDT and MAFFEZOLI), A., i, 679.
- $C_{18}H_{17}O_2S_2$, from $C_{16}H_{12}O_2S_2$ and ammonium persulphate (KELBER), A., i, 391.
- $C_{19}H_{14}O_2N_2$, from isobenzylglyoxalidone and sodium hydroxide (FINGER and ZEN), A., i, 591.
- $C_{18}H_{16}O_2N_2$, from ethylengonol and nitrosobenzene (ANGELL, ALESSANDRI, and PEGNA), A., i, 553.

- Substance, $C_{10}H_{12}O_2N_2$, from hexamethylenetetramine and catechol (GRISHKEWITSCH-TROCHIMOWSKY), A., i, 108.
- $C_{16}H_{12}O_4$, from 3-phenylpyrazoisocoumarazone and resorcinol (MICHAELIS and LEO), A., i, 516.
- $C_{18}H_{14}O_2$, from 3-methylpyrazoisocoumarazone and resorcinol (MICHAELIS and LEO), A., i, 516.
- $C_{19}H_{28}O_{10}$, from biliary acids (PREGL), A., i, 321.
- $C_{10}H_{14}O_2N_2$, from 3:5-dinitro-4-hydroxybenzoic acid and acenaphthene (MORGENTERN), A., i, 482.
- $C_{19}H_{16}O_4Cl_2$, from 2:5-dihydroxytriphenylcarbinol (V. BAeyer, AICKELIN, DIEHL, HALLENSLEDEN, and HESS), A., i, 219.
- $C_{18}H_{12}O_2N_2$, from *p*-benzoquinone and diaminodiphenylmethane (SIEGMUND), A., 749.
- $C_{19}H_{12}N_2ClHg$, from 3-mercury-*p*-toluidine and dinitrophenylpyridinium chloride (REITZENSTEIN and STAMM), A., i, 348.
- $C_{20}H_{20}O_2$, from methyl chloroformate and ostruthin (HEERZOG and KROHN), A., i, 125.
- $C_{20}H_{12}O_2$, from *Adenium Hoopkii* (PERROT and LEFRINCE), A., ii, 151.
- $C_{21}H_{12}O_4N_2$, azo-dye from ω -aminophthalanil (RIFFÉ and THIES), A., i, 73.
- $C_{21}H_{12}N_2S_2$, from diazotriphenylpyrrole (ANGELICO and LABISI), A., i, 445.
- $C_{20}H_{20}O_2Cl_2$, 2 isomerides from $\beta\beta$ -dichloro- $\alpha\gamma$ -dianisylidene-propylene and methyl alcohol (STRAUS, LITZ, and HUSSY), A., i, 564.
- $C_{20}H_{12}O_2N_2$, from 1:3-dioximino-2-cyclohexanone with sodium ethoxide and benzoyl chloride (BOESCHKE), A., i, 178.
- $C_{21}H_{12}O_2N_2S_4$, from 3-cyano-2:4-diketo-5-benzylidenetetrahydrothiophen and barium hydroxide (BENARY), A., i, 580.
- $C_{25}H_{30}O_2N_2S + 2H_2O$, from acetylguanamine acetate and orange II (RAUBKEGER), A., i, 761.
- $C_{21}H_{12}O_2NS$, from ψ -codeinone and ethyl mercaptan (PSCHORR and KRECH), A., i, 423.
- $C_{20}H_{20}O_2NI$, from methyl iodide and a betaine from β -ethylthiocodide (PSCHORR and KRECH), A., i, 423.
- $C_{21}H_{27}O_2NS$, betaine of substance from β -ethylthiocodide (PSCHORR and KRECH), A., i, 422.
- Substance, $C_{21}H_{27}O_2NS$, from 3-ethylthiocodide (PSCHORR and KRECH), A., i, 422.
- $C_{20}H_{20}O_2NS$, from β -methylthiocodide and ethyl mercaptan (PSCHORR and KRECH), A., i, 422.
- $C_{21}H_{19}O_{19}AsNa_3$, from trisodium-arsenate and sulphosalicylic acid (BARTHE), A., i, 262.
- $C_{20}H_{27}O_2N_2ClHg$, from dinitrophenylpyridinium chloride and *p*-aminophenyl mercaptacetate (REITZENSTEIN and STAMM), A., i, 348.
- $C_{21}H_{27}O_2NIS$, from methyl iodide and β -ethylthiocodide, and its derivatives (PSCHORR and KRECH), A., i, 422.
- $C_{22}H_{12}O_8$, from the condensation of phenanthraquinone with ethylacetoacetate (RICHARDS), T., 1460; P., 195.
- $C_{22}H_{12}O_8$, from *p*-benzoquinone and methyl *p*-aminobenzoate (SIEGMUND), A., i, 749.
- $C_{22}H_{12}O_2N$, from ω -amino- $\alpha\alpha$ -dihydroxyacetophenone (TETTS), T., 2515.
- $C_{21}H_{20}O_2N$, from dimethylketen and benzylidenenaphthylamine (STADINGER, KLEVER, and KOBER), A., i, 588.
- $C_{22}H_{12}O_2N$, from oxidation of β -isobutyrylbenzylamine- β -phenyl- $\alpha\alpha$ -dimethylpropionic acid (STADINGER, KLEVER, and KOBER), A., i, 587.
- $C_{22}H_{12}O_{12}N$, acetyl derivative of the product from nitration of cellulose (CRANE and JOYCE), A., i, 364.
- $C_{22}H_{12}O_2NSNa$, from 1-amino-2-naphthol-4-sulphonic acid, phenylhydrazine and sodium hydrogen sulphite (BUCHERER and SONNENBERG), A., i, 145.
- $C_{22}H_{12}O_{12}$, and its acetyl derivative, from the potassium derivative of rhein (OESTERLE and RIAT), A., i, 126.
- $C_{21}H_{12}O_2N_2$, from 3:5-dinitro-4-hydroxybenzoic acid and pyrene (MORGENTERN), A., i, 482.
- $C_{22}H_{12}O_2NS$, phenacyl derivative of compound of $C_9H_6ON_2$ and aniline (KELBER), A., i, 391.
- $C_{22}H_{17}O_4N_2Br$, from brucine (MOSELER), A., i, 275.
- $C_{21}H_{12}$, from action of silent electric discharge on benzene (LOSANTSCH), A., i, 2.
- $C_{22}H_{14}O_4$, from acenaphthenequinone and its derivatives (KALLÉ & Co.), A., i, 752.

- Substance, $C_{24}H_{16}O_{21}$, from reduction of 5:12-dihydroxy-11-phenonaphthalenequinone, and its acetyl derivative (VOSWINCKEL and DE WEEERTH), A., i, 50.
- $C_{24}H_{16}O_{10}$, tetra-acetyl derivative of $C_{24}H_{16}O_8$ obtained in the preparation of chloroacetoacetic acid (VOSWINCKEL), A., i, 43.
- $C_{24}H_{16}O_8$, from oxidation of elateric acid (MOORE), T., 1804; P., 215.
- $C_{24}H_{20}ON_2$, from tetramethyldiaminotriphenylmethane-*o*-carboxylic acid (GUYOT and HALLER), A., i, 256.
- $C_{24}H_{20}O_2Cl_2$, from ester $C_{20}H_{20}O_6$ (GUTHZEIT and HARTMANN), A., i, 389.
- $C_{24}H_{20}O_2Cl_2$, from ester $C_{20}H_{20}O_6$ (GUTHZEIT and HARTMANN), A., i, 388.
- $C_{24}H_{20}O_2Br_2$, from ester $C_{20}H_{20}O_6$ (GUTHZEIT and HARTMANN), A., i, 388.
- $C_{24}H_{24}N_8Cl$, azo-dye from 2:4-dimethylpyrrole (MARCHELEWSKI and ROBEL), A., i, 206.
- $C_{24}H_{20}O_2N_2$, from quinine- β -ethiodide and Grignard's reagent (FRIED and MAYER), A., i, 132.
- $C_{25}H_{20}O_2N_2$, base from 3:6-diacylamino-9-phenylxanthonium chloride (KEHRMANN and DENGLE), A., i, 406.
- $C_{25}H_{20}O_2N_2$, from acetylacetone and diphenylmethanedimethyldihydrazine (v. BRAUN), A., i, 524.
- $C_{25}H_{20}O_2N_2Cl$, benzoyl derivative of a red acid from methyl 5-chloroanthranilate and nitrosobenzene (FREUNDLER), A., i, 446.
- $C_{25}H_{20}O_2N_2S_2$, from biguanidesulphate and crystal poncean (RADLEBERGER), A., i, 760.
- $C_{25}H_{20}O_2N_2$, from the action of *p*-triazobenzaldehyde on camphoryl- ϕ -semicarbazide (FORSTER and JUD), T., 261.
- $C_{25}H_{20}O_2N_2ClHg_2$, from dinitrophenylpyridinium chloride and *p*-aminophenyl mercaptacetate (REITZENSTEIN and STAMM), A., i, 348.
- $C_{26}H_{20}O_2$, from diphenyl-naphthylallene-carboxylic acid and acetic acid (LAPWORTH and WECHSLER), T., 47.
- $C_{26}H_{24}O_2$, from action of silent electric discharge on ethylene (LOSANITSCH), A., i, 1.
- $C_{26}H_{20}O_2N_2$, from anthraquinone-2:3-dicarboxylic anhydride, quinaldine and zinc chloride (WILLGERODT and MAFFEZZOLI), A., i, 679.
- Substance, $C_{26}H_{16}O_{15}N_4$, from 3:5-dinitro-4-hydroxybenzoic acid and diphenylene oxide (MORGENSTERN), A., i, 482.
- $C_{27}H_{18}O_{14}N_4$, from 3:5-dinitro-4-hydroxybenzoic acid and fluorene (MORGENSTERN), A., i, 482.
- $C_{27}H_{16}O_8$, from 2-benzoyl-3:4-dimethoxybenzoic acid (FALTIS), A., i, 698.
- $C_{28}H_{24}$, from action of silent electric discharge on benzene and hydrogen (LOSANITSCH), A., i, 72.
- $C_{28}H_{16}O_2$, from anthraquinone (KINZL-BEGER & Co.), A., i, 752.
- $C_{28}H_{12}O_{11}N_4$, from 3:5-dinitro-4-hydroxybenzoic acid and phenanthrene (MORGENSTERN), A., i, 483.
- $C_{28}H_{10}O_2N_2$, from 3-phenylpyrazolocoumarazone and phenol (MICHAELIS and LEO), A., i, 516.
- $C_{28}H_{10}O_2N_2$, from oxidation of diauisidine (REITZENSTEIN), A., i, 703.
- $C_{28}H_{12}O_6N_6S_2Na_2$, from 1-benzencazo-2-naphthol 6 sulphonic acid, phenylhydrazine, and sodium hydrogen sulphite (BUCHERER and SONNENBURG), A., i, 146.
- $C_{28}H_{10}O_6Br_2$, from ester $C_{26}H_{10}O_4$ (GUTHZEIT and HARTMANN), A., i, 388.
- $C_{29}H_{12}O_8N_8$, from hexamethylenetetramine and pyrogallol (GRISHKE-WITSCH-TROCHIMOWSKI), A., i, 108.
- $C_{29}H_{22}N_4$, from benzaldehyde and diphenylmethanedithyldihydrazine (v. BRAUN), A., i, 525.
- $C_{29}H_{16}O_{14}N_4$, from 3:5-dinitro-4-hydroxybenzoic acid and retene (MORGENSTERN), A., i, 482.
- $C_{29}H_{10}ON_4$, from 3-phenylpyrazolocoumarazone and dimethylaniline (MICHAELIS and LEO), A., i, 516.
- $C_{29}H_{12}O_6N_4$, from benzoylation of *m*- and *p*-aminobenzoic acid in pyridine, and its salts (HEILER and TISCHNER), A., i, 779.
- $C_{29}H_{20}O_2N_2$, from benzoylacetone and diphenylmethanedimethyldihydrazine (v. BRAUN), A., i, 524.
- $C_{29}H_{16}O_2N_2$, from anisaldehyde and diphenylmethanedithyldihydrazine (v. BRAUN), A., i, 525.
- $C_{31}H_{20}O_2$, from phenyl β -ethoxystyryl ketone (REYNOLDS), A., i, 858.
- $C_{31}H_{20}O_4N_2$, from *p*-nitrobenzaldehyde and sodium camphor (WOOTTON), T., 411.
- $C_{31}H_{20}O_2N_2S_2$, from biguanide sulphate and orange II (RADLEBERGER), A., i, 760.

- Substance**, $C_{15}H_{21}O_6N_3$, from benzoylation of *p*-aminophenylacetic acid in pyridine (HELLER and TISCHNER), A., i, 770.
- $C_{20}H_{31}O_{11}Cl_3$, from oxypencedanin and hydrogen chloride (HERZOG and KROHN), A., i, 125.
- $C_{40}H_{71}Br_{20}$, from lycopene (WILLSTÄTTER and ESCHER), A., i, 331.
- $C_{40}H_{56}I_2$, from carotene (WILLSTÄTTER and ESCHER), A., i, 331.
- $C_{11}H_{10}O_2N_4$, from oxidation of oximinotriphenylpyrrole (ANGELICO and LABINI), A., i, 427.
- $C_{20}H_{24}O_6N_2$, from *p*-benzoquinone and diaminosilbene (SIEGMUND), A., i, 749.
- $C_4H_{12}O_4N_2Br$, from brucine and cyanogen bromide (MOSSLER), A., i, 275.
- $C_{40}H_{56}O_4N_2Cl_3Br$, from brucine and cyanogen bromide (MOSSLER), A., i, 275.
- $C_{20}H_{30}O_{10}$, from "bromoacetocellobiose" and silver carbonate (FISCHER and ZEMPLEN), A., i, 718.
- $C_{20}H_{30}O_{10}$, from "bromoacetolactose" and silver carbonate (FISCHER and FISCHER), A., i, 716.
- Succinamide**, *d*-nitro-derivative of (TINGLE and BURKE), A., i, 21.
- Succinic acid**, sodium salts of (MARSHALL and BAIN), T., 1074; P., 114.
- Succinic acid**, *di*bromo-, pyridine salts of (PFEIFFER, LANGENBURG, and BIRENCKWEG), A., i, 878.
- Succinic anhydride**, rate of hydration of (RIVETT and SIDGWICK), T., 1677; P., 200.
- Succinylidguanide**, and its salts (RICKMANN), A., i, 896.
- Succinylguaninopropionic acid** (FARBEN-FABRIKEN VORM. F. BAYER & Co.), A., i, 79.
- Succinylphenylimide**, *m*-nitro- (TINGLE and BURKE), A., i, 21.
- Succinylthio-*p*-toluamide** (MARSET), A., i, 667.
- Sucrose** (*сахароза*, *cane sugar*), formation of, in seeds, influence of potassium salts on the (DE PLATO), A., ii, 742.
- contraction occurring on the solution of, in water (FOUGET), A., i, 96; (DÉRIDHEL), A., i, 223.
- vapour pressure of aqueous solutions, of (KRAUSKOPF), A., ii, 688.
- change of rotation of, in presence of alkaline aranyl solutions (GROSSMANN and ROBINSON), A., i, 223.
- influence of salts on the rotatory power of (WASHBURN), A., i, 390.
- Sucrose**, inversion of (HUDSON), A., i, 797; ii, 702; (HUDSON and PAUL), A., i, 601, 797, 798.
- theory of the inversion of (MEYER), A., ii, 493.
- influence of boric acid on the inversion of (ARAFURU), A., i, 653.
- fate of, in animals (MENDEL and KLEINRU), A., ii, 974.
- crystals, speed of dissolution at different faces of (GAILLARD), A., ii, 133.
- production of slime from, by means of viscoseaccharase (BEYERLING), A., i, 460.
- reactions of (REICHARD), A., ii, 1117.
- detection of, in wines (ROTHENETSER), A., ii, 463.
- polarimetric estimation of, in the presence of reducing sugars (LEFFLAND), A., ii, 1006.
- separation of lactose and (MAGAILLAN), A., ii, 163.
- Sucrosephosphoric acid** (NEUBERG and POLLAK), A., i, 157.
- Sucrosesulphuric acid**, barium and calcium salts of (NEUBERG and POLLAK), A., i, 610.
- Sugar**, production of, from amine-acids (RINGER and LUSK), A., ii, 227.
- conversion of cellulose into (OSER and WILKENING), A., i, 364.
- formation of, from fat, in phloridzin diabetes (LONMEL), A., ii, 793.
- spontaneous crystallisation of (FORQUET), A., ii, 193.
- destruction in animal organisms (VAN DERVELDE), A., ii, 141.
- absorption of, in the kidneys (NISHI), A., ii, 525.
- influence of, on the intestinal membrane (MAYERHOFFER and STEIN), A., ii, 974.
- oxidation of, in plant respiration (KOSYTSCHOFF), A., ii, 740.
- estimation of, volumetrically (RUFF and LEHMANN), A., ii, 163.
- estimation of, by reduction of colouring matters (WENDER), A., ii, 1116.
- estimation of, in urine (RAGG and BORNMANSSON), A., ii, 163; (LASSERMAICH and LINDHARD), A., ii, 905.
- Lang's method of estimating (ANDERSEN), A., ii, 757.
- colorimetric method of estimating (FRATTONI), A., ii, 757; (WACKER), A., ii, 306.
- in blood, estimation of (MOSE, LITKENS, and SANDEREN; MACKELAND FRANK), A., ii, 554, 1116; (MICHAELIS and ROWA), A., ii, 660.

- Sugar, estimation of, in the sugar beet, influence of optically active non-sugar material on the (ANDRĚK and STANĚK), A., ii, 463.
- Sugar, invert, estimation of, in sugar beet (URBAN), A., ii, 357.
- Sugars, kinetic studies in the (NĚMEČEK), A., i, 95.
- effect of, on solutions of salts (GLOVER), P., 298.
- the scission of (LÖB and PULVERMACHER), A., i, 95.
- and synthesis of, from formaldehyde (LÖB and PULVERMACHER), A., i, 609.
- enzymic condensation of (PANTANELLI and FAURE), A., i, 450.
- anilides of, constitution and mutarotation of (LYVINE and McNICOLL), T., 1449; P., 195.
- Sugars, reducing, precipitation of, by lead acetate (PELLET), A., ii, 462.
- Sugar beet, estimation of invert-sugar in (URBAN), A., ii, 357.
- Sugar group, dissociation processes in the (NEF), A., i, 711.
- Sugar solutions, fermented, the influence of, on the respiration of wheat seedlings (KOSTYTSHEFF), A., ii, 148.
- reactions of (NEUBERG), A., ii, 447.
- action of ultra-violet light on (BERTHELOT and GAUDICHON), A., ii, 813.
- Suginene and its dihydrobromide and dihydriodide (KIMURA), A., i, 53.
- Sulphides. See under Sulphur.
- 2:5-Sulphido-1:2:3-trimethylpyrazole and 4-bromo-, and their derivatives (MICHAELIS and LACHWITZ), A., i, 641.
- Sulphinic acids, aromatic, intermolecular condensation of (HILDEITCH), T., 2579; P., 294.
- Sulphonyldibenzoic acid (2:2'-dicarboxydiphenyl sulphoxide), and its methyl and ethyl esters (MAYER), A., i, 281.
- Sulphoanilindiphenylmethane, amino-*p*-nitro-, di-*p*-amino-, and di-*p*-nitro-, sodium salts of (STRAUS and BORMANN), A., i, 282.
- Sulphobenzeneazocacethydraxide, sodium salt of (DIMROTH and DE MONTMOLLIN), A., i, 899.
- p*-Sulphobenzeneazo-*p*-methoxyphenol, sodium salt and benzoate (KAUFFMANN and FRITZ), A., i, 377.
- 6-Sulpho-β-naphthol-1-azo-*γ*-hydroxybenzoic acid as a new indicator (MILLET), A., ii, 995.
- Sulphonyl chlorides, aromatic, electrolytic reduction of (FICHTER and TAMM), A., i, 835.
- 5-Sulphonyl-1-aldehyde-3-benzoic acid, 2-hydroxy- (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 321.
- 4-Sulphophenyl *o*-tolyl ether, 2-amino-, and its barium salt (FARBENFABRIKEN VORM. F. BAYER & Co.), A., i, 374.
- Bz-Sulphoquinolinecarboxylic acids (EDINGER and BÜHLER), A., i, 64.
- Sulphosalicylic acid, quinoline salt (ZERNIKER), A., i, 586.
- Sulphoxanthinedicarboxylic acid, and its copper salt (ERSTEIN), A., i, 117.
- Sulphoxides, basic properties and tautomerism of (FROMM and RAIZISS), A., i, 554.
- Sulphoxides, hydroxy-, aromatic (GAZDAR and SMILES), T., 2248; P., 253.
- Sulphur, absorption spectra of the vapour of, in relation to its molecular complexity (GRAHAM), A., ii, 1015.
- pseudo-systems of, nomenclature of (KRUYP), A., ii, 400.
- boiling-point of (CALENDAR and MOSE), A., ii, 28.
- dissociation isotherms of (PREUNER and SCHUPP), A., ii, 118.
- action of hydrogen on, in the presence of another element (PÉLABON), A., ii, 119.
- slow combustion of (BONNSTEIN and KARO), A., ii, 1051.
- mutual behaviour of tellurium and (JAEGER), A., ii, 497.
- the system, nickel and (BOHRNMANN), A., ii, 1072.
- behaviour of, in the animal organism (KONSCHEG), A., ii, 637.
- colloidal, preparation of (v. WEIMARN and MALINSHEFF), A., ii, 941.
- colloidal and silver sulphate, velocity of the reaction between (RAFFO and PIERONI), A., ii, 859.
- compounds, colour and absorption spectra of (PURVIS, JONES, and TASKER), T., 2287; P., 234.
- compounds of, with phosphorus (STOCK and RUDOLPH), A., ii, 200; (STOCK and HERSCOVICI), A., ii, 200, 499.
- action of, on magnesium cyclohexyl chloride (MAILHE and MURAT), A., i, 374.
- action, of haloid derivatives of, on organomagnesium compounds (FERBARIO and VINAY), A., i, 604.
- elastic, resembling caoutchouc (v. WEIMARN), A., ii, 496, 603.
- fused, solidification of (WIGAND), A., ii, 602.
- "insoluble," solubility of (WIGAND), A., ii, 1055.

Sulphur monochloride, action of hydrogen on, under the influence of the electric discharge (BESSON and FOURNIER), A., ii, 705.
 chloride, action of organo-magnesium compounds on (STRECKER), A., i, 532.
Thionyl chloride, action of hydrogen on, under the influence of the electric discharge (BESSON and FOURNIER), A., ii, 705.
 action of, on mercury and mercuric oxide (NORTH), A., ii, 296.
 action of magnesium organic compounds on (STRECKER; GRIGNARD and ZOERN), A., i, 532.
 interaction of, with phenyl mercaptan (TASKE and JONES), P., 234.
 action of, on benzoic acid (STOLLÉ), A., i, 737.
Sulphuryl chloride, action of, on mercury and mercuric oxide (NORTH), A., ii, 296.
Sulphur oxides, per-oxidation of, by ultra-violet light (BERTHELOT and GAUCHECHON), A., ii, 606.
 dioxide, refraction and dispersion of (CUTHBERTSON and CUTHBERTSON), A., i, 85.
 electrical purification and conductivity of (CARVALLO), A., ii, 1026.
 absorption of, by caoutchouc and by wool (RAYCHLER), A., ii, 272.
 the system, chlorine and (SMITS and DE MOOR), A., ii, 1049.
 disappearance of, from wines (HUBERT), A., ii, 152.
 trioxide, estimation of, in fuming sulphuric acid (VERNON), A., ii, 803.
Sulphides, metallic, action of liquids which dissolve sulphur on (JORDIS and SCHWEIZER), A., ii, 405.
 organic, action of sulphur and ammonia on (HOLMBERG), A., i, 150.
 isomeric platinum compounds of (TSCHUGAEFF and SUBBOTIN), A., i, 354.
Sulphurous acid, in white wines (GAUTHELET), A., ii, 734.
 electrolytic oxidation of, in aqueous solution (FISHER and DELMARCEL), A., ii, 603.
 as an etching agent (HILFERT and CULVER-GRAFF), A., ii, 900.
 esters of, action of organo-magnesium compounds on (STRECKER), A., i, 532.

Sulphur :—
Sulphurous acid, detection and estimation of, in wines (MATHIEU), A., ii, 650.
 estimation of (FOUQUET), A., ii, 344.
 estimation of, in wines (CAZENAVE), A., ii, 544.
Sulphites, constitution of (BAYBIGNY), A., ii, 497.
Sulphuric acid, photochemistry of (COHEN and BECKER), A., ii, 218.
 ionisation of (NOYES and STEWART), A., ii, 937.
 ionisation of, in mixtures of alcohol and water (KREMANN and BIASERT), A., ii, 603.
 absolute, condition of substances in (BERGUS), A., ii, 398; (ODD and SCANDOLA), A., ii, 1035.
 and mixtures of, with water, solubility of gases in (BOHR), A., ii, 198.
 and alcohol, equilibrium in the reaction between (KREMANN), A., ii, 700.
 ammonium sulphate, and water at 30°, the system (VAN DORP), A., ii, 698.
 lithium sulphate and water, at 30°, the system (VAN DORP), A., ii, 698.
 action of potassium chlorate on concentrated (SMITH), P., 124.
 and ether, physical properties of mixtures of (POUND), P., 341.
 and hydrochloric acid, use of electrolytic chlorine for the production of (CORRADORO), A., ii, 197.
 amides of (EPHRAIM and GEBEWITSCH), A., ii, 198.
 detection of, in wines (HUBERT and ALBA), A., ii, 651.
 estimation of, in pyrites (HYBBRECHTS), A., ii, 545.
 estimation of, gravimetric, in presence of alkali metals (KATO and NONA), A., ii, 895.
 estimation of, by the "benzidine process," in the presence of chromium (v. KNOBE), A., ii, 545.
 volumetric estimation of (HOLLIGER), A., ii, 234.
 and sulphur dioxide, estimation of, in the gases of sulphur furnaces (PILLER), A., ii, 69.
 estimation of nitric compounds in (LEO), A., ii, 711.
 fuming, estimation of sulphur dioxide in (VERNON), A., ii, 804.

Sulphur:—

- Sulphates**, acid (D'ANS), A., ii, 125;
(D'ANS and FRETSCHER), A., ii, 127.
anhydrous (CALCAGNI and MAN-
CINI), A., ii, 1064.
double, influence of substances in
solution on the crystal-habit of
(GERHART), A., ii, 276.
etheral, the origin of, in the
organism (SATO), A., ii, 58.
soluble, estimation of sulphur in
(ALLEN and JOHNSTON), A., ii,
650.
estimation of, as barium sulphate
(RUFFIN), A., ii, 1108.
volumetric estimation of, by the
barium chromate method (ROE-
MER), A., ii, 751.
Persulphuric acid, synthesis of
(D'ANS and FRIEDRICH), A., ii,
706.
dynamics of the decomposition of,
and its salts in aqueous solution
(GREEN and MASSON), T., 2083;
P., 231.
Persulphates, influence of, on the
estimation of hydrogen peroxide
with permanganate (FRIEND), P.,
88.
Dithionic acid and dithionates, estima-
tion of (BAUBIGNY), A., ii, 69.
Dithionates, constitution of (BAU-
BIGNY), A., ii, 497.
separation and purification of (BAU-
BIGNY), A., ii, 290.
Hypsulphites (BINZ and MARX), A.,
i, 711, 728.
Polythionio acids, analysis of (CASO-
LARI), A., ii, 997.
Sulphur, detection of small quantities
of, in inorganic and organic com-
pounds (DEUSSEN), A., ii, 750.
apparatus for the estimation of
(KLEINE), A., ii, 749; (PREUSS),
A., ii, 893.
estimation of, in iron and steel, appa-
ratus for (PREUSS), A., ii, 233, 1109.
estimation of, in graphite (CIBULKA),
A., ii, 749.
in molybdenum, tungsten and their
iron alloys (TRAUTMANN), A., ii,
543.
in pyrites (HUYBRECHTS), A., ii,
544; (ZEPETMAYR), A., ii, 802.
in alloys of tungsten, molybdenum,
and vanadium with iron (MÖLLER
and DIETHELM), A., ii, 1110.
in soluble sulphates (ALLEN and
JOHNSTON), A., ii, 650.
in organic substances (MARCUSSEON
and DÖSCHEK), A., ii, 543;
(SCHREIBER), A., ii, 594.

- Sulphur**, estimation of, in coal (PARR,
WHEELER, and BEROLZHEIMER), A.,
ii, 541.
used for agriculture, analysis of
(COLLIN), A., ii, 543.
Sulphur auratum, estimation of, in
rubber (FRANK and BIRKNER), A., ii,
241.
Sulphur compounds, thermochemical
investigations of (SVETOSLAVSKY),
A., ii, 187.
Sulphur organic compounds, spontane-
ously oxidisable with phosphorescence
(DELEPINE), A., i, 612.
Sulphuric and sulphurous acids. See
under Sulphur.
Sun, distribution of the ultimate rays in
the spectrum of (DE GRAMONT), A.,
ii, 85.
Superphosphates. See under Phos-
phorus.
Suprarenal gland, cortex of the (KAWA-
SHIMA), A., ii, 1038.
behaviour of the chromaffine substance
of, in hunger and under influence of
potassium iodide (VENULET and
DMITROWSKY), A., ii, 1038.
Suprarenine. See Adrenaline.
Surface tension, connexion of, with the
internal pressure and van der Waals'
constants a and b (TRAUBE), A., ii,
20.
measurement of (MAGINI), A., ii,
332.
and surface-energy (MILLS and McRAE),
A., ii, 932.
of aqueous solutions and Laplace's
constant (LEWIS), A., ii, 933.
effect of toxins and anti-toxins on
(BERTOLINI), A., ii, 987.
**Surface tensions of unsaturated organic
compounds** (GETMAN), A., ii, 832.
Sweat, occurrence of sebum in human
(EMBDEN and TACHAU), A., ii, 961.
Sylvestrene. See α -Carvestrene.
Synergism, from wheat (PALLADIN), A.,
i, 760.
Syntheses, asymmetric, by means of
enzymes (ROSENTHALER), A., i,
603.
organic, origin of the use of magnesium
in (BARBIER), A., ii, 303; (GRIG-
NARD), A., i, 466.
Systems, disperse, theory for obtaining
(v. WEIMARN), A., ii, 940.
condensation methods for the pre-
paration of (v. WEIMARN), A., ii,
399.
classification of (v. WEIMARN), A.,
ii, 834.
crystalline solid solutions as (WEI-
MARN), A., ii, 696.

T.

- Talc**, adsorption by (ROHLAND), A., ii, 615.
- Tallow**, Japan, unsaponifiable constituents of (MATTHEW and HEINTZ), A., i, 149.
- Tanacetone** (*β -thujone*) and its derivatives (THOMSON), T., 1502; P., 177.
- Tannin** (CAVAZZA), A., ii, 233; (TRUNKEL), A., i, 704.
molecular weight of (ILJIN), A., i, 762.
constitution of (NIERENSTEIN), A., i, 265.
discovery of the optical activity of (VON LIPPMAHN), A., i, 55.
action of zinc oxide on (ILJIN), A., i, 331.
fixing and staining, in plant tissues (VINSON), A., ii, 744.
estimation of, in catechu (VAN DORP and RODENBURG), A., ii, 167.
- Tannins** (NIERENSTEIN), A., i, 389.
- Tanning processes** (v. SCHROEDER), A., i, 129; (HERZOG and ROSENBERG), A., ii, 934.
- Tantalites**, analysis of (CHESNEAU), A., ii, 161.
- Tantalum**, occurrence of, in Western Australia (SIMPSON), A., ii, 1077.
atomic weight of (BALKE), A., ii, 962.
anodic behaviour of (KRESSNER), A., ii, 927.
halides of (VAN HAAGEN), A., ii, 619.
halide bases of (CHAPIN), A., ii, 303.
thallous fluoride (EPHRAIM and HEYMANN), A., ii, 38.
sulphide (BILTZ and KIRCHER), A., ii, 619.
- Bromotantalum hydroxide**, chloride, bromide, and iodide (CHAPIN), A., ii, 301.
- Tarelaic acid**. See Δ^5 -Elaidic acid.
- Tartaric acid**, inertia of crystallisation of, from mother liquors (CARLES), A., i, 360.
rotatory power of, in the presence of ammonium molybdate and sodium phosphate (MADENAU), A., ii, 915.
estimation of (BEY), A., ii, 662, 758.
- Tartaric acid**, aniline antimonyl salt (YVON), A., i, 163.
aniline arsenyl salt (YVON), A., i, 310.
molybdenum salts (QUINER), A., i, 218.
ethyl ester, rotation of (GROSSMANN), A., ii, 563.
- d* **Tartaric acid**, estimation of (KLING), A., ii, 359.
- z* **Tartaric acid**, ammonium hydrogen salt, preparation of (KLING), A., i, 651.
- Tartaric acids**, physiological action of (KARCZAG), A., ii, 434.
- Tartarodi-o**, *m*-, and *p*-bromoanilides (FRANKLAND and TWISS), T., 157.
- Tartarodi-o**, *m*-, and *p*-chloroanilides (FRANKLAND and TWISS), T., 159.
- Tartramide**, the influence of various substituents on the optical activity of (FRANKLAND and TWISS), T., 154; P., 5.
- Tartranilide**, *s-m*-dinitro- (TANGLE and BURKE), A., i, 22.
- Tartrates**, rotatory dispersion of coloured complex (GROSSMANN and LOER), A., ii, 372.
analysis of (CARLES), A., ii, 758.
- Tartronic acid**, methyl ester (FILIPPO), A., i, 298.
- Tartronodimethylamide** (FILIPPO), A., i, 298.
- Tautomerism**, mechanism of (TIZARD), P., 125.
- Tea**, estimation of caffeine in (BERGMANN), A., ii, 438.
- Teeth**, chemical investigation of (GASMAN), A., ii, 57.
- Tellurium**, atomic weight of (MAWK-WALD and FOZIK), A., ii, 601.
allotropy of (COHEN and KROENIG), A., ii, 199.
complexity of (FLINT), A., ii, 845.
colloidal, preparation of (v. WEIMANN and MALJISHEFF), A., ii, 941.
mutual behaviour of sulphur, and (JAEGER), A., ii, 497.
oxide, heat of formation of, and heat of combination of, with sodium oxide (MIXTER), A., ii, 355.
- Tellurium organic compounds** (LEDERER), A., i, 731.
- Tellurium**, estimation of, by means of silver (PERKINS), A., ii, 659.
- Temperature**. See under Thermochemistry.
- Tenebrio molitor*, larva of, origin of the brown pigment in the integument of the (GORTNER), A., ii, 632.
- Tennantite**, from Binn, Switzerland (PRIOR), A., ii, 781.
- Tephrosia purpurea*, glucoside from (CLARKE and BANERJEE), T., 1833; P., 213.
- Terephthalic acid**, dimethyl ester (RUFF and MÜNTER), A., i, 395.
- Terephthalic anhydride** (BUCHER and SLADE), A., i, 38.
- Ternary system**, sodium sulphate-sodium fluoride-sodium chloride (WATERS), A., ii, 775.

- Ternary systems** (JÄNEKE), A., ii, 699.
critical end-points in (SMITS), A., ii, 1050.
- Terpene**, monocyclic, synthesis of, from thymol (HENDERSON and SUTHERLAND), T., 1616; P., 203.
- Terpenes**, chemistry of (HENDERSON and SUTHERLAND), T., 1616; P., 203; (HENDERSON and POLLOCK), T., 6620; P., 203.
- synthesis of the (PERKIN), T., 2129; P., 97, 249; (LUFF and PERKIN), T., 2147; P., 249.
- and ethereal oils (WALLACH), A., i, 569.
- and styrenes, heats of combustion of (AUWERS, ROTH, and EISENLOHR), A., ii, 586.
- Terpene series**, syntheses in (KOMPPA), A., i, 51.
- hydrogenation in the (VAVON), A., i, 52.
- Terpinene question**, the (WALLACH), A., i, 569.
- α -Terpinene** (AUWERS; SEMMLER and SCHOSSBERGER), A., i, 53.
- Terpineol**, in bergamot oil (ELZE), A., i, 495.
- Terpinolene**, preparation of (SEMMLER and SCHOSSBERGER), A., i, 53.
- Testicle**, ox, occurrence of chlorine in (TOTANI), A., ii, 879.
- Tetany** due to ammonia in blood (JACOBSON), A., ii, 986.
- Tetra-acetylglucosyringic acid**, methyl ester (MAUTHNER), A., i, 677.
- Tetra-acetylglucosopyridinium hydr-oxide**, bromide, and hydrogen ferrocyanide (FISCHER and RASKA), A., i, 503.
- Tetra-acetyl**. See also under the parent Substance.
- Tetra-alkylammonium series**, bases of the, the double nitrites of mercury and (RAY), P., 172.
- oo'-pp'-Tetrahydroxyloxy-2,5-diphenylpyrazine** (TUTIN), T., 2515.
- $\beta\beta\beta\beta$ -Tetraisobutylacetoacetic acid**, ethyl ester (FREYLOX), A., i, 359.
- 2,2,4,4-Tetracarboxydicyclo-0,11-butane-1,3 diacetic acid**, and its esters and metallic salts (GUTHZIT and HARTMANN), A., i, 388.
- Tetradecamethylenedicarboxylic acid**, ethyl ester (BOUGAULT), A., i, 297.
- Tetraethylammonium perchlorate** (HOFMANN, ROTH, HÖBOLD, and METZLER), A., i, 818.
- ferrichloride (SCHOLTZ), A., i, 96.
- mercuri-iodide (ZIPKIN), A., i, 903.
- Tetrahydroacenaaphthalisothiophendicarboxylic acid**, dihydroxy- (HINSBERG), A., i, 335.
- 1:2:3:4-Tetrahydroacridine**, salts and derivatives of, and 7-bromo-, and 7:9-dibromo- (BORSCH, SCHMIDT, TIEDTKE, and ROTTSIEFER), A., i, 883.
- 1:2:3:4-Tetrahydroacridine-5-carboxylic acid**, and its salts and derivatives, and 7-bromo-, and 7:9-dibromo- (BORSCH, SCHMIDT, TIEDTKE, and ROTTSIEFER), A., i, 883.
- Tetrahydroacridine-6 sulphonic acid** (BORSCH, SCHMIDT, TIEDTKE, and ROTTSIEFER), A., i, 883.
- Tetrahydroatropaldehyde** (DARZEN and ROST), A., i, 856.
- Tetrahydromesobenzodanthrone**, acetyl derivative of (POTSCHWAUSCHEG), A., i, 495.
- Tetrahydroberberine**, isomeric ammonium compounds from (VOSS and GADAMER), A., i, 415.
- ethyl hydrogen sulphate, ethyl anhydro-base and its derivatives (VOSS and GADAMER), A., i, 416.
- Tetrahydroberberrubine** (FRIEDICH), A., i, 501.
- Tetrahydroellagic acid** (NIERENSTEIN), A., i, 623.
- cis-Tetrahydrofuran-2,5 dicarboxyldianilide** (LE STEUR and HAAS), T., 184.
- cis-Tetrahydrofuran-2,5 dicarboxylic acid**, its anhydride and ammonium salt (LE STEUR and HAAS), T., 183.
- Tetrahydroglyoxaline**, 2-imino- (ethyl-enequaxidine), and its salts (SCHENCK), A., i, 100.
- 1:2:3:4-Tetrahydronaphthalene**, absorption spectrum of (LEONARD), T., 1246; P., 113.
- Tetrahydro- β -naphthoic acid**, menthyl ester (RUPE and MÜNSTER), A., i, 398.
- Tetrahydro- β -naphthylamine**, action of, on the body temperature and circulation (SACHAROFF), A., ii, 433.
- Tetrahydropapaveroline**, physiological action of (LAIDLAW), A., ii, 797.
- 1:2:3:4-Tetrahydrophenazine, 1-oximino**, (BORSCH), A., i, 179.
- Tetrahydroquinoline**. See 2-Methyl tetrahydroquinoline.
- Tetrahydroquinazoline-2,4 dione**, 3-amino- (3-aminobenzoylenercarbamide), and its derivatives (KUNCKELL), A., i, 438.
- Tetrahydroquinoline**, derivatives of (KUNCKELL), A., i, 429, 635; (KUNCKELL and THEOPOLD), A., i, 506.
- ferrichloride (SCHOLTZ), A., i, 97.

- Tetrahydroquinoline, 6-bromo-, salts of, 6-bromo-8-amino-, and its derivatives, 6-bromo-8-nitro- and its nitroso-amine, 6:8-dinitro- and tri-bromo-, hydrobromide (KUNCKELL), A., i, 429.
- trinitro- (KUNCKELL), A., i, 636.
- Tetrahydrosantalene (SEMMLER), A., i, 181.
- Δ^1 - and *trans*- Δ^2 -Tetrahydroterephthalic acid, dimethyl ester of (RUPE and MUNTER), A., i, 398.
- Tetrahydrothiophen, preparation of, and its methiodide (V. BRAUN and TRUMPLER), A., i, 275.
- Tetrahydronic acid, synthesis of (FRANKLAND), T., 1316; P., 171.
- Tetraketo-2-phenyl-tetrahydro-2:1:3-benztriazole (ZINCKE and SCHARFF), A., i, 141.
- 2:4:2':4' and 3:4:2':4'-Tetramethoxybenzophenone (TAMBOUR and SCHÜCH), A., i, 559.
- 2:6:2':6'-Tetramethoxybenzophenone (V. BAeyer, AICKELIN, DIEHL, HALLENLEBEN, and HESS), A., i, 252.
- 1:3:2':3', 1:3:2':4', and 1:3:3':4'-Tetramethoxybenzylidenecoumaranones (DUMONT and TAMBOUR), A., i, 579.
- 2:6:2':6'-Tetramethoxydiphenylcarbinol (V. BAeyer, AICKELIN, DIEHL, HALLENLEBEN, and HESS), A., i, 251.
- mon'pp'*-Tetramethoxy-2:5-diphenylpyrazine, and its salts (TUTIN), T., 2510; P., 244; (TUTIN and CATON), T., 2533; P., 245.
- mon'pp'*-Tetramethoxy-2:6-diphenylpyrazine and its salts (TUTIN), T., 2511; P., 244; (TUTIN and CATON), T., 2533; P., 245.
- Tetramethoxyphenanthrene and its picrate (PSCHORN and REITZBERG), A., i, 424.
- Tetramethylaminobenzhydrol, action of hypophosphorous acid on (FOSSE), A., i, 451.
- Tetramethylaminobenzhydrylphosphinones acid (FOSSE), A., i, 451.
- Tetramethylaminobenzophenone, action of magnesium cyclohexyl bromide on (WAHL and MEYER), A., i, 134.
- 4':4''-Tetramethylamino-2'''-3'''-dimethoxytriphenylmethane, and its hydrochloride (NOELTING), A., i, 177.
- 9:9-Tetramethylaminodiphenylacenaphthenone, and its salts (ZUFFA), A., i, 862.
- 4:4'-Tetramethylaminodiphenylmethane, 2:2'-diiodo- (MASCARELLI, TOSCHI and ZAMBONINI), A., i, 831.
- 5-(4':4'')-Tetramethylaminodiphenylmethyl-3:3-bis-*p*-dimethylamino-phenyloxindole (REITZENSTEIN and BREUNING), A., i, 441.
- 5-(4':4'')-Tetramethylaminodiphenylmethylisatin, and its acetyl derivative and chloride (REITZENSTEIN and BREUNING), A., i, 440.
- 4-(or 6)-4'')-Tetramethylaminodiphenylmethyl-5-methylisatin, and its sodium salt (REITZENSTEIN and BREUNING), A., i, 441.
- 5-(4':4'')-Tetramethylaminodiphenylmethyl-7-methylisatin (REITZENSTEIN and BREUNING), A., i, 441.
- 8-Tetramethylaminodiphenylmethyl-1-naphthoic acid, and its barium salt (ZUFFA), A., i, 862.
- Tetramethylaminodiphenyl- α -naphthylmethane (ZUFFA), A., i, 862.
- Tetramethyl- α -*d*-aminohexane, and its picrate and methiodide (V. BRAUN), A., i, 821.
- 4':4''-Tetramethylamino-2'''-hydroxy-3'''-methoxytriphenylmethane, and its hydrochloride (NOELTING), A., i, 177.
- Tetramethylammonium *perchlorate* (HOFMANN, ROTH, HÖBOLD, and METZLER), A., i, 818.
- mercuri-iodide (ZINKIN), A., i, 303.
- 2:4:3':5'-Tetramethylazobenzene 2-hydrazinesulphonic acid, and its salts (TÖRGER and WESTERKAMP), A., i, 208.
- 2:4:5:6-Tetramethyl-1:3:7:9-benztriazole (BULOW and HAAS), A., i, 203.
- Tetramethyl-*p*-tobutandione, action of ammonia on (WEDERKIND and MILLER), A., i, 324.
- Tetramethyl-*p*-tobutanone, imino-, and its phenylhydrazine (WEDERKIND and MILLER), A., i, 324.
- Tetramethylchrysianiline, salts of (FISCHER and SCHMIDT), A., i, 702.
- 2:4:2':4'-Tetramethyl-1:1'-dianthraquinoyl (SCHOLL and POTCHWAUSCHEG), A., i, 272.
- 2:4:2':4'-Tetramethyldiphenyl-3:3' and 5:5'-diphthaloylic acid, and disulphonic acid of the former (SCHOLL, LIESE, MICHELSON, and GRUNWALD), A., i, 261.
- Tetramethylferrocyanide, and its derivatives (HARTLEY), T., 1966, 1725; R., 90, 210.
- Tetramethylgalactoseanilide (BRINSE and McNICOLL), T., 1454.
- 776-Tetramethylheptan-8-ol, and its phenylurethane (HALLER and BACER), A., i, 309.

- γ -Tetramethylheptan- δ one** (HALLER and BAUER), A., i, 309.
- δ -Tetramethylhexan- γ -ol, and its phenylurethane** (HALLER and BAUER), A., i, 220.
- δ -Tetramethylhexan- γ -one** (HALLER and BAUER), A., i, 220.
- Tetramethyl mannoseamide** (IRVINE and McNICOLL), T., 1452.
- Tetramethylnaphthalene**, absorption spectrum of (HOMER and PURVIS), T., 280; P., 5.
- δ -Tetramethylpentan- γ -ol, and its formyl derivative and phenylurethane** (HALLER and BAUER), A., i, 220.
- δ -Tetramethylpentan- γ -one** (HALLER and BAUER), A., i, 220.
- 2:4:2':4'-Tetramethyl-5:5'-phthaloyldiphenyl-3-phthaloylic acid** (SCHOLL, LIESE, MICHELSON, and GRUNEWALD), A., i, 264.
- Tetramethylthiocarbamide** (BILLETIER), A., i, 545.
- Tetramethyluric acid**, degradation of (BILITZ), A., i, 522.
- Tetra- β -naphthylethane**, and its oxide (SCHMIDLIN and HUBER), A., i, 833.
- Tetraphenylacetone** (SNEDELEY), T., 1491; P., 149.
- $\alpha\alpha$ -Tetraphenylbutadiene, and its di-bromide** (STAUDINGER and BUCHWITZ), A., i, 47.
- $\beta\beta$ -Tetraphenyl- $\Delta\gamma$ -butinen- $\beta\epsilon$ -diol** (DUPONT), A., i, 456.
- 1:2:4:5-Tetraphenyl-3:6-dihexylhexahydro-1:2:4:5-tetrazine** (KASSOW and BAUMANN), A., i, 79.
- Tetraphenyldiglycolyl chloride** (STOLLS), A., i, 738.
- 2:2:5:5-Tetraphenyl-2:5-dihydrofuran** (PURDIE and ARUP), T., 1542; P., 199.
- α -Tetraphenylethane, monochloro-, and $\alpha\delta$ -dichloro-** (SCHMIDLIN and v. ESCHER), A., i, 869.
- $\alpha\delta$ -dichloro-, preparation of** (FINKELSTEIN), A., i, 469.
- $\alpha\alpha\beta$ -Tetraphenylhexa- $\Delta\gamma\epsilon$ -triene, and its tetrabromide** (STAUDINGER and BUCHWITZ), A., i, 47.
- Tetrazens** (HOFMANN, HOCK, and ROTH), A., i, 446.
- Tetrazole from azoimide** (DIMROTH and FESTER), A., i, 645.
- Tetrazole, 1-hydroxy-** (PALAZZO), A., i, 842.
- Tetrazoles**, synthesis of (DIMROTH and MERZBACHER), A., i, 897.
- Tetrazolylazacetacetic acid, ethyl ester, and its phenylhydrazone** (BÜLOW), A., i, 81.
- 4-Tetrazolylazo-1-phenyl-3-methyl-5-pyrazolone** (BÜLOW), A., i, 81.
- Thalidrum** order, presence of hydrocyanic acid in the (VAN ITALLIE), A., ii, 534.
- Thallium**, ultra-red line spectrum of (PASCHEN), A., ii, 1014.
- relation of, to the alkali metals (TROTTON), A., ii, 127.
- and silver, liquid-crystalline phases of the monohalides of (STOLTZENBERG and HUTH), A., ii, 295.
- Thalium alloys**, with mercury, electrochemical investigation of (RICHARDS and WILSON), A., ii, 384.
- Thallium salts**, toxicity of (SWAIN and BATEMAN), A., ii, 229.
- Thallium iridichloride and iodochloride** (DELEPINE), A., ii, 34.
- double fluorides of univalent (EPHRAIM and HEYMANN), A., ii, 37.
- manganesomanganic, antimony, tantalum and tungsten fluorides (EPHRAIM and HEYMANN), A., ii, 37.
- selenate (GLAUSER), A., ii, 504.
- zinc sulphate and selenate (TUTTON), A., ii, 127.
- Thallium**, new reaction for (TANATAR and PETROFF), A., ii, 350.
- Thallium electrode**. See Electrode under Electrochemistry.
- Thalioacetylacetone** (KROWSKI), A., i, 361.
- Thehaine**, formation of pyrene from (FREUND), A., i, 631.
- Thehenine**, constitution of (PSCHORR), A., i, 423.
- Theobromine and caffeine**, comparative toxicity of (VELEY and WALLER), A., ii, 986.
- Theophylline- β -acetic acid and its ethyl ester** (FARBENFABRIKEN VORM. F. BAYER & CO.), A., i, 79.
- Thermal analysis**. See Analysis.
- Thermal expansion**. See under Thermochemistry.
- THERMOCHEMISTRY** :—
- Thermochemistry**, recent investigations in (RICHARDS), A., ii, 19.

- Thiocarhamidoacetylphenylisocarbazine (FREKENS and FÖRSTER), A., i, 191.
- Thiocarbonates, action of ammonia and amines on (DUFFINE and SHVING), A., i, 720.
- Thiocyanates, and other salts, molecular refraction of (DIXON and TAYLOR), T., 927; P., 99.
- in tobacco smoke (TITUS), A., ii, 163.
- Thiocyanic acid, oxidation of, by salt of trivalent metals (BOSETOVANSKY), A., i, 825.

- Thiocyanato-. See under the parent Sub-
stance.
- 2,2'-Thiodibenzic acid (2,2'-dicarboxy-
diphenyl sulphide), and its methyl and
ethyl esters (MAYER), A., i, 261.
- Thiodiglycollamide-phenyl and -p-tolyl-
hydrazides (FRERICHS and FÖRSTER),
A., i, 192.
- Thiodiphenylamine, bromo- and
tetra-chloro- (PAGE and SMILES), T.,
1118.
- 6-Thio-2-ethylthiol-5-methylpyrimidine
(WHEELER, McFARLAND, and STOREY),
A., i, 139.
- Thioglycoll-phenyl and -p-tolylhydra-
zide (FRERICHS and FÖRSTER), A., i,
192.
- Thioglycols, preparation of (BRAUN), A.,
i, 13.
- "Thioindigo." See Bisoxylthionaph-
then.
- Thiolbenzoic acid, modifications of
(HINSBERG), A., i, 260.
derivatives of (MAYER), A., i, 260.
esterification of, by alcohol (REID),
A., i, 481.
- Thiolbenzoic acid, di-iodo-2-amino-
(WHEELER and JOHNS), A., i, 382.
- Thiol-2,4-dimethylbenzoic acid (FAR-
WERKE VORM. MEISTER, LUCIUS, &
BRÜNING), A., i, 263.
- Thioldimethylerucic acid, hydroxy-
(BURKHARDT), A., ii, 799.
- Thiol-1:4-diphenylendo-oxydihydro-
triazole, disulphide, sodium, and
benzoyl derivatives (BUSCH, REIN-
HARDT, and LIMPACH), A., i, 142.
- Thiol-4-ketopenthiophenthiophen-5-
carboxylic acid, 3-hydroxy-, ethyl
ester (AFITZSCH and KESLER), A., i,
410.
- Thiol- and 8-Thionaphthalene-1-carboxylic
acids (FARWERKE VORM. MEISTER,
LUCIUS, & BRÜNING), A., i, 263.
- Thiol-5-(or 4-)phenyl-4-(or 5-)ethyl-
glyoxaline (HILDESHEIMER), A., i,
891.
- Thiols, formation and decomposition of
(SABATIER and MAILHE), A., i,
536.
preparation of, from alcohols by cata-
lysis (SABATIER and MAILHE), A.,
i, 456.
- Thiol-p-toluic acid (FARWERKE VORM.
MEISTER, LUCIUS, & BRÜNING), A., i,
263.
- Thionaphthen, 4-chloro-2-hydroxy-
(BADISCHE ANILIN- & SODA-FABRIK),
A., i, 764.
- Thionaphthenquinone-p-dimethylamino-
2-anil, and its hydrochloride, and 5-
and 7-chloro- (PUMMERER), A., i, 510.
- Thionaphthenquinone-p-phenylamino-2-
anil, and its hydrate and hydro-
chloride (PUMMERER), A., i, 511.
- Thioncarbamie acid, propyl ester (DELÉ-
PINE and SCHVING), A., i, 721.
- Thionyl chloride. See under Sulphur.
- Thiophen, absorption spectrum of
(PURVIS), T., 1648; P., 201.
- Thiophens, preparation of, by the action
of ammonium sulphide on aliphatic
aromatic ketones (WILLGERODT and
SCHOLTZ), A., i, 392.
- Thiophen-2,5-dicarboxylic acid, 3,4-di-
hydroxy-, ethyl and methyl esters
(HINSBERG), A., i, 335.
- γ-Thiophenoylpentane (FREUND and
FLEISCHER), A., i, 492.
- Thiophosphates. See under Phosphorus.
- Thiosalicic acid. See o-Thiolbenzoic
acid.
- 2- and 6-Thiotbymine, and salts of
(WHEELER, McFARLAND, and STOREY),
A., i, 139.
- Thio-p-toluinometbyl ether methyl
hydrogen sulphate (MATSU), A., i,
695.
- Thiourazoles, isomeric (BUSCH, REIN-
HARDT, and LIMPACH), A., i, 142.
- Thioxanthone, new syntheses of, and
its derivatives (DAVIS and SMILES),
T., 1296; P., 93, 174; (SMILES),
P., 342.
perchlorate (GOMBERG and CONE), A.,
i, 871.
- 4-bromo- (GOMBERG and CONE), A., i,
871.
- 2-chloro-4-nitro-, and 1-chloro-4-
nitro- (MAYER), A., i, 262.
- hydroxy- (DAVIS and SMILES), T.,
1296; P., 174.
- 2,4-dinitro- (MAYER), A., i, 262.
- Thloxanthone-4-carboxylic acid, and its
amide and methyl ester (MAYER), A.,
i, 261.
- Thorium (v. WARTENBERG), A., ii, 134.
in the atmosphere (KURZ), A., ii, 476.
disintegration products of, in the
atmosphere (PACINI), A., ii, 374.
amount of, in sedimentary rocks
(JOLY), A., ii, 723, 969.
- radioactivity of halogen and oxy-
halogen compounds of (CHAUDIER
and CHAUVENET), A., ii, 174.
- rate of emission of α-particles from
(GEIGER and RUTHERFORD), A.,
ii, 917.
- emanation, α-particles expelled from
the (GEIGER and MARSDEN), A., ii,
92.
- Thorium salts, preparation of, and puri-
fication of, by means of the sulphate
(KOPPEL and HOLTkamp), A., ii, 717.

- Thorium chloride**, compounds of, with ammonia (CHAUVRNET), A., ii, 872.
 picrate, hippurate and basic chloroacetates (KARL), A., i, 552.
 selenate (WYROUOFF), A., ii, 417.
 sulphate (BARRE), A., ii, 781.
 basic (HAUSER), A., ii, 1075.
 heat of hydration and vapour pressure of the hydrates of (KOPPEL), A., ii, 691.
 double sulphates and decomposition of the normal sulphate by water (BARRE), A., ii, 718.
Thorium, estimation of, in monazite (MISGAYE), A., ii, 78; (MEYER and SPEYER), A., ii, 459.
Thorium-X, new β -radiation from (HAHN and MEYNER), A., ii, 566.
d. **Three- α -*tr*hydroxyvaleric acid**
 phenylhydrazide of (NEF), A., i, 713.
d. and *l*. **Three- α -*tr*hydroxyvaleric acids** and their salts and derivatives (NEF), A., i, 713.
d. **Three- α -*d*hydroxyvalerolactone** (NEF), A., i, 713.
Thrombin (HOWELL), A., i, 793.
a. **Thujadicarboxylic acid**, esters and amide of, and ammonium salt of the latter (THOMSON), T., 1512; P., 178.
Thujene, derivatives of (KONDAROFF and SKWORZOFF), A., i, 754.
Thujone. See Tanacetone.
Thulium (JAMES), A., ii, 412.
Thymine, preparation of (WHEELER, McFARLAND, and STORV), A., i, 138.
 sodium, mercuric, silver, and lead salts (MYERS), A., i, 344.
Thymol, bactericidal value of (SCHMIDT), A., ii, 882.
 iodide, estimation of (ELYOYE), A., ii, 905.
p. **Thymol** (3-hydroxy-1-methyl-4-isopropylbenzene) (GUILLAUMIN), A., i, 375.
Thymomenthone, dibromo- (BRUNEL), A., i, 478.
Thymomenthonecarboxylic acid (GARDNER, PREKIN, and WATSON), P., 137.
a. **Thymotic acid** and its silver and sodium salts, methyl and ethyl esters, and two isomeric thymonides (SPALLINO and PROVENZANI), A., i, 38.
o. **Thymyloxyacetic acid** (BIRAL and TIEFFENAU), A., i, 375.
p. **Thymyl 3-oxoacetic acid** (GUILLAUMIN), A., i, 376.
Thyreoglobulin, iodine (OSWALD), A., i, 793.
Thyroid, possible relationship between the pituitary and the (SIMPSON and HUNTER), A., ii, 428.
Thyroid, internal secretion of the (CARLSON and WOELFEL), A., ii, 526.
 fat-splitting and oxidising ferments of the, and influence of the, on lipolytic processes of the blood (JUSCHENKO), A., ii, 526.
 estimation of iodine in the (SHIBELL), A., ii, 62.
Thyroidectomy, and the anaemic destroying power of the liver (CARLSON and JACOBSON), A., ii, 264.
 effect of, on immunity in rabbits (FRIEDSTAD), A., ii, 526.
 and the resistance of rats to morphine poisoning (OLDS), A., ii, 797.
Tiglic aldehyde, action of organo-magnesium compounds on, and the optic behaviour of the products (ARMANN), A., i, 454.
Tin, behaviour of bismuth toward (MASING and TAMMANN), A., ii, 419.
 influence of, on the iron-cobalt system (GORENS and ELLINGSEN), A., ii, 206.
 electrolytic precipitation of (TASZTOR), A., ii, 459.
 mixed halogen compounds of (AUGER), A., ii, 133.
 halogenides, additive compounds of and carbonyl compounds (PERIFF, HALPERIN, PERO, and SCHWARKOFF), A., i, 862.
Tin alloys with antimony, analysis (McCAY), A., ii, 1003.
 with lead, constitution and heat contents of (GREUTLER), A., ii, 124.
 heat of solidification of (MAZZOTTI), A., ii, 890.
 with mercury, electro-chemical investigation of (RICHTER and WILSON), A., ii, 384.
Stannic acids, isomerism of (MCCLENNUGH), A., ii, 41.
Stannous salts, behaviour of in towards solutions of (TRIEB and KELLER), A., ii, 982.
Tin organic compounds (PERIFF, LEHNHART, LUTTENSTEIN, PRADE, SCHNEEMANN, and TRIER), A., i, 724; (PERIFF, FRIEDMANN, and REKAT), A., i, 468.
Tin tetra-*p* tolyl (PERIFFER, LEHNHART, LUTTENSTEIN, PRADE, SCHNEEMANN, and TRIER), A., i, 724.
Tin, estimation of, in white metal electrolysis (SCHNEEMANN), A., ii, 1115.
 estimation of, electrolytic, in bronzes, and other alloys (SCHMANN and ARNOULD), A., ii, 549.
 estimation of, in presence of antimony (SANCHEZ), A., ii, 1003.

- Tin**, arsenic and antimony, estimation of, by means of potassium ferricyanide (PALMER), A., ii, 547.
separation of, from antimony, by distillation (PLATO), A., ii, 903.
- Tin group**, separation of metals of the (CAVEN), P., 176.
- Tissue**, muscular, of frogs, influence of different substances on the gaseous exchange of the surviving (THUNBERG), A., ii, 54, 523.
extracts made at high temperatures, reversed activity of (COLLINGWOOD), A., ii, 139.
- Tissues**, surviving, formation of carbon dioxide in (HANSEN), A., ii, 56.
glycolytic processes in the (DE MEYER), A., ii, 631.
the relationship of diastatic efficiency to glycogen content in (BLACKMAN), A., ii, 142.
influence of certain toxins and anti-toxins on the oxidising and reducing capacities of the (PITINI), A., ii, 631.
- animal**, analysis of (KOCH), A., ii, 78;
(KOCH and MANN; KOCH and CARR; KOCH and UFFSON), A., ii, 79.
manganese in (BRADLEY), A., ii, 979.
estimation of sodium iodide in (HANZLIK), A., ii, 743.
animal and vegetable, detection of peroxidolytic enzymes in (ABDERHALDEN), A., ii, 666.
- Titanic acid**. See under Titanium.
- Titanium** (WEISS and KAISER; HUNTER), A., ii, 302.
spectrum of (FIEDIG), A., ii, 170.
effect of pressure on the arc spectrum of (ROSSI), A., ii, 363.
ozo-salts of (MAZZUCHELLI and PANTANELLI), A., i, 651.
- Titanium** minerals, zirconia and erbia from (HOFMANN), A., ii, 1073.
- Titanic acid**, solution and precipitation of (BORNEMANN and SCHIRMELSTEIN), A., ii, 1073.
estimation of, in ilmenite (RÖER), A., ii, 78.
reactions for (PICARD), A., i, 67;
(FENTON), A., ii, 241.
estimation of (GEMMELL), A., ii, 550;
(BARNEBEY and ISHAM), A., ii, 901.
- Toads**, immunity of, to their own poison (FÜHRER), A., ii, 1096.
- Tobacco** culture, production of nicotine in (SCHLESING), A., ii, 743.
- Tobacco** smoke, cyanogen compounds in (TÖTH), A., ii, 423.
thiocyanates in (TÖTH), A., ii, 165.
- (*Tolyl compounds, Me = 1.*)

- Toluenesulphonic acid, *p*-aminobenzenesulphonic acid (MORGAN and PICKARD), T., 57.
- p*-Toluenesulphonylaziminotoluene (ÜLLMANN and GROSS), A., i, 886.
- p*-Toluenesulphonyl bromide, and 3-bromo-, chloride (ZINCKE and FROMMERT), A., i, 315.
- p*-Toluenesulphonyl chloride 2-nitro-, electrolytic reduction of (FRIEDER and BRENDLE), A., i, 20.
- p*-Toluenesulphonylmethyl 3-amino-*p*-toluidide (ÜLLMANN and GROSS), A., i, 884.
- p*-Toluenesulphonylmethyl 3-nitro-*p*-toluidide (ÜLLMANN and GROSS), A., i, 886.
- p*-Toluenesulphonylmethyl 3:5-dinitro-*p*-toluidide (ÜLLMANN and GROSS), A., i, 886.
- p*-Toluenesulphonylmethyl-*p*-phenylenediamine (AKTIEN-GESELLSCHAFT FÜR ANILIN-FABRIKATION), A., i, 727.
- p*-Toluenesulphonylnaphthastyril (ÜLLMANN and CASSEBE), A., i, 201.
- Toluenesulphonic acid, *p*-nitroaniline (MORGAN and PICKARD), T., 56.
- p*-Toluenesulphonyl 3-nitro-*p*-toluidide (ÜLLMANN and GROSS), A., i, 886.

(Tolyl compounds, $Me=1$.)

- p*-Toluenesulphonyl 3:5-dinitro-*p*-toluidide, nitro- (ÜLLMANN and GROSS), A., i, 888.
- Toluenesulphonyl-*p*-phenylenediamine (MORGAN and PICKARD), T., 56.
- Toluenesulphonyl-*p*-phenylenediazide (MORGAN and PICKARD), T., 57.
- p*-Toluenesulphonyltoluene 3:4-diamine, and its hydrochloride (ÜLLMANN and GROSS), A., i, 886.
- o*-, *m*-, and *p*-Toluenic acid, isomeric esters of (COHEN and DUDLEY), T., 1719.
- m*-Toluenic acid, 5-iodo-4-amino-, and its ethyl ester (WHEELER and HOFFMAN), A., i, 666.
- p*-Toluenic acid, *p*-tolyl ester of (MACARELLI and RUSSI), A., i, 746.
- o*- and *m*-Toluidine, absorption spectra of (PURVIS), T., 1551.
- o*-Toluidine, 5-iodo-6-nitro-, and 3:6-di-iodo- (WHEELER and BRATTLECH), A., i, 663.
- m*-Toluidine, 2-iodo-, and its acetyl derivative (WHEELER and LIDDLE), A., i, 18.
- 4-iodo-, phenylthiocarbamide derivative, 5-iodo-, and 1:5-di-iodo-, and their acetyl derivatives (WHEELER and SCHOLZ), A., i, 663.
- 2:4-di-iodo-, and 2:4:6-tri-iodo-, and their derivatives (WHEELER and HOFFMAN), A., i, 662.
- 2:6-di-iodo-, and its hydrochloride (WHEELER and BRATTLECH), A., i, 663.
- p*-Toluidine, and its condensation product with acetaldehyde, absorption spectra of (PURVIS), T., 644; P., 56.
- 3-iodo-, and its hydrochloride, oxalate, and acetyl and benzoyl derivatives (WHEELER and LIDDLE), A., i, 17.
- 5-iodo-3-nitro- (WHEELER and SCHOLZ), A., i, 663.
- 3:5-di-iodo-, acetyl derivative of (WHEELER and LIDDLE), A., i, 18.
- Toluidines, xylenes and nitrotoluenes freezing mixtures of (FISHER), A., i, 309.
- o*-Toluidine 5-sulphonic acid, 3-chloro- (RADSCHE ANILIN- & SOJA-FABRIK), A., i, 271.
- Toluidinobenzoic acid, 3:5-dinitro- (ZINCKE), A., i, 556.
- 7-*p*-Toluidine 3:6-dimethylphenoxazine, and its derivatives (HORNEMANN), A., i, 779.
- 2- (or *m*-) Toluylobenzene acid, 3:6-dichloro-3'-(or 2'-)hydroxy-, and 3:6-dichloro-5'-(or 6'-)hydroxy-, its sodium salt and its monobromine derivative (WALSH and WEIZMANN), T., 689.
